Fig. 1 illustrates a limb which developed in association with a distal wound on the dorsal surface. (The figures are labelled with *D* and *P* for distal and proximal.) In this case, the axes appear to be identical with those of the 'mother' limb. Those accessory limbs which develop in association with wounds which are other than distal begin their development in the direction of the wound and later, as their development progresses, tend to adjust to the axes of the 'mother' limb. For example, accessory limbs formed on the dorsal surface in association with proximal wounds follow the pattern described in a previous paper[4]. They originally grow proximad, then straighten up, with a concavity usually on their proximal surface, and finally shift to a more distal direction, the concavity normally becoming filled in. Those which form with anterior or posterior wounds on the dorsal surface tend also to grow initially in the direction of the wound and then later to shift more distad. Fig. 2 shows a limb growing in association with an anterior wound. At the time this supernumerary was photographed it was changing toward a distal direction.

Only one accessory structure of multiple character was obtained from a ventral surface distal wound situation, and it was impossible to judge its axial relationships. Fig. 3 is strikingly illustrative of an accessory structure formed in association with a proximal wound on the ventral surface, which began its development in a proximal direction and subsequently shifted so that its entire distal portion became hooked around and grew almost directly distad.

Implant-induced accessory limbs, then, appear to follow Barfurth's rule in that the insertion wound supplies to the morphogenetic system what is in effect an oblique amputa-

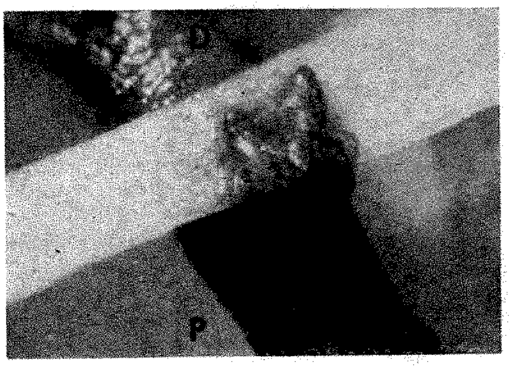

Fig. 1. Implant-induced accessory limb which formed in association with a distal insertion wound on the dorsal limb surface. Its axes correspond with those of the 'mother' limb. (× *c.* 40)

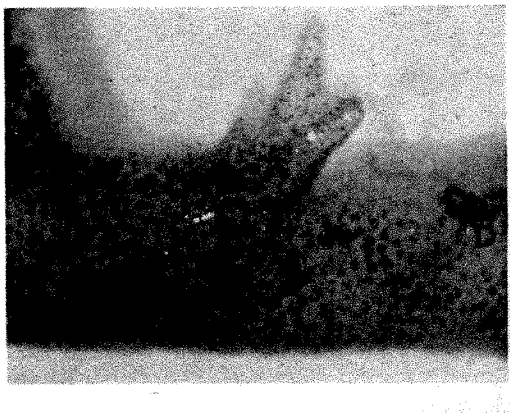

Fig. 2. Implant-induced accessory limb which formed in association with an anterior insertion wound. Its axis, although originally entirely anteriad, had shifted somewhat distad. (× *c.* 40)

tion surface and the original blastemal polarity is that of this oblique surface. Afterwards, as development progresses, the growing accessory limbs tend to adjust to the polarity of the 'mother' structure so that in their advanced stages they tend to deviate only slightly from it.

Multiple accessory limbs are of particular interest, since if the growth-centres are in close association, they tend to follow Bateson's rule and mirror-image. If their centres are so close as to form a common base external to the level of the limb surface, one obtains 'hydra-like' accessory structures where as many as 7 digits have been found arranged in a whorl around the apex of the stalk. Fig. 4 shows two such formations on the same host.

Other situations have been found in which the developmental centres fail to join external to the surface of the limb but established a common base internally with the digits arranged much like the spikes on a crown. One of these 'corona-like' arrangements is illustrated in Fig. 5. These digital arrangements have in both instances been interpreted by us as having resulted from mirror-image development of multiple morphogenetic systems which are so close as to be interacting. In any event, it is known that they result when secondary wounds are established near the insertion wounds through the activities of the implants. This type of secondary wound formation by implants has previously been reported[4]. The foregoing postulate that these formations are really multiples further obviates the necessity of supposing that a single blastema has been created capable of forming a greater number of digits than one would normally find on an amphibian forelimb. Such an occurrence would be contrary to previous experiences in the limb regeneration field. Histological examination of the bases does indeed show multiple skeletal elements.

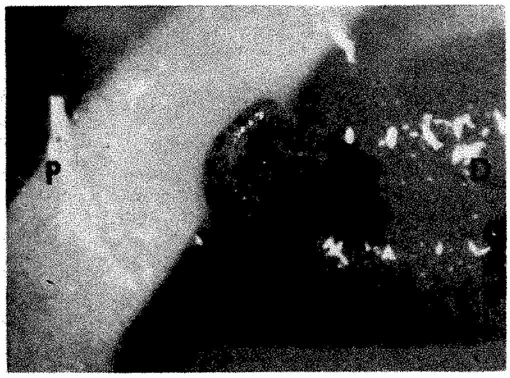

Fig. 3. Implant-induced accessory limb which formed in association with a proximal insertion wound on the ventral limb surface. Note that the entire distal end had hooked about and was heading toward the hand of the 'mother' limb. (× c. 40)

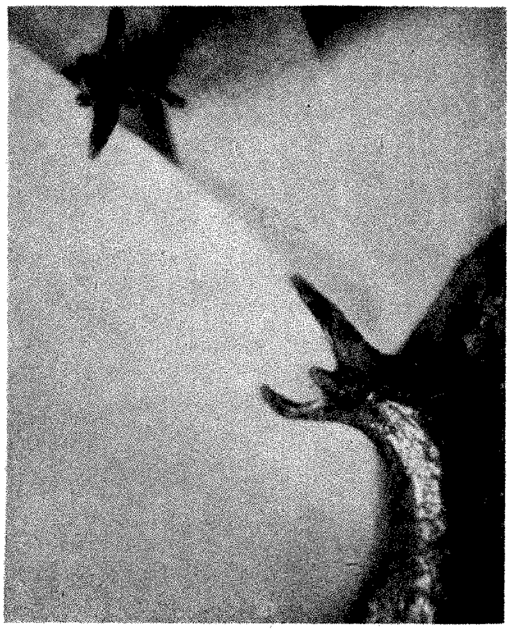

Fig. 4. Two 'hydra-like' accessory limb structures. These appear to arise from multiple-interacting morphogenetic systems which form a common stalk external to the limb surface. (× c. 40)

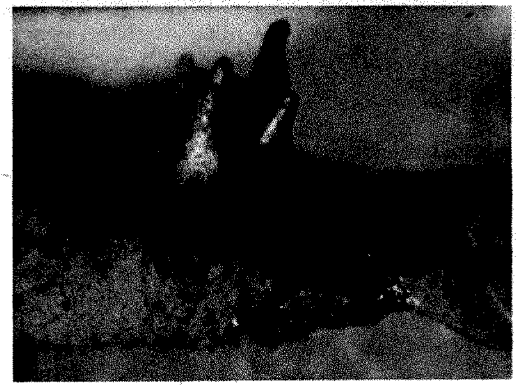

Fig. 5. An example of a 'corona-like' formation. These appear to arise from multiple-interacting morphogenetic systems which form a common base internal to the limb surface. (× c. 40)

Hæmoglobin in Barnacles

HÆMOGLOBIN is known from many groups of Crustacea, excluding Malacostraca; but it has not previously been found in the non-parasitic Cirripedia[1]. It is, therefore, interesting to record the occurrence of hæmoglobin in *Balanus perforatus* Bruguière, a common intertidal barnacle of southern Britain, south-west Europe, the Mediterranean and north-west Africa.

When freshly collected specimens are dissected under a low-power binocular, certain of the muscles can be seen to be pale pink, though the majority are colourless. Examined with an eyepiece spectroscope, the darkest of these muscles produce faint absorption lines centred at 577 and 545 mμ, and reduction with sodium dithionite produces a single diffuse line centred at 555 mμ. These spectra are characteristic of hæmoglobin[2].

Treatment of fresh specimens with benzidine and hydrogen peroxide[3] gives a blue or brown stain in the pink muscles, the nervous system, the outer part of the gut wall and sometimes in the muscular walls of the vasa deferentia. There is no great difference between the staining of fresh and boiled specimens, indicating that tissue peroxidases are not responsible for the reaction in these organs[4]. After fixation in alcohol the distribution of the benzidine-positive muscles can be followed by dissection. They are most abundant in part of the prosoma around the adductor scutorum, but there are also some among the oblique muscles of the thorax and in the basal joints of the cirri. Of the three pairs of large muscles which depress the operculum, only the lateral depressors contain hæmoglobin, in a small number of flattened fibres on the inner side, which show up as pink when fresh. In some specimens two or three fibres of the adductor scutorum are also benzidine-positive.

From the distribution of 'pink' muscle outlined here, one may deduce that hæmoglobin is concentrated in muscles performing fairly continuous and rapid movements[5], especially in the region of the blood-pump[6]. The blood itself is very pale yellow or orange in colour, but has no perceptible absorption lines. However, it does give a slight positive reaction with both benzidine and *o*-tolidine[4], which, if not due to contamination, may indicate the presence of a low concentration of hæmoglobin.

No other species of barnacle examined has sufficient hæmoglobin to give a pink colour to the muscles; but *Elminius modestus* Darwin and *Balanus crenatus* Bruguière would appear to contain a small quantity, since some muscles of the prosoma give a positive benzidine reaction.

Moulting Behaviour of *Birgus latro*

THE moulting behaviour of *Birgus latro*, the coconut or robber crab, has never been described even though this crab has been the subject of many observations. Weins[1] reviewed these observations most recently, and Harms[2] reviewed the older literature. Neither moulting nor the moulting behaviour is mentioned in these reports with the exception of a photograph of a recently moulted *B. latro* by Harms. Furthermore, in several years of observation of *B. latro* in the Marshall Islands, exuviæ or freshly moulted crabs were never found although scores of burrows have been examined, often with the aid of local residents. Small individuals with a cephalothorax length of less than about 30 mm are relatively rarely found even when special efforts are made. Prof. Donald C. Matthews of the University of Hawaii has had similar experiences (personal communication, December 1962).

On September 21, 1961, a living *Birgus*, with a cephalothorax-length of 20·8 mm, was obtained from Mr. Emos, magistrate of Rongelap Village, Rongelap Atoll, Marshall Islands. The crab was found in the early morning in an opened coconut in a grove where copra was being prepared on Rongelap Island. The specimen was carried in a plastic jar to the University of Washington, Seattle, Washington, and put in a terrarium on October 2, 1961, where the observations reported here were made.

The temperature in the terrarium was maintained at 26°–30° C and the relative humidity ranged from about 70 to 90 per cent. A red incandescent light bulb, burning continuously, served both to supply heat and permit observations at night. Both fresh water and sea water were available to the crab at all times. Coral sand, soil, and coconut husks from Rongelap were contained separately in the terrarium. Rye grass was grown in the soil. Food was always available and consisted variously of copra, fresh coconut, bread, apples, oranges, bananas, beef and fish meal. As in Nature, the crab was omnivorous but showed a clear preference for fish meal.

During the first month in the terrarium the crab remained hidden beneath the coconut husks in the daytime and was active at night, feeding, digging and usually visiting both fresh water and sea water. On the 32nd day it hid in the soil in a burrow ending in a spherical chamber with smoothly packed walls which it had made. The tunnel leading from the chamber to the surface was filled with loose soil. The closed entrance to the burrow was scarcely distinguishable from the soil around it. Larger individuals had been observed in burrows in the field but never with the entrance closed with soil.

During the second and third months the crab continued its nocturnal activity and remained hidden and covered in the soil during the day. Its abdomen appeared distended towards the end of this period and its weight had increased from 6·8 to 7·3 g. On the 86th night the crab did not leave the burrow and remained hidden without food or water for the ensuing 30 days.

In an attempt to observe the crab while in hiding, the soil was excavated to make an opening in one side of the crab's chamber and a glass window with an opaque shutter was put in place. This attempt was unsuccessful because the crab persisted in covering the glass surfaces with moist soil even when light was excluded. These attempts at observation were discontinued for fear of disturbing the 'normal' activity of the crab.

When the crab emerged from the burrow the length of the cephalothorax had increased from 20·8 to 22·7 mm. The crab continued to follow the pattern of alternating hidden and active periods (Fig. 1). During the active period it fed at night and hid during the day, sometimes in its burrow and sometimes under coconut husks. Whenever the burrow was occupied the entrance was found plugged with soil, which probably explains why small open burrows investigated in the field were always found empty.

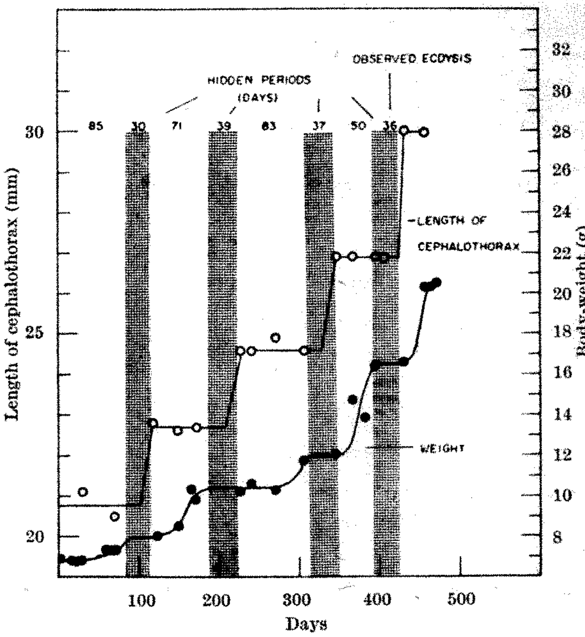

Fig. 1. Growth and moulting cycle of *Birgus latro* in a terrarium

A year after being brought to the Laboratory the crab had completed three hidden periods, and was transferred to a larger terrarium in which four clear celluloid trays containing either sand or soil were placed. The trays, which were about 20 cm × 25 cm × 10 cm deep, were suspended on stainless-steel racks so that they could be removed from the terrarium and observed from below and all sides. Within a few days the crab excavated a new chamber with one side a few millimetres from a lower corner of a tray containing soil. A flap was cut in the celluloid and folded back to afford a view into the chamber. A thin layer of soil adhered to the flap, which was pushed back in place and sealed with tape. Three weeks after the crab had entered its fourth hidden period, the flap was opened and the crab was observed daily.

Ecdysis occurred on the 28th day of hiding. The freshly moulted crab was pale blue, fading to near white in proximal areas. The following day the colour had become much darker, approaching the colour of the exuviæ, and a portion of the carapace of the exuviæ had been consumed. Day by day the exuviæ were consumed, the last remaining part being a claw. The night following the 36th day the crab emerged from hiding and at the time of writing has continued in an active period.

In 463 days this young *B. latro* moulted four times, increased in cephalothorax length from 20·8 to 30·0 mm, and in weight from 6·8 to 20·2 g (Fig. 1).

If the assumptions are made that this rate of growth remains constant and approximates that found in Nature, then specimens of *B. latro* with cephalothorax lengths in excess of 100 mm, which are common, must be about five years old.

This work was carried out under contract *AT* (45–1) 1385 with the U.S. Atomic Energy Commission.

Identification of Species of *Scenedesmus*

AMONG the organisms frequently encountered in investigations of freshwater habitats are members of the genus *Scenedesmus*. Species are delimited on the basis of the size and shape of the cells, as well as position and number of spines, if present. Although Smith[1] in his monograph of the genus shows some variation in these characters, one can, with some degree of confidence, identify species quite easily.

However, when one reviews other literature concerning identification of species, especially the monograph of Chodat[2], as well as earlier supporting work by Chodat and others, one finds that these investigators had pointed out the extreme variability found in many *Scenedesmus* species. The bulk of this earlier work centred on the ability of these organisms, while in culture, to fragment into unicellular forms which resemble *Chlorella*, *Raphidium* (*Ankistrodesmus*), *Oocystis*, etc., or to form a *Dactylococcus*-like stage. Chodat emphasized that one must culture these organisms in order to determine correctly their taxonomic position. The formation of 100 per cent unicells by *S. dimorphus* in a two-membered culture with a soil bacterium[3], as well as the occurrence of a *Dactylococcus*-like stage when the soil alga was cultured in yeast extract[4], were reported.

Recently we encountered another extremely variable *Scenedesmus* species, *S. longus*, and have examined it in unialgal, bacteria-free culture. All observations discussed are with this axenic culture. When grown in liquid medium of inorganic composition under the usual laboratory conditions, the organism does not appear to be a *Scenedesmus*. Almost all the cells of the culture are unicells bearing three or four spines at each pole. When the organism is in this condition, it could be confused easily with *Chodatella subsalsa*. In fact, the unicell fits the description of the latter exactly.

By altering the conditions of growth, for example, culture on firm agar, or by use of a thermal shock, the percentage of cœnobes was found to increase markedly, almost to the exclusion of unicells. A three-day-old culture grown on 2·5 per cent inorganic agar at 22° C produced 98·6 per cent cœnobia. Only then could the organism be recognized as *Scenedesmus longus*. Although there was some variability in spine number and location, the majority of the cœnobes had the typical six spines.

The organism was also grown in soil extract[5]. This medium has been used in the past not only to supply nutrients absent in basal inorganic media, but also in an attempt to simulate natural conditions. Apparently some organisms exhibit the form seen in field collections only when grown in soil extract or in soil-water bottles[5]. When the organism described here was grown in liquid culture in soil extract, the majority of the forms were unicellular, with the cœnobe present only in the bottom of the culture. In addition, numerous unicells were suspended in the liquid. Cell size, shape and spine condition did not vary from that described here.

Further experimentation with *S. dimorphus* demonstrated that one can stimulate the production of unicells in a number of complex media. The role of an organic carbon source in reducing *S. acutus* to the unicellular condition was first reported almost 75 years ago[6].

Although these investigations have been conducted in the laboratory and one can now only speculate as to the extent of variability in Nature, we believe that pleomorphism could exist in Nature. Growth of *S. longus* in soil extract indicates that in a body of water the unicellular form might be abundant in the plankton, whereas the cœnobe could be found in bottom sampling. Reports by Prescott[7] of the occurrence of both *S. longus* and *C. subsalsa* in the lakes of Wisconsin and Michigan give some support to this argument.

With *S. dimorphus* it also appears that the introduction of organic waste in a pond or stream might change the morphology of the organism. If sufficient numbers of bacteria were present, cœnobe formation would be affected[3].

Apparently there are many species of *Scenedesmus* in which cœnobe formation is quite stable. The fact that Smith made no mention of pleomorphism in pure culture studies connected with his monograph attests to this[1].

Even though we know little, if anything, of the extent to which pleomorphism in *Scenedesmus* exists in Nature, we re-emphasize the word of caution of Chodat concerning precise identification of species of *Scenedesmus*. For a better understanding of variability in this genus field identification of unicellular and cœnobial stages from the same site, followed by pure culture studies, appear essential.

A Fungistatic Action of Coumarin

VAN SUMERE *et al.* showed that coumarin affects the germination of wheat stem rust uredospores[1], and Bellis showed[2] that *Penicillium jenseni* and *P. nigricans* are able to grow on a modified Czapek's nutrient medium containing coumarin as the only one carbon source. So far as I am aware, no other experiments have been done to examine the ability of coumarin to regulate the growth of moulds*, in spite of the fact that some fungi normally produce coumarin precursors and derivatives[3], and the level of coumarin-like substances increases in the fungus-attacked cell[4].

Cultures of *Aspergillus niger E*–32, *Penicillium glaucum* and *Rhizopus nigricans* were obtained by dropping 0·1 ml. of spore suspension into 100-ml. Erlenmeyer flasks containing 25 ml. of nutrient media with coumarin in proper concentration. After a suitable period of time of incubation at 26° C mycelia were taken out of flasks, dried for 12 h at 105° C and weighed. Two different nutrient media were used: (*a*) yeast water supplemented with 4 per cent of glucose[5]; (*b*) a synthetic medium consisting of glucose, 45·0 g; $NaNO_3$, 4·5 g; KH_2PO_4, 3·0 g; KCl, 0·75 g; $MgSO_4.7H_2O$, 0·75 g; $FeSO_4$, 0·02 g; distilled water up to 1 l. (ref. 6). The results were analysed statistically for significance at $P = 0·05$.

The visual examination revealed that coumarin in higher concentrations (100–1,000 p.p.m.) inhibits or markedly retards the germination of spores (lengthening of lag-phase). The detail picture of effects depends on the kind of mould and nutrient medium used. The most sensitive are spores of *A. niger*; these did not germinate in yeast water containing 1,000 p.p.m. of coumarin, and under the influence of 100 p.p.m. they germinated 20–30 h later than did the controls. In a synthetic medium, however, coumarin in concentrations of 1–10 p.p.m. exerts an insignificant stimulatory effect on germination of *A. niger*.

Spores of *P. glaucum* are much more resistant. Coumarin at a concentration of 100 p.p.m. only slightly retards their germination, and spores in flasks containing 1,000 p.p.m. of coumarin germinate 20–30 h later than control ones.

Germination of *R. nigricans* spores was considerably stimulated by 5–10 p.p.m. of coumarin dissolved in yeast water; an insignificant retardation occurred only at concentrations 500–1,000 p.p.m.

It follows from the curves in Figs. 1 and 3 that coumarin exerts only an inhibitory effect on dry matter accumulation of *A. niger* and *P. glaucum* mycelia cultivated on yeast water; the former mould is much more sensitive than the latter one. The analysis of results reveals that 50 p.p.m. appears to be a threshold concentration of coumarin for normal growth of *A. niger*, and 100 p.p.m. for *P. glaucum*. Below this quantity the growth is slightly affected; to the contrary the more concentrated solutions of coumarin are markedly inhibitory. This inhibition is transient, however, and after a suitable period of time moulds seem to develop normally, though slowly.

According to the retardation of growth the sporulation is also affected by coumarin, particularly in the case of *A. niger*.

Different results are observed on a synthetic nutrient medium (Figs. 2 and 3). In this case the fungi are much more sensitive to coumarin, as a rule. Also the picture is much more complicated owing to appearance of stimulation of growth of mycelia cultured on relatively diluted solutions of coumarin. When the threshold concentration is exceeded, the inhibition of growth is expressed much more sharply than on the yeast water.

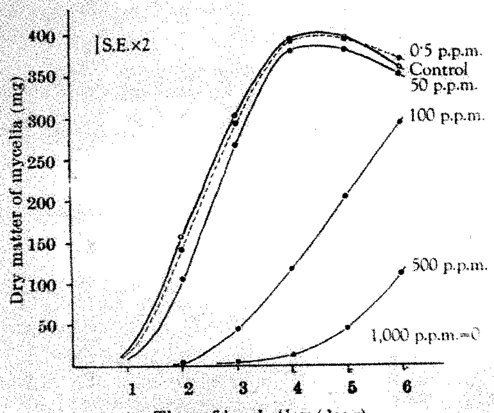

Fig. 1. Effect of coumarin on the growth of *A. niger* cultured on the yeast water containing 4 per cent of glucose

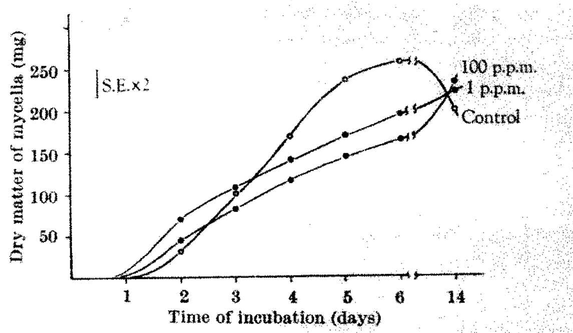

Fig. 2. Growth of *A. niger* on the synthetic nutrient medium supplemented with coumarin

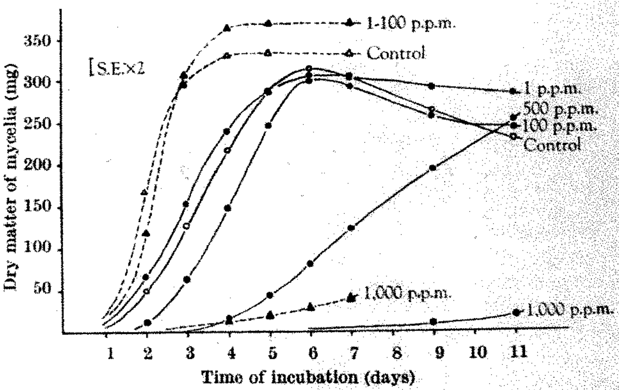

Fig. 3. Effect of coumarin on the growth of *P. glaucum* cultured on the synthetic nutrient medium and on yeast water with glucose. – – –, Yeast water + glucose; ——, mineral medium + glucose

It is striking that coumarin markedly stimulates the sporulation of *P. glaucum* grown on a synthetic medium. In series subjected to 1–10 p.p.m., spores were formed on the second day of cultivation and were green on the subsequent day. In the controls the spores appeared on the third day, but they were not green even on the fifth day of incubation. The case of *A. niger* was the same; on the third day of incubation the quantity of spores in sample 100 p.p.m. was nearly equal to control—in 100 p.p.m. they were black; in the control grey.

The most interesting results have been obtained with *R. nigricans*. This substance in concentrations 5–10 p.p.m. markedly stimulates the development of mycelia (Fig. 4). In affected series the mature spores were formed between 36–48 h, while in the control their appearance was noted in the fourth day of experiment.

Coumarin is metabolized by moulds. It was revealed by paper chromatography of ether and chloroform extracts of post-incubation media that during cultivation the spot of coumarin partially disappears, and new unidentified fluorescent spots occur. The velocity of synthesis of brown pigments, secreted to the medium by *A. niger*, is also retarded by coumarin. Thus it would seem that the process of autotoxication by products of mycelium metabolism is retarded by coumarin present in a nutrient medium in small quantities[7].

On the basis of these results it may be stated that: (*a*) coumarin is a fungistatic agent but not a fungitoxic one; (*b*) a physiological adaptation to this compound occurs. The nature of this adaptation still remains obscure because nothing is known about the primary mode of coumarin action[8]. Bearing in mind that moulds are much more sensitive to coumarin when they are cultured on the simple synthetic nutrient medium than on the yeast water, it can be assumed that this substance blocks the synthesis of an unknown metabolite (or metabolites) of fundamental importance to later stages of spore germination and

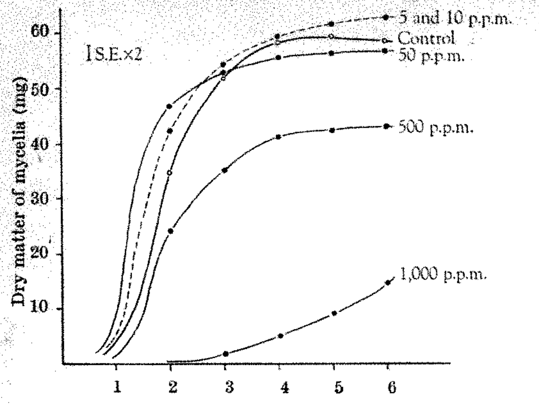

Fig. 4. Effect of coumarin on the growth of *R. nigricans* cultivated on the yeast water containing 4 per cent of glucose

initial growth of mycelia. This unknown metabolite is necessary either for nucleic acids and/or protein turnover, or for the utilization and storage of energy delivered in the breakdown of carbohydrates.

Coumarin does not directly affect the nucleic acid turnover in lettuce[9] and protein synthesis in sunflower[10]; however, it influences the spectrum of free amino-acids present in a cell, and some nucleic acid precursors partially reverse the coumarin-induced inhibition of growth of maize mesocotyle[10]. In connexion with the fact that coumarin affects the respiration[11] and phosphorus turnover in plants[12], these favour the supposition that coumarin controls the pathway of metabolism involved in the utilization of energy.

The stimulation of germination and growth caused by coumarin present in a medium in low concentrations may be elucidated on the basis of supposition that the affected cells react by the mechanism of super-compensation.

* *Addendum.* The Editor has directed my attention to a paper[13] describing the effects of some growth-regulators on the development of *Sclerotium rolfsii* (Sacc.), that is, the imperfect form of a basidiomycete attacking apple-trees. Coumarin in concentrations of 50–100 p.p.m. only slightly affects the growth-rate of mycelia (however, there is no growth at 500 p.p.m.); but it markedly inhibits the germination of sclerotia and reduces the number of progeny sclerotia per culture. Such sclerotia are darker in colour and larger than the normal ones; they germinate faster when planted on media without coumarin, but they are as sensitive to coumarin as control sclerotia are.

I thank Dr. Waclawa Maciejewska-Potapczyk for advice.

Non-climatic Factors affecting the Shape of Apple Fruits

SOME factors affecting fruit shape of apples are known. Partially seeded fruits are one-sided, the less fleshy side being adjacent to seedless carpels. Horticulturists have long observed that climate may also affect shape. Fruits grown in hot climates, especially where nights are warm, are flatter than those from cooler climates. In 1914, Shaw[1] stated: "There is a pretty constant fluctuation between the form of the apple and the temperature for a period following bloom; the cooler this period the more elongated the apple". In an effort to delimit this period, he concluded that the period from the sixth to the sixteenth days following full bloom fitted the observed fluctuations in form more closely than any other period. A recent study by Westwood[2], however, showed that very young fruits were distinctly elongated but became more flattened as they grew, the ultimate shape being determined about 100 days after full bloom. Thus, any effect of climate on shape might possibly extend well beyond a brief period after bloom.

Obviously, factors other than these affect shape because fruits from the same tree often differ strikingly. The investigation reported here was initiated to determine non-climatic factors which affect the shape of apples.

Test trees of Golden Delicious and three genetic strains of Delicious (Regular, Starking, Starkrimson) apples were grown under uniform cultural conditions at the Lewis-Brown Research Farm at Corvallis. All trees were 6–15 years of age. A minimum of pruning was done. The orchard received regular sprinkler irrigation during the season. The strains of Red Delicious were grown on several East Malling clonal rootstocks and on seedlings. A fruit-thinning test was carried out on matched leaders of 15-year-old Golden Delicious trees on East Malling IV rootstock. Heavy thinning was performed at full bloom on half the leaders. Only one flower in each eighth cluster was left, of which half were centre blooms and half were side blooms. Control leaders were not thinned. All trees in the thinning test had a uniformly heavy bloom (90 flower clusters per 100 growing points). For comparison, fruits from separate trees with light bloom (5 flower clusters per 100 growing points) were used.

Length/transverse diameter (*L*/*D*) ratio was used as an index of final fruit shape. The *L*/*D* ratio did not indicate subtle differences in shape but was adequate to distinguish between flat and elongated fruits.

Statistical differences (*L.S.D.* values) were calculated from error mean squares in a standard analysis of variance[3].

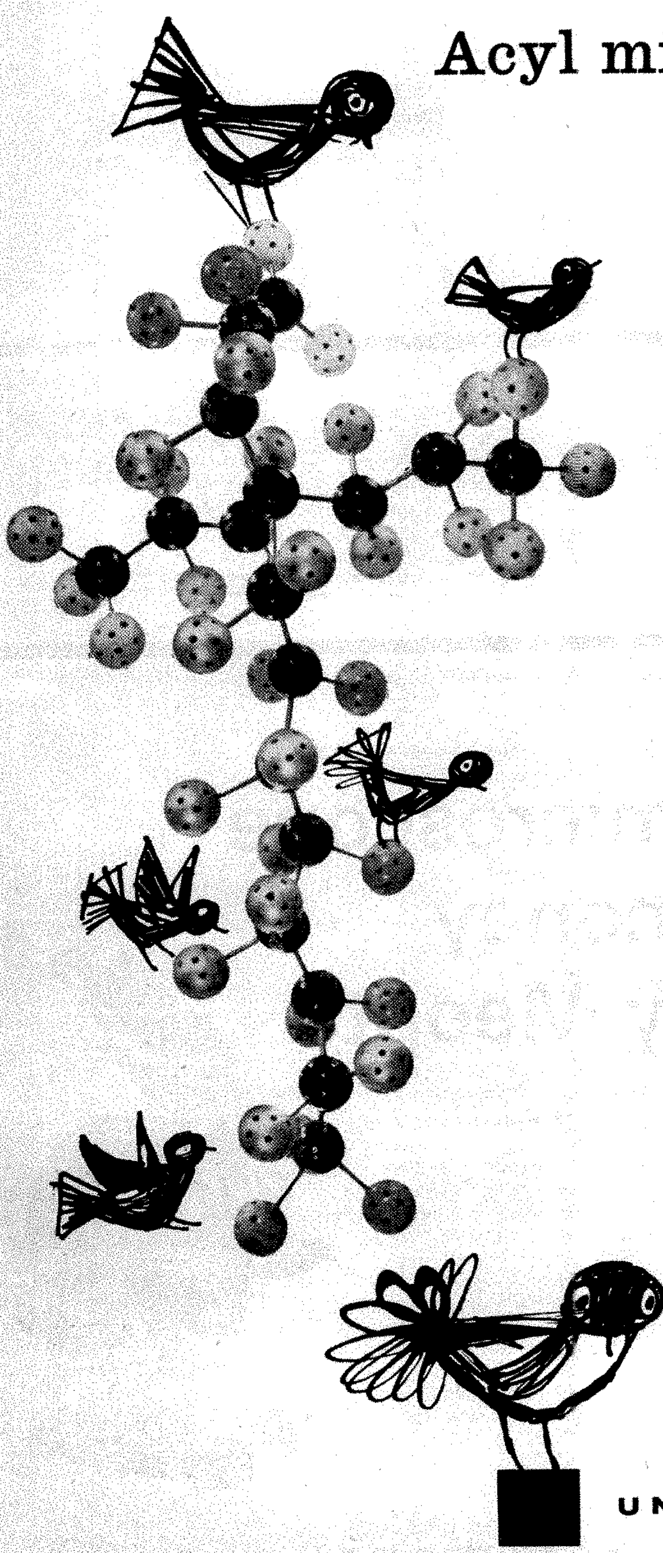
Rootstock type significantly influenced shoot growth and fruit shape of Red Delicious (Table 1). Fruits from trees with non-dwarfing rootstocks (seedling, XVI, I, II) were relatively more elongated than were those from dwarfing stocks (IV, VII, IX). Thus, relative fruit-length varied with rootstock in the same way as shoot growth. Shoot growth was shorter in every case on fruiting branches than on non-fruiting ones.

Table 1. EFFECT OF ROOTSTOCK ON FRUIT SHAPE AND SHOOT GROWTH OF RED DELICIOUS APPLE

Rootstock	Shoot growth Non-fruiting (cm)	Shoot growth Fruiting (cm)	Fruit* shape *L*/*D* ratio
EM XVI	46	39	0·967
Seedling	50	36	0·965
EM I	47	36	0·965
EM II	44	34	0·945
EM IV	31	15	0·938
EM VII	40	24	0·933
EM IX	24	9	0·920
L.S.D. 5% level			0·014

* 300 fruits measured from each rootstock.

Both crop density and cluster position affected the shape of Golden Delicious fruits (Table 2). Centre-bloom fruits were longer than side-bloom fruits, and light cropping (whether from heavy early thinning or from light bloom) resulted in longer fruits than did heavy cropping



Acyl migration

How welcome is the evocative word in the literature of science. Migration—geese in flight... swallows twittering on telephone wires... lemmings streaming blindly to sea. What of acyl migration? Alas, an element of bathos intrudes. At first we may see things in flight; but in truth, when we examine the concept, the vision changes to one of chimps swinging cheekily from branch to branch. Exactly so with partial glycerides: identifiably so with tri-glycerides, but the behaviour pattern is a little more complicated!

That acyl groups in glycerides can migrate remains a matter of surprise—even though rearrangement in fatty esters was first reported by Claisen so long ago as 1887, and in diglycerides by Fischer in 1920. Delayed interest in the subject has been due largely to the absence of good analytical methods, but the recent spate—differential thermal analysis, infra red spectrometry, partition chromatography, enzymic splitting, radio tracers—has opened the field, and today we are beginning to understand the mechanisms whereby an acyl group can swing between the 1- and 2- position in a partial glyceride, and interchange between triglycerides.

Work on acyl migration is of theoretical importance in the understanding and control of these mechanisms, and of practical importance both in the preparation of model substances for systematic study, and in the large scale treatment of oils and fats to modify their physical behaviour.

Unilever Research is working to gain this understanding and control.

UNILEVER RESEARCH

UR22-7049-85

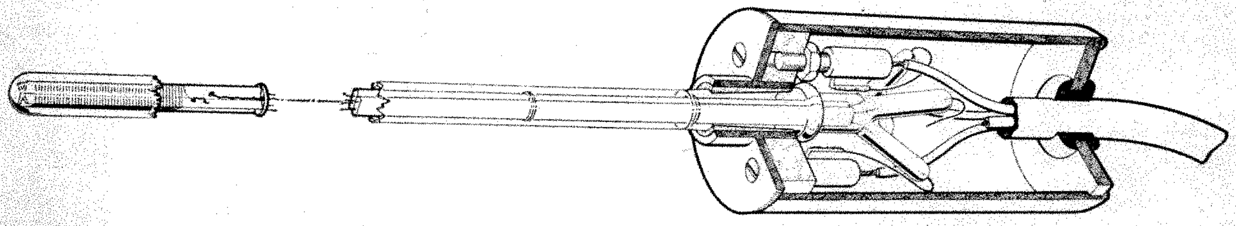
REPRODUCIBILITY BETTER THAN 0.001°C OVER RANGE −200° TO +700°C

The Cambridge Precision Resistance Thermometer (potential lead type) has a reproducibility of better than 0.001°C. Great care is taken during manufacture to ensure that the platinum element is uncontaminated and free from strain. Specification is as follows:

Ranges:	− 200°C to + 500°C (with Pyrex glass sheath): up to 700°C (with quartz glass sheath).
Fundamental interval:	10 ohms (nominal)
Ice resistance (R_0):	25 ohms ± 0.1 ohms.
Reproducibility:	better than 0.001°C.
Self-heating effect:	approximately equivalent to 0.0003°C at 1 mA.
Internal atmosphere:	10% oxygen, 90% helium at approximately ½ atmos.
Lag constant:	of the order of 8-9 seconds.

METHOD

We recommend that the Cambridge Precision Resistance Thermometer is used either with a Cambridge Smith's Difference Bridge or with a Cambridge Microstep Precision Potentiometer with resistance standard, etc. Write for full details.



Write for List A36N. For future publications, ask for Mailing Form N/11/63.

Cambridge PRECISION RESISTANCE THERMOMETER

Cambridge Instrument Company Limited, 13 Grosvenor Place, London, S.W.1

You get more microscope for your money when you buy Meopta

Meopta microscopes surprise even the experts. They're such finely made precision instruments but cost so much less than you'd expect. Every Meopta microscope is designed to meet the highest optical standards—Meopta objectives are especially noted for superlative quality. Yet you pay less for a Meopta than for any comparable instrument. It's not surprising that so many far-sighted scientists have already chosen Meopta microscopes for their teaching and research laboratories.

Microscope C36 BI

Meets all the requirements of scientific and research workers. Binocular microscope with built-in mechanical stage, integral Kohler lighting and photomicrography tube. Standard optical equipment includes six achromatic objectives, three pairs of eyepieces and a N.A. 1.4 condenser. Magnifications from 43x to 1.800x

Table 2. EFFECT OF FRUIT POSITION AND DEGREE OF THINNING ON THE SHAPE AND SIZE OF GOLDEN DELICIOUS FRUITS

Amount of thinning	Amount of bloom	Cluster position	No. of fruits	Fruit weight (g)	Fruit shape *L/D* ratio
Heavy (full bloom)	heavy	centre	80	236	0·987
	heavy	side	80	218	0·954
None	heavy	centre	80	174	0·960
	heavy	side	80	151	0·920
Light (late)	heavy	—	80	170	0·935
None	light	—	80	207	0·960
L.S.D. 5% level					0·013

leaders or trees. Fruit size *per se* did not correlate well with shape.

Centre-bloom fruits of Red and Golden Delicious were longer than side-bloom fruits both when grown on separate or on the same spur cluster (Table 3). Variability was less, and the difference was more striking when centre- and side-bloom fruits were paired on the same cluster. This would be expected because such factors as leaf/fruit ratio and spur vigour were identical for each pair.

Table 3. EFFECT OF FRUIT POSITION ON THE SHAPE OF APPLE FRUITS GROWN ON THE SAME OR SEPARATE CLUSTERS

Variety and fruit position	No. of fruits	Fruit shape *L/D* ratio	*L.S.D.* 5% level
Golden Delicious :			
Separate cluster—centre	350	0·942	0·017
Separate cluster—side	350	0·911	
Red Delicious :			
Separate cluster—centre	350	0·922	0·014
Separate cluster—side	350	0·897	
Same cluster*—centre	17	0·891	0·011
Same cluster —side	17	0·854	

* Each cluster contained one centre- and one side-blossom fruit.

Fruit shape of three genetic strains of Red Delicious was significantly different (Table 4). Common Red Delicious fruits were markedly flatter than Starkrimson or Starking fruits.

Table 4. FRUIT SHAPE AS RELATED TO THREE GENETIC STRAINS OF RED DELICIOUS APPLE GROWN ON NON-DWARFING ROOTSTOCKS*

Strain	No. of fruits	Fruit shape *L/D* ratio
Common Red Delicious	200	0·903
Starking Delicious	100	0·932
Starkrimson Delicious	200	0·980
L.S.D. 5% level		0·016

* Grown on seedling or *EM* XVI rootstocks.

The fleshy part of the apple, a pome fruit, is non-ovarian tissue, being considered either a proliferation of the stem[4], or a fusion of floral parts[5]. In any event, it is derived from vegetative tissue. The inflorescence is determinate with usually 5 or 6 flowers, one of which, the centre-bloom, terminates the axis. Thus the centre-bloom fruit has a position analogous to that of a primary shoot arising from a terminal bud ; a side-bloom fruit is analogous to a shoot arising from a lateral bud. The lengths of terminal and lateral shoots of Starking Delicious (not shown in tables) were found to be 65 cm and 46 cm, respectively. Visual inspection showed terminal shoots to be longer than lateral shoots in the other varieties also. The same length relationship holds for centre- and side-fruits (Tables 2 and 3). Non-cropping branches produce longer shoots than heavy-cropping ones irrespective of rootstock (Table 1). The trend also (Table 1) is for the fruits to become shorter as the shoots on fruiting branches become shorter.

The results presented show that differences in shoot length resulting from rootstocks, crop density, or shoot position vary in the same way as do comparable fruits from the same trees. This close parallel of fruit and shoot length suggests a close physiological relationship in the two organs which continues to persist even perhaps after an extensive evolutionary development of the fruit from vegetative tissue. Since cell elongation is mediated by auxin, we suggest that the factors which affect fruit shape do so by regulating the auxin available to them. The existence of local differences in auxin, which result in such phenomena as apical dominance, while generally accepted, are not well understood.

An apparent inconsistency exists with the mutant strain Starkrimson, which has longer fruits (Table 4) than the standard strains, but the shoots of which are noticeably shorter. This anomaly, however, appears to be a part of the built-in genetic difference between strains, because the relationship between fruit and shoot length (as related to rootstocks and position) held for Starkrimson as for other strains of Delicious. The supporting data for Starkrimson are not given, because they essentially duplicate the data of Tables 1 and 3.

It is evident that several factors besides climate can affect shape of the apple. These studies were done in a relatively cool temperate marine climate, and it is not known whether the same relationships would be found in a climate conducive to very flat-shaped fruit. The effect of climate on shape of fruit may be more important than the factors examined here, but our results suggest several ways one might alter shape of fruit within a given climate, if it were commercially advantageous to do so. In the past, buyers have favoured the long conical-shaped Red Delicious over the round or flat ones. Tests are being made to determine the effects of different climatic variables on shape of apple fruits.

Starch-gel Electrophoresis of Proteins as an Aid in Identifying Fungi

MANY species of fungi are difficult to identify, particularly if they lack reproductive structures. Even if reproductive bodies are developed, the extent to which their morphological features, such as shape, size and colour, can be used as taxonomic criteria is often controversial. Species of *Pythium* are not easily characterized by conventional morphological criteria. This paper describes the application of starch gel electrophoresis of mycelial proteins to the identification of *Pythium* species.

Electrophoretic patterns of proteins in plasma and in eggs have been used as guides in the taxonomy of many animal species[1-3], and Chang, Srb and Steward[4] have recently shown marked differences between protein patterns obtained from different *Neurospora* species and smaller but significant differences between patterns obtained from strains of *N. crassa*.

In the work described here cultures of *Pythium* species were grown in liquid Czapek–Dox medium supplemented with 0·1 per cent yeast extract and incubated at 25° C on a rotary culture shaker. Mycelium was collected by filtration after 5, 8 and 10 days, washed with distilled water, frozen and broken in a Hughes press[5]. The suspensions of broken mycelium were mixed with one-tenth of their volume of buffer (0·76 M *tris*-citrate containing 5 mM ethylenediamine tetraacetic acid, *p*H 8·5) and centrifuged at 130,000*g* for 45 min. As little as 1 g of fresh mycelium could be used in 5 ml. centrifuge tubes (Spinco *SW* 39*L* rotor), but in this case paraffin oil was added to the centrifuge tubes to make up the required volume. The supernatant liquids and mycelia were stored at −15° C without deterioration. Samples (about 0·05 ml.) of supernatant were applied to pieces of Whatman 3*MM* paper (5 × 8 mm) and these were inserted in slots in 12 per cent starch gel in 0·076 M *tris*-citrate containing 0·5 mM EDTA, *p*H 8·5. Gels were 10 cm wide, 15 cm long and 0·5 cm thick and were used horizontally. Electrophoresis was carried out at about 5 V/cm and the gels were cooled by resting containers of crushed ice on them. Poulik's[6] discontinuous borate–citrate buffer system (0·3 M sodium borate, *p*H 8·5 in the electrode vessels) was used; resolution of components with this system is better than in continuous buffers. Protein components were detected by staining with amido-black 10*B* as described by Smithies[1].

Fig. 1 shows patterns obtained with six *Pythium* species. The patterns are easily distinguishable and have only one band in common. Samples of the same species isolated from different localities were either indistinguishable or showed only minor differences (Fig. 2). Samples of any one culture harvested at three different ages showed identical electrophoretic patterns of their proteins.

Similar experiments with *Pullaria pullulans*, *Fusarium oxysporum* var. *pisi* (races 1 and 2), bakers' yeast and other Ascomycetes showed that protein patterns of *Pythium* species differ as much from one another as they do from the protein patterns of these representatives of other fungal groups.

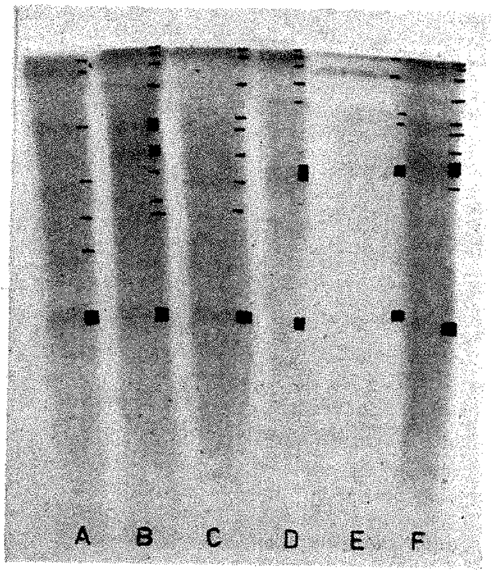

Fig. 1. Patterns obtained from mycelial extracts of six *Pythium* spp. (*A*) *P. echinulatum*; (*B*) *P. debaryanum*; (*C*) *P. irregulare*; (*D*) *P. ultimum*; (*E*) *P. dissimile* (Vaartaja sp. nov. ined.); (*F*) *P. violæ*

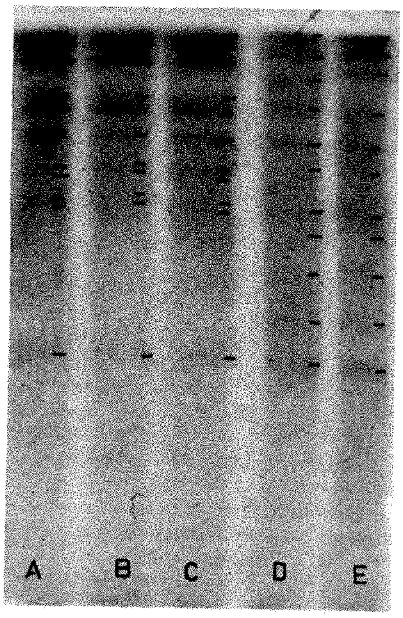

Fig. 2. Extracts from isolates of any one species collected at different localities gave similar patterns. Patterns (*A*)–(*C*) were obtained from different isolates of *Pythium intermedium* and (*D*)–(*E*) from different isolates of *P. myriotylum*

It seems likely that patterns of this sort will be useful aids in the delimitation of fungal species.

I thank Dr. M. R. Atkinson, of the Department of Agricultural Chemistry, for suggesting this approach to the problem and for advice on analytical methods, and Dr. L. O. Vaartaja for supplying cultures of *Pythium* species.

MICROBIOLOGY

Bacteriophages Specific for some *Mycobacteria*

MYCOBACTERIOPHAGES are generally known to lack specificity. However, due to chance isolation or to selection by enrichment with certain types of *Mycobacteria*, isolation of bacteriophages specific for *Mycobacterium phlei*, *M. pellegrini* and *M. tuberculosis* var. *hominis* and *bovis* was reported.

In the course of screening earth samples from Lausanne soil for the presence of mycobacteriophages (Hauduroy and Tanner, 1962), bacteriophages lysing mycobacteria were found in the majority of filtrates prepared according to the procedure described by Froman *et al.*[1]: In each case the earth samples were incubated at 37° C, enriched periodically by 13 rapid growing mycobacterial strains, centrifuged at 3,000 r.p.m. for 30 min and the supernatant filtered through a Chamberland *L*3 filter. The presence of bacteriophages lytic for mycobacteria was detected by the agar layer technique of Gratia as modified by Froman *et al.*[1]. 4 out of 16 bacteriophages thus obtained were of special interest:

(1) Filtrate No. 5 was found specific for *M. rubrum* (*F* 180, Froman, Los Angeles) from the beginning of its isolation. (2) Filtrate No. 7, initially active against *M. rubrum* (*F* 180), *M. smegmatis*, *A.T.C.C.* 607 (*F* 21, Froman, Los Angeles) and *M. fortuitum* (*F* 3816, Froman, Los Angeles), lost its capacity to lyse *M. smegmatis* (*F* 21) and *M. fortuitum* (*F* 3816) after 5 serial transfers on *M. rubrum* (*F* 180), and behaved afterwards as a specific bacteriophage for *M. rubrum* (*F* 180). (3) Filtrate No. 10 showed in the beginning a lytic activity for both the strains *M. smegmatis* (*F* 21) and *M. phlei* (*F* 89, Froman, Los Angeles). However, it lost its lytic activity for *M. smegmatis* (*F* 21) on 5 serial transfers on *M. phlei* (*F* 89) and *vice versa*: no lysis of *M. phlei* (*F* 89) was detectable after 5 serial passages on *M. smegmatis* (*F* 21).

Thus, in the case of filtrate No. 7, a specific phage against *M. rubrum* (*F* 180), and in the case of filtrate No. 10 two specific phages, one against *M. smegmatis*, the other against *M. phlei* (*F* 89), were obtained. It is suggested that in both cases this was due to 'adaptation' of a bacteriophage to specific host strains, although the probability of the coexistence of two distinct bacteriophages in filtrate No. 10 cannot as yet be excluded.

The 4 mycobacteriophages—differing with regard to the origin of their specificity—were tested against a variety of mycobacterial species. These included various strains of 'same' species, that is, strains received from different laboratories but having in common that they were designated as either *M. phlei* or *M. smegmatis*. As can be seen from Table 1, the bacteriophage active against *M. phlei* (*F* 89) lysed 5 out of 8 strains of *M. phlei*, that is, 4 strains in addition to the homologous host strain *F* 89. The

Table 1

Name of species	No. of strains	Lytic activity of Phage *phlei F* 89	Phage *smegmatis F* 21	Phage *rubrum F* 180 No. 5	No. 7
Mycobacterium phlei	8	5	0	0	0
M. rubrum	1	0	0	1	1
M. smegmatis A.T.C.C.607	3	0	1 (*F* 21)	0	0
M. smegmatis	12	0	0	0	0
Various rapid-growing mycobacteria	14	0	0	0	0

bacteriophage active against *M. smegmatis*, on the other hand, did not lyse but the homologous host strain F 21 did.

The confusion existing at present in the classification of mycobacteria : the arbitrary grouping of several strains, the frequent changes of species designation, the circulation of Collection strains with obscure past histories, makes it difficult to decide if the lysis of several mycobacterial strains by the same bacteriophage can be considered as a sign of their close relationship (sub-groups of same species), or only shows the common derivation (sub-cultures) of the strains tested, while those strains non-lysable by the specific bacteriophage bear the name of the species without any justification.

Nevertheless, this investigation shows the theoretical possibility of obtaining specific lytic activity against distinct groups of mycobacteria by serial passages from initially polyvalent filtrates.

I thank Prof. Paul Hauduroy for the initiation of this research project, for advice and for the facilities provided while I was guest in his Institute.

Water-soluble Products of Methyl Cholanthrene and Their Effect on Bacterial Growth

THE production of tumour cells in certain mammalian systems by carcinogenic agents stimulated considerable interest in testing the effects of these compounds on other kinds of cells. Micro-organisms, because of their apparently simpler structure and their adaptability to growth under controlled cultural conditions, have been repeatedly used in such assays. For different bacteria, yeasts, or moulds carcinogens have been reported : (*a*) to produce large and sometimes abnormal cells[1] ; (*b*) to inhibit early phases in the growth curve[2] ; (*c*) to increase the total number of cells in cultures[3] ; (*d*) to be involved in photodynamic lethal effects[4] ; (*e*) to induce mutations[5].

Results described in these assay tests are not always reproducible, and even now little can be said, other than to quote the literature concerning definite effects of carcinogens on bacterial and fungus cells. The method of administering the carcinogen (usually methyl cholanthrene, benzpyrene, or 1,2,5,6-dibenzanthracene) may be one main cause of the variability or indefinite results obtained. These compounds are not soluble in water and the usual method of their application has been either : (*a*) to grind the crystals in water, making a finely divided suspension which is incorporated into a culture medium (agar or broth) ; (*b*) to filter similar suspensions after considerable periods of time, resulting in so-called 'saturated solutions' which are then used as the basis for an agar or a broth ; (*c*) to add the carcinogen to the medium in solution in some organic solvent (as acetone or alcohol), later evaporating the solvent by heating or during the sterilization process. This communication describes a method to circumvent this difficult problem by selecting an assay organism (*Bacterium aliphaticum*) which can utilize hydrocarbons such as pentane, heptane, or other paraffins as the sole carbon source[6]. Since the carcinogens are themselves hydrocarbons exposure can be achieved with the carcinogen in solution in the bacterium's normal food. There is greater assurance in this case that the carcinogen will come in contact with the micro-organism; further, metabolic and biologic observations are quite easily made.

Cultures were prepared in test-tube-like cuvettes preselected for uniformity for use in fluorimetric analysis. After filtration through No. 1 Whatman filter paper 10 ml. Tausz's solution (MgNH$_4$PO$_4$, 1·0 g ; KH$_2$PO$_4$, 0·8 g ; CaSO$_4$, 0·1 g ; FeCl$_3$, trace ; KI, trace ; distilled water, 1,000 ml.) was placed in each tube and sterilized for 20 min at 15 lb. pressure. Inoculations (2 drops per tube) were made with sterile pipettes from cultures previously grown one week in Tausz's solution with paraffin oil as the sole carbon source. Sterile paraffin oil (2 ml.) was then added, forming an oil layer over the basal medium ; this layer contained the desired amounts of methyl cholanthrene in carcinogen-treated cases. Cultures were maintained at 28° ± 2° C in incubators or in a diffusely lighted room.

Dilution plate analyses using nutrient agar were made to assay the number of organisms present at various periods of time (up to 10 years) in cultures of the kind described. Methyl cholanthrene, in all concentrations, placed in the oil layer (62·5–500 μg/ml.) adversely affected both the population-size and long-term viability of the cultures. After 2 years the population-sizes of the methyl cholanthrene-treated cultures were usually less than half those of the controls. With only an occasional exception, all carcinogen-treated cultures examined between 2 and 10 years of age showed smaller populations than controls.

The smaller population size indicated toxicity leading to death of cells in tubes containing carcinogen, a suggestion further supported by the data which show expiration of the cultures from time to time (Table 1). The data are based on 300 methyl cholanthrene-treated cultures (50 replicates each of six concentrations of methyl cholanthrene 62·5–500 μg/ml. added in the paraffin oil) and 300 cultures without carcinogen as controls. After 4 years, cultures containing carcinogen were 47 per cent expired; there were no losses among controls. After 7 and 10 years respectively, cultures containing carcinogen were 70 and 100 per cent expired compared with 7 and 15 per cent among controls. Further, cultures containing the heaviest concentrations of carcinogen (250–500 μg/ml.) began to die out first. With the exception of complete kill obtained at a concentration of 250 μg/ml. after 7 years, the per cent of kill at any given age was roughly proportional to the concentration of added methyl cholanthrene.

Table 1. EFFECT OF METHYL CHOLANTHRENE ON VIABILITY OF *Bacterium aliphaticum*

Supplement to medium	No. of cultures	No. of cultures surviving after : 2 yr.	4 yr.	7 yr.	10 yr.
Methyl cholanthrene	300	290	140	90	0
None (controls)	300	300	300	280	255

Under certain conditions fluorescence measurements can be used to follow changes in the concentration of methyl cholanthrene and structurally related compounds. The water layer of the cultures established was not fluorescent at zero time. Surprisingly, fluorescence developed in this layer, increasing rapidly and linearly for the first ten weeks, and also increasing thereafter, but at a lesser rate. The fluorescence was similar to that of methyl cholanthrene and absent in controls without carcinogen. This suggested that water-soluble products of methyl cholanthrene were formed within a relatively short period of time. An appreciable concentration of these products develops spontaneously in diffuse light, and more rapidly under ultra-violet than with visible light. However, cultures containing *B. aliphaticum* develop much greater fluorescence at any age than appropriate spontaneous controls (no organism). Fluorescence measurements on the water layer before and after the cells were removed by centrifugation indicated that most of the fluorescence originated in the culture fluid; the contribution of the cells to the total was relatively small.

The fluorescent material in the water layer was chromatographed on paper with chloroform–water mixtures, yielding a definite spot moving slightly behind the front. The substance is not methyl cholanthrene, as this compound remains in the original spot and does not advance in the solvents used. The material is noticeably fluorescent on the paper. Its chemical nature has not been further established. However, both the water layer itself and the chromatographically isolated fluorescent spots proved weakly toxic to *Bacillus subtilis* and *Staphylococcus aureus*. Small inhibition zones (disappearing after 48 h) developed when 1 ml. of the water layer from methyl cholanthrene-treated cultures was used in the cup in place of penicillin following standard penicillin cup assay procedures[7]. Similar weak inhibition zones were noted when fluorescent filter paper disks from the chromatograms were placed on seeded nutrient agar plates.

It seems logical to associate this weak toxicity with the small populations and long-term loss of viability of the cultures containing carcinogen. Further, these results suggest that water-soluble oxidation products may be directly involved in this toxic effect. The existence of these substances also raises the question as to what extent such effects as death, cell enlargement, mutagenicity, etc., reported by other workers[1-5] and usually attributed to methyl cholanthrene (or other carcinogens) in the existing literature, might be due to reaction products of the carcinogen rather than to the compound itself.

This work was supported in part by a grant-in-aid from the American Cancer Society.

Evaluation of Colorimetric Methods in the Estimation of Sialic Acid in Bacteria

NUMEROUS reports have appeared claiming the presence of the sialic acids in various Gram-negative bacteria[1-9]. In several communications[7-9] the detection and estimation of these acids were made solely by the colorimetric procedure of Warren[10]. In others, a modified direct Ehrlich procedure was used[1-5].

The estimation of sialic acid by Warren's procedure involves several steps. These include hydrolysis to release the sialic acid, periodate oxidation of the acid to β-formyl pyruvate, reduction of excess periodate with sodium arsenite, addition of thiobarbituric acid followed by extraction of the chromogen with an absorption maximum of 549 mμ into *cyclo*hexanone. In addition to the sialic acids, 2-keto-3-deoxyoctonate is present in certain bacteria[11] and yields β-formyl pyruvate on periodate oxidation. Thus, as no method is available to determine the origin of β-formyl pyruvate, a positive result by the Warren assay may not necessarily indicate that sialic acid was present. The Warren method is further complicated by the existence of 2-deoxyribose and the 3,6-dideoxyaldohexoses in bacteria. On periodate oxidation these substances yield malonaldehyde which forms a chromogen with thiobarbituric acid with an absorption maximum at 532 mμ and considerable absorption at 549 mμ. This chromogen may be removed by extraction with isoamyl alcohol[10] prior to the *cyclo*hexanone extraction. An alternate procedure has been devised[10] to correct for absorbance due to the malonaldehyde-thiobarbituric acid chromogen in mixtures of the two chromogens.

In contrast, the estimation of sialic acid by the modified direct Ehrlich method is simple. It involves heating the cells in a solution containing mineral acid, aluminium sulphate and dimethylaminobenzaldehyde. The pyrrole derivative formed from degradation of sialic acid is immediately trapped by the dimethylaminobenzaldehyde and gives a chromogen with an absorption maximum at 530 mμ. In view of the popular usage of the thiobarbituric acid procedure for detection and estimation of the sialic acids, it was of interest to compare the results obtained by using the direct Ehrlich and Warren procedures on Gram-negative bacteria grown under similar conditions.

All enteric bacteria were grown in 1 l. of sterile nutrient broth containing 30 ml. of 50 per cent dextrose and 7 ml. of the filtered, sterile and concentrated dialysate obtained from 5 g of Difco yeast extract. Each culture, seeded with 0·2 ml. of a 3 ml. slope wash of an overnight culture, was grown for 6 h at 37° C with æration. *Rhodopseudomonas palustris* was grown at 25° C for 48 h without æration and under illumination by a 200-W tungsten lamp placed 6 in. from the flask. The bacteria were killed with chloroform and collected by centrifugation. The cells, after washing and recentrifugation, were suspended in water and lyophilized. A recovery of 70–400 mg of material was obtained. The *Veillonella* cells were kindly given by Dr. S. Mergenhagen of the National Institutes of Health, Bethesda, Maryland.

Analyses for sialic acid were performed on 30–100 mg of dried cells by a modified direct Ehrlich procedure[5] and on the clarified supernatant of cell hydrolysates by Warren's method[10]. An examination was first undertaken to determine the conditions of hydrolysis for maximum release of sialic acid. The results, obtained by using *Salmonella ngozi*, are given in Fig. 1. It can be seen that maximum amounts of sialic acid are released by heating in 0·1 or 0·5 N sulphuric acid at 100° C for 60 min and in 1·0 N acid for 20 min. Hydrolysates were, therefore, routinely prepared by heating 10 mg of dried cells for 20 min at

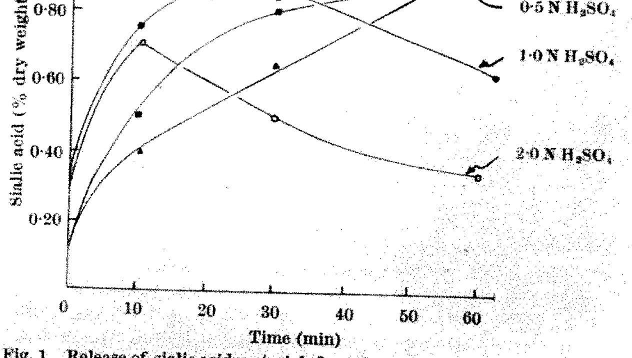

Fig. 1. Release of sialic acid materials from *Salmonella ngozi* in sulphuric acid at 100° C

100° C in 1 ml. of 1·0 N acid followed by centrifugation. The percentage of sialic acid was calculated using reference curves in which ovine sialic acid (*N*-acetylneuraminic acid) served as standard.

The per cent sialic acid content of the bacteria analysed is recorded in Table 1. The determinations made by the thiobarbituric acid method are recorded as uncorrected and corrected values obtained after extraction of the malonaldehyde-thiobarbituric acid chromogen with isoamyl alcohol. It is to be noted that for all the bacteria which give a positive Ehrlich test, the assay for sialic acid determined by this procedure is greater than that obtained by the thiobarbituric acid assay. As the latter method measures free and terminally bound sialic acid, it would appear that some of the acid is either destroyed during hydrolysis or remains attached to the cell debris. Although temperature, time or normality of the acid were varied in the preparation of the hydrolysates, the values for sialic acid obtained by the thiobarbituric acid procedure when using isoamyl alcohol extraction never equalled the higher values found by the direct Ehrlich method. A similar result was obtained when absorption measurements were made at various wave-lengths on the mixture of chromogens and calculations made for sialic acid by the alternate procedure of Warren[10].

Several bacteria listed do not appear to contain sialic acid as determined by the Ehrlich assay, but have an 'apparent' content of sialic acid[8,9] when analysed by Warren's method. Paper partition chromatographic analyses of hydrolysates of these bacteria failed to show sialic acid, whereas in hydrolysates of strains which give positive Ehrlich and Warren assays, such as *Arizona*, *Salmonella* and *Citrobacter freundii*, the acid is readily detectable. Moreover, the presence of ovine sialic acid was definitely established in the *Citrobacter freundii* strain by isolation[12,13]. Thus, it is strongly indicated that sialic acid is present in bacteria which give a positive Ehrlich test but not in those which only give a positive Warren test. The chemical nature of the substances in bacteria which give a positive Warren and negative Ehrlich assay is unknown. However, in the case of *E. coli* 0111 : $K58(B4)$: HNM, which contains colitose (3,6-dideoxy-L-galactose) and 2-keto-3-deoxyoctonate, the positive result obtained in the thiobarbituric acid assay may be due to the latter substance.

It is concluded that Warren's method for estimation of the sialic acids in micro-organisms gives lower values than are obtained by the direct Ehrlich procedure. Although the thiobarbituric acid assay is some 80-fold more sensitive than the modified direct Ehrlich, it is also less specific. The results clearly reveal that sialic acid is present in *Arizona* 029, *Arizona* 05 and *Salmonella* 048 serotypes. Moreover, it is of interest to mention that *Salmonella* 048, *Arizona* 029 and *Citrobacter freundii* 05 are serologically related to *Arizona* 05 (refs. 5 and 14). As sialic acid is absent in other *Salmonella* O serotypes and has not been detected in other *Arizona* O serotypes, it is suggested that the chemical basis for the serological relationships among these strains involves sialic acid.

We thank Dr. S. Aaronson, of the Haskins Laboratories, Inc., New York, for the *Serratia marcescens*, *Pseudomonas vulgaris*, *Rhodopseudomonas palustris*, *Aerobacter aerogenes* and *Escherichia coli* N.D. strains, and Dr. W. H. Ewing of the Communicable Disease Center, Atlanta, Georgia, for the *Arizona*, *Salmonella* and other *E. coli* strains. CYTOLOGY

In vivo Incorporation of Tritiated Thymidine in Acute Leukæmia Chromosomes

THE DNA metabolism of normal human blood cells has recently been investigated at chromosome-level by means of an autoradiographic technique and 2–4 day *in vitro* culture of peripheral leucocytes[1–3]. The application of this type of investigation to the study of human leukæmia cells was prompted by recent reports of abnormal chromosome number and/or shape in these cells[4–6].

Three points must be borne in mind in undertaking such an investigation. First, account must be taken not only of circulating blood cells but also of bone marrow elements. Secondly, long-term cultures should be avoided in view of the discrepancies in the chromosome complement recently observed between *in vitro* data and direct *in vivo* observation (false-negative results)[7]. Thirdly, additional information could be expected by improving the resolution and efficiency of the method.

With this in mind, the *in vivo* incorporation of tritiated thymidine into the chromosomes of a patient with acute leukæmia was investigated. The patient was a male with untreated acute myeloblastic leukæmia : 76 per cent of the bone marrow cells and 91 per cent of the circulating leucocytes were myeloblasts and paramyeloblasts ; the peripheral white cell count was 72,000/mm³. With regard to the chromosome complement, 60 per cent of the cells had 46 chromosomes (modal number), the remainder 45, 47, 48 and 49 chromosomes. No chromosome marker was found ; the extra chromosomes belonged, in most cases, to groups 13–15 and 16–18 ; a few could be included in group 19–20. Ten mc. of tritiated thymidine (s.a. 1·4 c./m.mole) was injected intravenously. It is known that a single administration of thymidine *in vivo* serves the purpose of pulse-labelling[8]. The autoradiographic and chromosome technique used in the investigation recorded here has been reported in detail elsewhere[9]. The cells to be examined were obtained by sternal puncture performed 105 min after the administration of thymidine and 60 min after *in vivo* colchicine blocking[10,11].

50·6 per cent of the mitotic figures (out of a total count of 420 mitoses) showed evidence of labelling: owing to the experimental conditions, tagged mitotic figures could only be found in the cells which had incorporated the precursor in the final stages of the synthetic period, whereas the unlabelled figures correspond to cells which were past the *S* stage at the time of labelling.

For this investigation we selected a total of 30 labelled mitotic figures with a clearly outlined morphological pattern and with a total grain count ranging from 80 to 350 (Fig. 1). The chromosome number was 46 in 18 mitoses and more than 46 in 12. Karyotypes were arranged according to the Denver classification: when the intensity of labelling precluded identification of the chromosomes, the nuclear emulsion on the slides was removed after photographing the mitotic figures and localizing and counting the grains[9].

The rate of precursor incorporation was established by counting the grains on the chromosomes and on their arbitrarily chosen segments: a 'specific incorporation rate' was calculated by relating the number of grains to the relative length of the chromosomes or chromosome segments, as recently proposed[3]. Owing to the small number of mitotic figures featured in this preliminary experiment, the incorporation rate was calculated for chromosome groups rather than pairs where the chromosomes of neighbouring pairs were interchangeable. The 'specific incorporation rate' was consequently calculated for the following pairs or groups of chromosomes: 1,2,3, 4,5, *X*–6–12, 13–15, 16,17,18, 19–20, 21–22, *Y*. When the individual extra-chromosomes could not be identified with sufficient accuracy, they were included in the pairs or groups to which they were morphologically related. Finally, the 'specific incorporation rate' was calculated for each of the segments of the various chromosome pairs or groups.

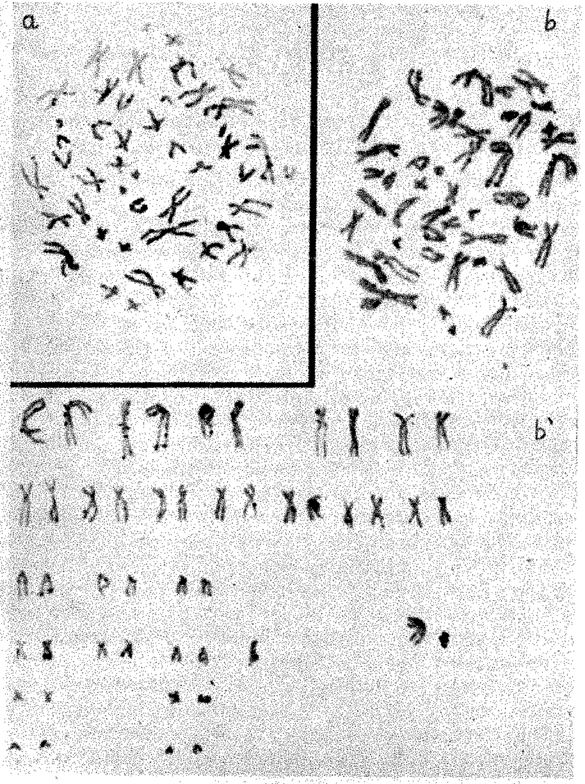

Fig. 1. *a*, labelled mitotic figure of bone-marrow cell with 46 chromosomes; *b*, labelled mitotic figure of bone-marrow cell with 47 chromosomes; *b*¹, karyotype of *b*

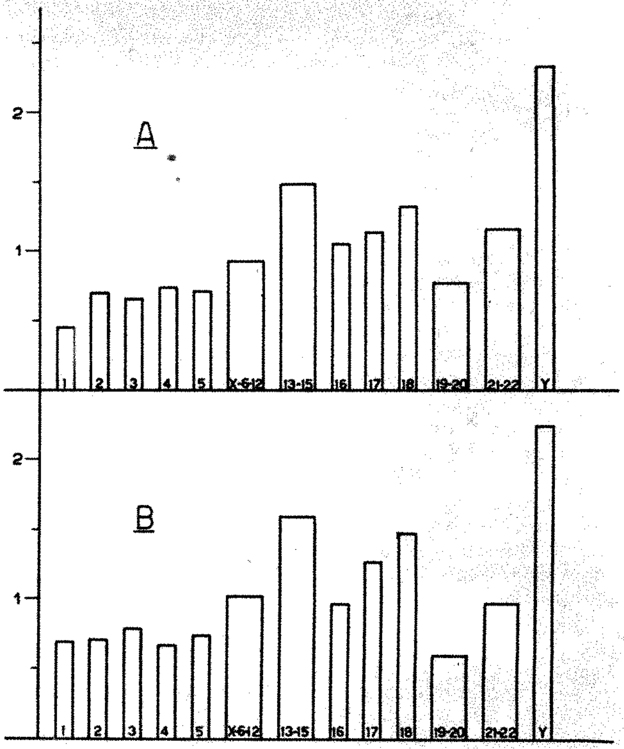

Fig. 2. 'Specific incorporation' (ordinate) of tritiated thymidine (pairs and groups of chromosomes)
A, euploid mitoses; *B*, aneuploid mitoses

Fig. 2 shows the mean values for each pair or group; the values of euploid and aneuploid mitoses are reported separately. The two types of mitoses (euploid and aneuploid) displayed similar behaviour, and significant differences could not be demonstrated between the corresponding pairs or groups of chromosomes. On the contrary, both in euploid and aneuploid mitoses a significant degree of variation was observed among the different pairs or groups of the same mitotic figures and considerable differences could also be demonstrated between the segments making up the various pairs or groups of chromosomes. All these differences in the 'specific incorporation rate' could be confirmed statistically by means of variance analysis. The highest incorporation rates were found in the chromosomes of group 13–15 and pairs 17 and 18, the lowest in the first pairs and in group 19–20. In the segments no constant pattern could be demonstrated: there was a higher incorporation rate in the segments close to the centromere in pairs 1 and 3, in the distal segments of the long arms of pairs 16 and 17, in the short arms of pair 2 and in the distal segments of the chromosomes of group 19–20. Both in euploid and aneuploid mitoses the incorporation rate in the chromosome *Y* was higher than in any of the autosomes.

A comparison was also made between the incorporation rate of the extrachromosomes and the corresponding autosomes, and between the incorporation rate in the pairs or groups in which extra chromosomes had been included and the corresponding pairs or groups with no extra-chromosomes. A higher incorporation rate was noted in the extra-chromosomes; however, this finding requires confirmation, and further investigations are under way on this point.

From the foregoing preliminary findings certain conclusions can be drawn. (1) Duplication of DNA follows not a random course but a particular time sequence not only in normal blood cells[3] but also in acute leukæmia cells. (2) This time sequence presents the same features in euploid cells as in aneuploid cells. (3) Incorporation of the DNA precursor is also achieved by the extra-chromosomes. (4) The synthetic phase of the *Y* chromosome in the present case of acute leukæmia differed from that of the small acrocentric chromosomes. (5) The ratio of labelled to non-labelled mitotic figures in the present experiment suggests the possibility that the post-synthetic period is shorter *in vivo* than *in vitro*. (6) The present investigation testifies that a more direct approach to the study of nucleic acid metabolism in leukæmic chromosomes is allowed by the *in vivo* injection of the labelled precursors.

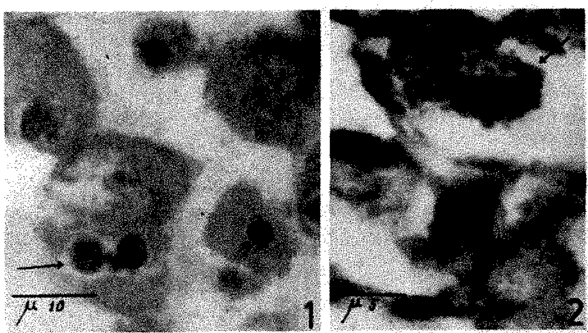
Aggregation of Protein Particles in Tumour Cells

In Walker tumour cells, during experiments carried out with deoxyribonuclease, the formation of particular globules, namely those rising from the aggregation of protein particles (ribosomes), were noted[1]. A similar aggregation occurs[2,3], normally in the oocytes of some animal species (*Patella coerulea, Aplysia depilans, Haliotis lamellosa, Paracentrotus lividus, Sphaerechinus granularis, Arbacia lixula*), which form yolk globules. Observations on the effect of deoxyribonuclease on supravital material confirmed the concept that in the tumour cell there are a large quantity of unorganized ribosomes ('scattered ergastoplasm'), which are not oriented to form identifiable products of synthesis.

Further investigations were undertaken not only on Walker tumour, but also on mammary carcinoma and uterine carcinoma of woman. As formerly pointed out[1], fragments of tumour were placed at room temperature (about 22° C) in an aqueous solution of deoxyribonuclease ('Crystalline' of Light and Co., 10 mg/ml.). Controls were carried out on fragments not submitted to any action, and on fragments kept in distilled water for the same time (minimum, 1 h; maximum, 5 h) at room temperature. The usual fixatives were then used, in particular Bouin's mixture. The results can be summarized as follows:

(1) In Walker tumour cells, rather large globules reduced in number (Fig. 1), and small and very numerous globules appeared in the cytoplasm (Fig. 2); also, in the nuclear area, artificial globules can be seen (Fig. 1).

(2) Artificial globules are also found in the mammary carcinoma (Fig. 4) and in the uterine carcinoma cells (Fig. 3), though in some cases they were rather small.



Figs. 1 and 2. Walker tumour treated with deoxyribonuclease; note in Fig. 1 large globules also in the nuclear area (arrow), and in Fig. 2 the very numerous small globules in the two cells (arrows)

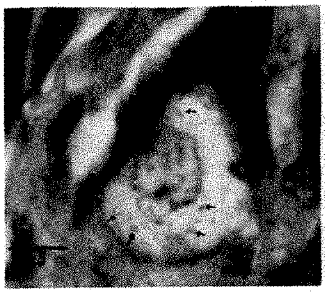


Fig. 3. Uterine carcinoma of a woman treated as in Fig. 1; note small globules (arrows) in the cytoplasm of the cell

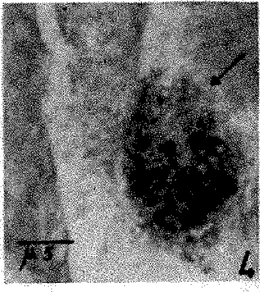

Fig. 4. Mammary carcinoma of a woman treated as in Fig. 1; note the high number of small globules (arrow) in the cell

(3) In the fragments of the three tumours it was observed that the formation of the globules occurs only in the cells of the outer layers of the sections of the preparations treated with enzyme. Very seldom, and especially in some Walker tumour cells of the control preparations kept in distilled water, the presence of globules was noted; this has never been found previously in tumours not submitted to enzyme action before fixation.

(4) In the three tumour cells the globules stain red with hæmatoxylin and eosin and with Mallory's method, yellow with Galgano's (first)[4] method, and blue with Dominici's method. In the same globules, a positive reaction for RNA and for polysaccharides (McManus) has been demonstrated. RNA has been demonstrated with the usual Unna–Pappenheim's method and control with ribonuclease according to Brachet; also with the fluorescence microscope. The observations made with this microscope on sections treated with acridine orange revealed an intense red coloration of the globules; but this colour disappears after the action of ribonuclease. The presence of RNA was established, too, by affinity of the globules for toluidine blue according to Dominici's method; this affinity was suppressed with ribonuclease.

The foregoing observations have confirmed the formation, by artificial means, of protein products, in the form of globules, in the cells of malignant tumours. Subsequent work on several forms of malignant tumours, and also of benign tumours, may render it possible to generalize the process, which could be considered as an artificially induced protein synthesis. In this connexion, it must be ascertained whether the process is to be regarded as a consequence of a change of state of the medium, or rather as a consequence of a modification (also of a chemical nature) of the ribosomes. Experiments must then be carried out in many directions in order to ascertain whether other substances, different from deoxyribonuclease, are capable of provoking an ordered aggregation of such particles.

The question involves, as a side issue, the nature of real alteration of tumour cells, and also the protein synthesis, as apparent from the action of ribonucleoproteins. At present we have no concrete results of the action and the destiny of ribosomes when the incorporation of amino-acids in them is activated by adenosine triphosphate[5,6]. If it were possible to demonstrate that in any event the formation of determined protein substances is realized by aggregation of more or less transformed ribosomes, a new direction would be offered for work on the synthesis of proteins.

GENETICS

Pre-albumin Variations in Primates

THE pre-albumin of the monkey, *Macaca rhesus* (*Macaca mulatta*), has been examined electrophoretically by Blumberg and a possible polymorphism is described. Three types of pre-albumin were evident. In each instance the pre-albumin was presented as a single band.

In an investigation of various primate serum albumins, it was observed on starch-gel electrophoresis, using the lithium–borate discontinuous buffer system of Ashton, that the pre-albumins of higher primates could be distinguished from those of lower primates as shown in Fig. 1. The pre-albumins of man, gorilla, and chimpanzee were each composed of two bands. These three species could not be distinguished by their pre-albumin, as the two bands had a common electrophoretic mobility respectively among the three species. However, in three species of macaques, *irus*, *rhesus*, and *radiata*, pre-albumin variations were evident. *M. irus* and *M. radiata* each presented with a single electrophoretic band which is similar in mobility to the first pre-albumin of the higher primates. *M. rhesus* revealed two pre-albumin bands, neither of which corresponded to either of the two bands of the higher primates. The second band of this monkey may correspond to the single band of monkey type 3 of Blumberg.

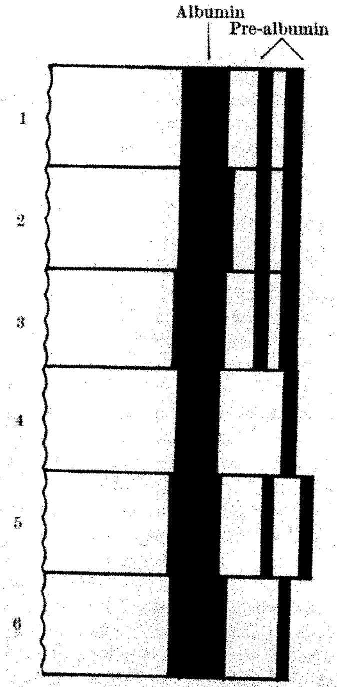

Fig. 1. Diagrammatic representation of the pre-albumins of the following primate serum: (1) human, (2) gorilla, (3) chimpanzee, (4) *Macaca irus*, (5) *Macaca rhesus*, (6) *Macaca radiata*

Thus in the pre-albumin region there appears to be a phylogenetic distinction between higher and lower primates as has been observed in the transferrins. The higher primates, though separated by greater species barriers, appear to have a common pre-albumin pattern, whereas the lower species, all of the same genus, have a polymorphic pre-albumin pattern.

Frequencies of Teratologies among Homozygous Normal Mice compared with those Heterozygous for Anophthalmia

TRYPAN blue has long been known to possess teratogenic properties[1]. Several years ago Barber[2] reported being able to distinguish mouse fœtuses heterozygous for anophthalmia from those which were homozygous normals by the higher incidence among the former of eye defects in response to trypan blue administered to their dams as a teratogenic agent. All cases of defective eye development were unilateral anophthalmia; the expectation, in the absence of the teratogen, was complete bilateral normality. The anophthalmic mutant has been described in detail elsewhere[3,4].

The significance of Barber's findings prompted me to repeat and elaborate on her work. This communication confirms the observation that under appropriate conditions the anophthalmic mutant (*ey*) in a single dose appears to be able to act to bring an animal closer to a threshold for abnormal development than is the case in a homozygous normal individual. That the entire genotype may be involved in the demonstration has been suggested elsewhere[5], and is still being investigated[6]. Another phenomenon described in this communication is the ability of an animal to respond to the treatment with varying degrees of eye reduction on one or both sides; the extreme is complete bilateral anophthalmia. Both eyes are affected, and marked asymmetries in the same individual are not uncommon.

The animals used in this investigation were *ZRDCT-N* and *ZRDCT-An*; the former is normal-eyed, the latter an anophthalmic line. Both were derived by selection from a common stock, differ principally at the *ey* locus, and have been described in detail elsewhere[3]. The *ZRDCT-N* females were mated to their brothers or to *ZRDCT-An* males. Inseminations were detected by the copulation plug method[7]. Counting the day of insemination as day zero, females were injected intraperitoneally with 0·25 c.c. of a 0·3 per cent solution of trypan blue in 0·9 per cent sodium chloride during the seventh, eighth and ninth days *post coitus* (DPC). This was the régime found by Barber[2] to yield the highest frequency of eye defects, a low frequency of skeletal defects and low mortality. Mortality in the present material was very high; skeletal defects did not occur in the series reported here. There is some evidence (unpublished) that the

Table 1. ABNORMALITIES AND MORTALITY AT 18 DAYS *Post-coitus* AMONG TREATED AND UNTREATED LITTERS

In the "Description of abnormalities" column the character to the left of the stroke describes the left eye and the character to the right of the stroke describes the right eye. For an explanation of the symbols see text.

suspension medium of the dye may affect its teratogenic and toxic properties.

Experimentally treated females and untreated controls were killed at 18 DPC. The number of dead and resorbed fœtuses were noted and living fœtuses were examined for eye defects and other gross morphological abnormalities. The results (Table 1) were analysed with respect to the frequency and variety of defects and frequency of fœtal mortality. Although the degree of eye reduction may have been distributed continuously, distinction was made only between unaffected (+ = normal), slight reduction in size (*m* = medium eye), extreme reduction with maintenance of globular shape (*s* = small eye), and complete absence of an eyeball (*an* = anophthalmic). The tests of significance applied to the frequency data were the chi-square test of homogeneity and the Student–Fisher grouped-method *t*-test for the comparison of small samples[8].

Even in this small sample the higher frequency of eye defects occasioned by the teratogen among the group of fœtuses heterozygous for *ey* is highly significant ($t = 3\cdot3$; $df = 49$; $P < 0\cdot001$). This in spite of the slight heterotic vigour suggested by their decreased tendency towards fœtal death ($t = 2\cdot8$, $df = 257$, $P < 0\cdot005$). In most of the *ZRDCT-N* × *ZRDCT-An* matings earlier untreated litters were permitted to go to term as a test of fertility. All of the F_1 generation thus produced were completely normal-eyed. The single anophthalmic fœtus produced in the treated *ZRDCT-N* × *ZRDCT-N* matings was in fact occasioned by the teratogen, since several hundred *ZRDCT-N* progeny produced by routine brother × sister matings were all normal-eyed. Furthermore, in other series of treated *ZRDCT-N* × *ZRDCT-N* matings, additional abnormal young have been obtained both at birth and at 18 DPC.

Whereas the present material appears to allow the detection of *ey* in single dose, this is not the case in all crosses. I have reported[5] differences in response, in comparable crosses involving two sub-lines of the *C57BL* strain of mice. Sub-line 6 responds in much the same way as *ZRDCT-N*, but sub-line 10 does not. In crosses with *C57BL*/10 the effect of *ey* in single dose is masked or overridden by heterotic interaction. It would thus appear that if there were a marked difference in genetic modifiers between the eyeless and normal-eyed strains used in the cross one might not be able to detect the presence of *ey*. That there is a fair degree of variability in the system is also shown by the differences between my own findings and those of Barber. In the present material all degrees of eye reduction were noted. The phenomenon in Barber's material was all or none; either the eye was normal or it was absent.

Although the observations reported here and those of Barber do not constitute rigorous proof, both suggest that *ey* is in fact doing something in single dose, and that under appropriate environmental conditions it is possible to distinguish populations of animals which are heterozygous normal from those which are homozygous normal.

AGRICULTURE

Oversowing Pasture Legumes into the *Hyparrhenia* Grassland of Northern Rhodesia

BECAUSE nitrogen is the key nutrient in plant and animal nutrition in the tropics[1-3], the introduction of effective pasture legumes into the natural grassland is a simple method of raising herbage yield and animal production.

Two promising legumes, *Stylosanthes guayanensis* (*S. gracilis*) ('Stylo') and *Glycine javanica* L., were oversown into undisturbed *Hyparrhenia*-dominant grassland at the Central Research Station, Mazabuka, Northern Rhodesia. The average botanical composition by weight of the veld was: *Hyparrhenia dissoluta* Hubbard 54 per cent; *H. filipendula* Stapf 20 per cent; *Heteropogon contortus* Beauv ex R. and S. 15 per cent; other species 11 per cent. The veld was burnt at the end of the 1961 dry season and the legume seed was oversown in plots after the soil had been scratched with a hand rake to simulate a light cultivation. (Previous work had shown a light cultivation was necessary for the consistently reliable establishment of legumes oversown into the veld.) All plots were given a basal dressing of 200 lb./acre of superphosphate (8·3 per cent phosphorus). At this site, both legumes apparently nodulate effectively without inoculation.

The legume establishment was good. The average density of legumes was approximately 25 plants/sq. ft. on January 28, 1963 (range 14–46 legumes/sq. ft.). The herbage yield of veld alone, veld + 'Stylo' and veld + *Glycine* cut at a hay stage of growth on January 14, 1963, is shown in Table 1. The addition of 'Stylo' doubled the yield of herbage dry matter, increased the yield of crude protein five-fold and increased the calculated yield of digestible crude protein[4] ten-fold, compared with veld alone. The yield increase due to *Glycine* was approximately half that of 'Stylo'.

The usual assumption is that pastures of selected grasses will outyield the native grassland when the

Treatments: No = No fertilizer; *N*1 = 50 lb. N/ac.; *N*2 = 100 lb. N/ac.; *N*3 = 200 lb. N/ac. (nitrogen as urea).

nutrition and management are improved. But when *Hyparrhenia* veld at Mazabuka was directly compared at four levels of nutrition with Giant Rhodes grass (*Chloris gayana* Kunth), a standard pasture species, the yield of veld was greater than the Rhodes grass (Table 2). Thus there is no evidence as yet for the need to plough up and resow vigorous *Hyparrhenia* grassland, especially if pasture legumes can be fairly easily introduced into the veld.

Because cattle nutrition in this territory is generally limited by their protein intake[5], the ten-fold increase in digestible crude protein that resulted from sowing 'Stylo' into the veld should allow a large potential increase in animal production.

VIROLOGY

Use of Synergy in the Identification of Strains of Citrus Yellow Vein Virus

IN 1957 a virus-induced vein yellowing disease was found in four Eustis limequat (*Citrus aurantifolia* (Christm.) Swing. × *Fortunella japonica* (Thunb.) Swing.) trees in California[1]. Although the virus has been shown experimentally to have a wide host range within the citrus family, it has not been found to occur naturally in other limequat trees or any other citrus plants. Cross-protection examination revealed that although the yellow vein virus will interact in various ways with certain of the other citrus viruses, it is not related to them[2,3]. This communication presents evidence of the existence of strains of the yellow vein virus based on cross-protection tests and studies of the synergistic interaction between yellow vein and vein enation viruses.

Symptoms in plants singly infected with yellow vein virus are usually very mild and restricted mostly to yellowing of veins of an occasional leaf followed by recovery or lack of symptoms in subsequent growth. Grafts from recovered plants frequently fail to transmit yellow vein virus. When the symptomless plants are inoculated with the unrelated virus of vein enation, severe yellow vein symptoms reappear and severe dwarfing results. Because of the unusual and erratic behaviour of yellow vein virus when it occurs alone, making the identification of strains based on symptom expression and cross-protection reactions unreliable, the differentiation of strains of yellow vein virus was made by combining it with the vein enation virus and examining the variation in synergistic response.

The same grafting techniques described in another paper[4] were used in these investigations. Two of the four virus-infected Eustis limequat trees, designated Tulare and Coachella, were used as virus donors. The remaining two yellow-vein-virus-infected limequat trees were found to be unsuitable as donors because they also carried other citrus viruses. Vein enation virus came from a citrus plant that had been infected experimentally by *Myzus persicae* (Sulz.). Virus-free Mexican lime, *C. aurantifolia* (Christm.) Swing., and rough lemon, *C. jambhiri* Lushington, were used as indicator plants.

Virus-infected Mexican lime and rough lemon plants exhibit two distinct types of vein yellowing, depending on the source of the yellow vein virus interacting with the vein enation virus (Fig. 1). One (Tulare + vein enation) consists of severe yellowing of the veins of every leaf of the plant and severe dwarfing. In some cases plants infected with this virus combination are killed. The other (Coachella + vein enation) shows milder vein yellowing, with fewer leaves affected, and less dwarfing. These symptoms, referred to in this communication as 'mild' and 'severe', remain constant and unaltered. Transfers of buds from the mild and severe types to healthy indicator plants, in every case, produced the mild and severe symptoms. In no instance did the mild strain (Coachella) induce severe (Tulare) symptoms or vice versa.

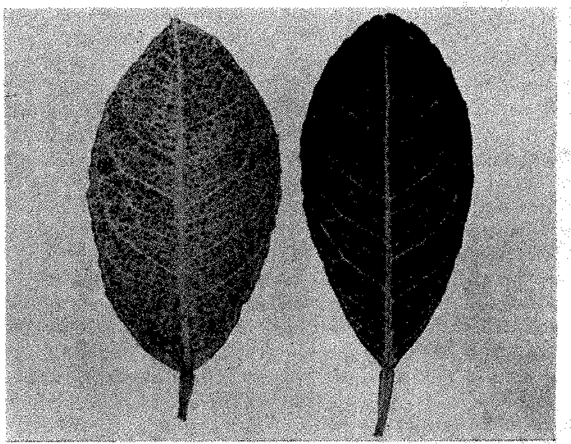

Fig. 1. Leaves of rough lemon infected with yellow vein and vein enation viruses. Left, severe yellow vein + vein enation viruses; right, mild yellow vein + vein enation viruses

In a series of cross-protection experiments, tissue from plants with the severe symptoms was grafted into plants with the mild type of symptoms to determine if the mild type would prevent or interfere with infection by the severe type. Protection was evident in all cases. The challenged plants with the mild symptoms remained unchanged. Transfers of tissue from the challenged plants to healthy indicator plants failed to induce the severe yellow vein symptoms or any evidence of a blend of the two types. These results indicate that cross-protection is effective and that the mild and severe symptoms are caused by strains of the same virus when each reacts synergistically with vein enation virus, rather than by different viruses.

From the results presented here it is concluded that the virus inducing yellow vein in citrus exists as strains. Two distinct strains are recognized. Strain Tulare is considered the severe strain which, in combination with vein enation virus, causes severe synergistic reactions in plants used in these tests. Strain Coachella causes milder synergistic responses in the indicator plants when combined with vein enation virus and is identified as the mild strain.

The discovery of strains in the yellow vein virus is interesting because of employment of the interactions between unrelated viruses to differentiate related strains of a virus. In this situation synergy appears to magnify the differences between related strains, making them more easily distinguishable. Attempts to separate strains of vein enation virus based on this synergistic reaction between it and yellow vein virus are now being made.

I thank Mr. M. K. Harjung for valuable assistance.

STATISTICS

Analysis of Spray-drop Data

THE spray-drop method of Williams and Backus[1,2] is a valuable technique in electron microscopy for the estimation of virus concentrations. A statistical analysis was described in the original papers[3]. In 1958 we showed[4] that this analysis was valid and gave a test to check that in any estimation the pairs of numbers used were unlikely to contain variations due to causes other than purely random ones. We pointed out that the ratio between the number of virus (V_i) and the number of latex (L_i) in the ith drop can be expected to vary between one drop and the next for two reasons. There is the variation due to random movements of the particles, both virus and latex, in suspensions at ordinary temperatures which introduces an uncertainty into whether a particle is in or not in a drop at the instant of formation. This introduces a variation in the numbers of particles expected in drops of the same size from a uniformly mixed suspension. It will have a Poisson distribution and has been termed by us inherent variation. The second reason is due to experimental factors—inadequate mixing, contamination during spraying, aggregation of particles, etc., and these have been termed induced variations. Our test shows whether the pairs of numbers obtained from a series of drops contain variations in excess of that which would be expected from the inherent variation alone. This test does not make any assumption about drop size and may be applied to a collection of droplets of any size distribution.

Opfell[5] has described a non-parametric test to discover any defects in the experimental technique. Such non-parametric tests (though usually less precise than parametric ones) are useful, but Opfell appears to have misunderstood the principles of our test when he justifies the need for his non-parametric one by implying that our test is insufficient by itself. Thus he says, "If the raw data satisfy the Williamson and Taylor tests and are free from induced variation arising from large variation in droplet size . . .", but he does not explain what induced variation he expects to get arising from "large variation in droplet size". Variation in droplet size does not itself add further induced variation, and our test checks for induced variation from all causes. Thus, if our test is satisfied, then it is reasonable to infer that the experimental data are satisfactory.

Watson[6] has published a statistical analysis based on correlation coefficients and regression lines. We have already pointed out[4] that correlation coefficients by themselves are misleading, and regression line analysis as presented by Watson is therefore unsatisfactory. He finds the regression line for V on L and compares the standard error of the estimate of V with the intercept of the line on the V axis. If the error is the greater, Watson considers that the regression is a straight line not significantly different from a line through the origin. If the standard error is less than half the intercept, then he considers the straight line is significantly different and the correlation (no matter how good) does not indicate consistency of the virus/latex ratio. In fitting the regression line as V on L, Watson tacitly assumes that the values of L are exact compared with V for each drop. This is not valid, as pointed out here, because inherent variations are present in both V and L. A regression line fitted so that it passed through the origin and the sum of the squares of the perpendiculars from each point to the line is a minimum would give the correct best estimate of the ratio from the slope of the line, but no estimate of the presence of induced variation would be possible since correlation coefficients as a test for consistency are of no value in this case.

Other authors[7,8] have used the χ^2 test. The values of χ^2 are very close to the values of $2F$ obtained from our test and which is itself distributed as χ^2. It is important to bear in mind the criteria which the tests are checking. Our likelihood test is an approximate test for the following two criteria. (*a*) If we could obtain many drops of exactly the same size the number of particles in them would form Poisson distributions about means ν_i and μ_i for the virus and latex respectively, (*b*) the ratio $\varkappa_i = \nu_i/\mu_i$ is constant for all i, that is, all drops.

The simple χ^2 test is an approximate test for the one criterion as expressed in (*b*). This test makes no recognition of any distribution such as (*a*).

It is also important to consider the approximations involved. The maximum likelihood test is approximately true for a large number of drops regardless of the counts within the drops. The ordinary χ^2 test is approximately true only when both the number of drops is large and the numbers within each drop are large (or made large by compounding drops). However, in most experiments the numbers involved are sufficiently large.

The values of χ^2 from the two tests usually differ. It can be shown that for a large number of drops

$$\chi^2_L = \chi^2_K\left(2 - \frac{R + 1/R}{r_i + 1}\right)$$

where χ^2_L is the component of χ^2 due to V_i and L_i counts in the ith drop in the likelihood test, χ^2_K is the component of χ^2 for the ith drop in the ordinary test,

$$r_i = V_i/L_i,\ R = \Sigma V_i/\Sigma L_i$$

Thus the contribution of the ith drop to the χ^2 of the likelihood test can be greater or less than the χ^2 of the ordinary test.

It appears that all authors determine the ratio of virus to latex in the valid way that is ($R = \Sigma V_i/\Sigma L_i$). We conclude, however, that not all authors use a valid test to check their data before computing this ratio. Any test based on correlation coefficients (and therefore including regression analysis) is in our opinion unreliable. The ordinary χ^2 test may be used, but being a general test for the equality of proportions may lead to the acceptance of data which on a more stringent test would be rejected. The method we have proposed represents the classical statistical approach applied to this problem and provides a solution in an easily workable form. The criteria tested are more stringent than the ordinary χ^2 test since a further requirement is added that the numbers of particles in drops of identical size would be Poisson distributed

A Method of Calculating Net Assimilation Rate

A USEFUL measure of the photosynthetic efficiency of plants is 'net assimilation rate' (E) defined by Gregory[1] as the rate of increase of dry weight (W) per unit of leaf area (L), that is

$$E = \frac{1}{L}\,\frac{\mathrm{d}W}{\mathrm{d}t} \qquad (1)$$

In measuring W the plant is destroyed, so changes in W can be determined only by successive sampling from a population of plants, involving sampling errors In practice samples are commonly taken at intervals of 1–4 weeks for measuring both W and L The paired W and L sample means may then be used to calculate E_M, an estimate of the mean E for each time-interval $(t_2 - t_1)$, usually as proposed by Gregory[2]

$$E_M = \frac{(\bar{W}_2 - \bar{W}_1)(\log_e \bar{L}_2 - \log_e \bar{L}_1)}{(t_2 - t_1)(\bar{L}_2 - \bar{L}_1)} \qquad (2)$$

Application of this formula to data recorded by one of us (J.C S A) in an experiment on partial defoliation of maize gave the results shown in Table 1

Table 1 MEAN VALUES OF E_M (G/M²/WEEK)

	Period in weeks after flowering			
	0–2	2–4	4–6	6–8
Control	42 0	23 5	33 1	27 8
Defoliated	43 2	25 9	25 3	36 1
S E	±3 8	±4 2	±6 1	±9 3

There were 6 plots of partially defoliated plants and 6 of controls Samples of 9 plants were taken from each plot at fortnightly intervals 0–10 weeks from flowering The L values at week 10 and hence the E_M values for weeks 8–10 were unreliable because of the large number of senescent leaves, and have been omitted from Table 1 The standard errors are calculated from the variation between replicates

The errors of Table 1 are large and the values fluctuate erratically, particularly in the later periods This is because differences in W, which are subject to large errors, have to be taken and the errors of successive differences are negatively correlated

It occurred to us that these errors might be greatly reduced by fitting smooth curves to W and L, an approach which appears to have been overlooked by previous writers on this subject (see Watson[3] for a review and bibliography)

In this experiment quadratic curves gave a satisfactory fit, as is shown by Fig 1 The *S E* s of W were calculated from the variation between replicates; this tended to increase with time but was reasonably homogeneous over all dates after a log transformation The *S E* s shown in Fig 1 are the de-transformed values derived from the single pooled *S E* of log W In order to provide estimates of E and their errors quadratic curves $W = a + bt + ct^2$ and $L = a' + b't + c't^2$ were fitted to the W values (including week 10) and the L values (up to week 8) for each plot separately From (1) it follows that

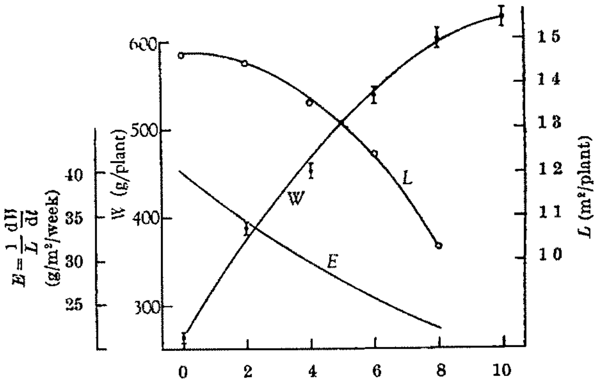

Fig 1 Changes in dry weight (W), leaf area (L) and net assimilation rate (E), of maize plants during 10 weeks following flowering

$$E = \frac{b + 2ct}{a' + b't + c't^2}$$

This was evaluated for each plot for $t = 0, 1, 2$ 8 weeks The treatment means of the values for $t = 1, 3, 5, 7$ (the mid-points of the intervals used in Table 1) are shown in Table 2, and a graph of the mean E of the control plots is included in Fig 1

Table 2 MEAN VALUES OF E (G/M²/WEEK)

	Period in weeks from flowering			
	1	3	5	7
Control	37 0	32 0	27 7	23 8
Defoliated	39 0	32 1	26 0	22 2
S E	±2 2	±1 6	±1 6	±2 2

The results of Table 2 are much more regular than those of Table 1, and the errors are much smaller. The values for the different times are not, of course, independent, but differences between treatments (for example, for average effect and rate of change) can be tested, in cases of doubt, by calculating the mean (m) and regression coefficient (b) of a suitable selection of calculated E values for each plot and comparing the treatment mean m and b values Thus we have

	$\bar{m}$		$\bar{b}$	
Control	30 1	(±1 5)	−2 2	(±0·5)
Defoliated	29 8	(±1 5)	−2 8	(±0 5)

The general falling trend of E with time is well established, and the absence of treatment effect is shown by the non-significance of m and b differences

Inherent in the curve-fitting method is a smoothing out of any deviations from the general trend of E with time. This loss is of no consequence here as the apparent deviations seen in the E_M figures are of little statistical significance and, even if to some extent genuine, are irrelevant to the main purpose of the investigation

The method is essentially empirical, and there is no necessity for the parameters of the curves to have biological significance, provided that the curves adequately describe the time changes of W and L

Monday, November 25

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W C 2), at 2 30 p m and 5 30 p m —Colloquium on "Recent Advances in D C Amplifiers".

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W 12), at 4 p m —Prof A W Woodruff "Recent Advances in Tropical Medicine" *

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Lecture Theatre of the Science Museum, Exhibition Road, London, S W 7), at 5 30 p m —Mr S C Goddard "Louis Ducos du Hauron and the Early History of Colour Photography"

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Is Load Shedding Necessary and How Can Its Effects be Minimized?" opened by Mr A E Hawkins

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 5 30 p m —Dr E Schatzman (Paris) "Nuclear Reactions at the Surface of Stars and Stellar Evolution" *

BRITISH MEDICAL ASSOCIATION (at the National Hospital for Nervous Diseases, Queen Square, London, W C 1), at 6 p m —Dr Macdonald Critchley, F R C P "The Problem of Visual Agnosia" (Twelfth Victor Horsley Memorial Lecture)

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 6 p m —Dr T Vickerstaff "Scientific Aspects" (Second of three Cantor Lectures on "Colour in Modern Life")

Tuesday, November 26

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr W A Smeaton "Early Balloon Ascents, 1783–1795".*

UNIVERSITY OF LONDON (at Imperial College, London, S W 7), at 1 30 p m —Mr D E Broadbent "Adjusting to the Environment Learning". (Fourth of five lectures on "The Basis of Experimental Psychology")*

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S W 1), at 5 30 p m —Mr R A Stephenson and Mr O T Barfod "Tanker Accommodation in the Mersey at Tranmere"

RESEARCH DEFENCE SOCIETY (in the Physiology Lecture Theatre, University College, Gower Street, London, W C 1), at 5 30 p m —Sir John Ritchie, C B "The Eradication of Bovine Tuberculosis and its Importance to Man and Beast" (Thirty-second Stephen Paget Memorial Lecture), followed by the Annual General Meeting

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5 30 p m —Prof R L F Boyd "Exploration of the Upper Atmosphere by Space Vehicles" (Afternoon Lecture for Sixth Form Boys and Girls from Schools in London and the Home Counties Further Lectures on November 27 and December 3 and 4)

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr W E van Heyningen "The Bacterial Neurotoxins" (Twelfth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

INSTITUTION OF ELECTRICAL ENGINEERS, and the ROYAL AERONAUTICAL SOCIETY (at the Institution of Electrical Engineers, Savoy Place, London, W C 2), at 6 p m —Discussion on "Installation Aspects with Particular Reference to the Cooling of Electrical Equipment in Aircraft" opened by Mr P A Amer

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Symposium on "The Design of Small Mass-Produced Motor Car Engines"

UNIVERSITY OF LONDON, and the INSTITUTE OF BANKERS (in the Library of the Institute of Bankers, 10 Lombard Street, London, E C 3), at 6 p m —Dr T A Margerison "Britain To-morrow—a Consideration of How Best to Mobilise Her V Scientifically".

SOCIETY FOR ANALYTICAL CHEMISTRY, PHYSICAL METHODS GROUP (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 6 30 p m —Nineteenth Annual General Meeting, followed by Dr. W Cule Davies "Selection of a Physical Method"

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS AND POLYMER GROUP (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Dr J Idris Jones "Organo Aluminium Polymers"

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the SOUTH-EAST ESSEX TECHNICAL COLLEGE CHEMICAL SOCIETY, at the South-East Essex Technical College, Longbridge Road, Dagenham), at 7 p m —Mr. W G Busbridge "Isotopes in Industry"

SOCIETY OF INSTRUMENT TECHNOLOGY, SYSTEMS ENGINEERING SECTION (at Manson House, 26 Portland Place, London, W 1), at 7 p m.—Mr V A Gault "Lift Control Using Static Switches"

Tuesday, November 26—Wednesday, November 27

ASSOCIATION FOR THE STUDY OF ANIMAL BEHAVIOUR, and the ZOOLOGICAL SOCIETY OF LONDON (in the Meeting Room of the Zoological Society of London, Regent's Park, London, N W 1), at 10 30 a m daily—Symposium on "Social Organisation of Animal Communities"

IRON AND STEEL INSTITUTE (at Church House, Great Smith Street, London, S W 1), at 9 45 a m on Tuesday, and 10 a m on Wednesday—Autumn General Meeting Conference on "Fume Arrestment in Steelmaking Processes"

Wednesday, November 27

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 2 p m —Dr H Lehmann "Genes and Molecules".*

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (at 14 Belgrave Square, London, S W 1), at 3 p m —Meeting on "The 1963 Food Group Summer Conference and Tour in the Netherlands".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "The Application of Electronic Building Bricks" opened by Mr. I V Idelson and Prof. J E B. Gray

INSTITUTION OF ELECTRICAL ENGINEERS, POWER DIVISION (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "High Voltage Generation and Distribution of A C in Ships" opened by Mr D Gray

BRITISH INSTITUTION OF RADIO ENGINEERS (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 p m —Annual General Meeting, followed by the Presidential Address of Mr J L Thompson

SOCIETY FOR VISITING SCIENTISTS (at the English-Speaking Union, Dartmouth House, 37 Charles Street, London, W 1), at 7 30 p m —Discussion Meeting on "Science Centres". Chairman Prof A Haddow, F R S Speakers Mr J E Cummins and Sir Robert Robinson, O M , F R S

Thursday, November 28

PLASTICS INSTITUTE, REINFORCED PLASTICS GROUP (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 10 a m —Conference on "Sandwich Construction".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr J L Watling "Can There be Two Things Exactly Alike?"*

ROYAL SOCIETY OF ARTS, COMMONWEALTH SECTION (at John Adam Street, Adelphi, London, W C 2), at 5 15 p m —Mr Tom Harrisson "100,000 Years of Stone Age Culture in Borneo".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W C 2), at 5 30 p m —Mr F J D Taylor, O B E , Mr W J Bray and Mr R W White "The Results of Tests at Goonhilly with the Experimental Earth Satellites Telstar and Relay"

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Consideration of the Practical Applications of Lasers" opened by Dr Denis Taylor and Dr R P Howson

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr A P Waterson "The Structure of Viruses" (Thirteenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the BATTERSEA COLLEGE OF TECHNOLOGY CHEMICAL SOCIETY, at the Battersea College of Technology, Battersea Bridge Road, London, S W 11), at 6 30 p m —Prof J Lewis "Magnetic Criteria for Stereo-Chemistry of some Cobalt II Complexes"

Friday, November 29

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Du Cane Road, London, W 12), at 10 a m —Dr Audrey Smith "Survival of Frozen Cells, Tissues, Organs and Animals" *

INSTITUTE OF INFORMATION SCIENTISTS (at the Swedenborg Society Hall, 20 Bloomsbury Way, London, W C 1), at 6 15 p m —Mr Robert Maxwell "The Economics of Publishing Scientific Material"

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 9 p m —Sir Charles Percy Snow, C B E "The Two Cultures and the Sorcerer's Apprentice"

Saturday, November 30

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W 1), at 2 30 p m —Anniversary Meeting

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Mr Raymond Clausen "Some Aspects of Music and Life To-day in Malekula, New Hebrides" *

BOTANICAL SOCIETY OF THE BRITISH ISLES (in the Botany Department, British Museum (Natural History), Cromwell Road, London, S W 7), from 2 p m to 5 30 p m —Annual Exhibition Meeting

Monday, December 2

UNIVERSITY OF LONDON (at the Royal Veterinary College, Royal College Street, London, N W 1), at 4 p m —Prof John Francis (University of Queensland) "Veterinary Research and Education in Australia" *

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W C 2), at 5 30 p m —Mr F Horner "Atmospheric Radio Noise as a Problem in Radio Communications"

BRITISH INSTITUTION OF RADIO ENGINEERS, COMPUTER GROUP (joint meeting with the COMPUTER GROUP of the INSTITUTION OF ELECTRICAL ENGINEERS, at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 p m —Symposium on "Analogue Circuit Techniques using Transistors".

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "Some Experience on Projects in Courses for Diplomas in Technology"

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W C 2), at 6 p m —Mr Hulme Chadwick "Colour and Community". (Last of three Cantor Lectures on "Colour in Modern Life")

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Mr H R Hearn "Technical Developments in the Aerosol Field"

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8 15 p m —Mr Norman G Dyhrenfurth "America on Everest".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Physicist (Basic grade), initially for training and routine work on the physical aspects of radiotherapy (including high energy X- and Gamma-radiations)—The Secretary, Mount Vernon Hospital, Northwood, Middlesex (November 29)

Experimental Officer or Senior Experimental Officer in the Department of the Mechanics of Fluids, for duties which will include the design and construction of electronic apparatus for use in fluid mechanics research—The Registrar, The University, Manchester 13 (November 30)

Lecturer/Assistant Lecturer (with a good honours degree and research experience) in Botany—The Staff Officer, College of Advanced Technology, Gosta Green, Birmingham 4, quoting Ref 11/63/6 (November 30)

Research Assistant (with a good honours degree in physics, chemistry or metallurgy) in Applied Science, to work with Dr W G Townsend in the Electrical Engineering Laboratories on problems associated with the surface chemistry of semiconductor materials and other related effects—Dr W G Townsend, Engineering Department, University College of Swansea, South Wales (November 30)

Senior Lecturer in Mathematics—The Secretary, Royal College of Science and Technology, George Street, Glasgow, C 1 (November 30)

Sub-librarian (with a good honours degree and preferably professional qualifications and appropriate experience) in the Faculties of Medicine and Veterinary Science—The Registrar, The University, Liverpool, quoting Ref. No CV/440/N (November 30).

Lecturer (with research interests in the field of organic molecular physics) in Physics—The Registrar, The University, Manchester 13 (December 1)

Lecturer (with a good honours degree and professional or research experience in civil or mechanical engineering) in the Department of Engineering—The Secretary, The University, Aberdeen (December 4)

Lecturer (with an honours degree in mathematics) in Mathematics in the Department of External Studies, University of Queensland, Brisbane, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W 1 (London and Brisbane, December 6)

Assistant Librarian (honours graduate with library qualifications)—The Secretary, The Queen's University, Belfast, Northern Ireland (December 10)

Lecturer/Senior Lecturer in Physical Chemistry at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (South Africa and London, December 10)

Senior Teaching Fellows and Teaching Fellows in the Department of Mathematics, Monash University, to assist in the teaching of one or more of the following subjects applied mathematics, pure mathematics and mathematical statistics—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1, or The Registrar, Monash University, P O Box 92, Clayton, Victoria, Australia (Australia and London, December 13)

Senior Teaching Fellows and Teaching Fellows in the Department of Physics, Monash University—The Secretary Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1, or The Registrar, Monash University, P O Box 92, Clayton, Victoria, Australia (Australia and London, December 13).

Senior Teaching Fellows and Teaching Fellows in the Department of Zoology and Comparative Physiology at Monash University—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London S W 1, or The Registrar, Monash University, P O Box 92, Clayton, Victoria, Australia (Australia and London, December 13).

Lecturer, and an Assistant, in Mathematics—The Secretary of University Court, The University, Glasgow (December 31)

Chair of Applied Mechanics within the Department of Mechanical Engineering—The Registrar, The University, Liverpool, quoting Ref CV/453/N (January 11)

University Lecturer in Physiology (some preference may be given to a candidate with interests in the general field of body fluids and electrolytes)—The Administrator, Department of Physiology, The University, South Parks Road, Oxford (January 31)

Assistant Experimental Officer (with a pass degree or H N C or, if under 22, G.C E "A" level (preferably in chemistry and zoology), O N C, or equivalent), for a programme of research on the biochemistry of lipids and their possible significance in cardiovascular degeneration in experimental animals—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, near Reading, quoting Ref 63/N/13

Associate Professor in Pharmacology—Prof M F Murnaghan, Faculty of Medicine, University of Ottawa, Ottawa, Canada

Head (with a higher degree, an established field of research in electrical engineering, and a number of years of university teaching experience) of the Department of Electrical Engineering, Nova Scotia Technical College—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall London, S W 1, and President G W Holbrook, Nova Scotia Technical College, Halifax, Nova Scotia, Canada

Lecturer or Senior Lecturer (man or woman, preferably with teaching experience and a knowledge of modern methods) in Mathematics in the Training Department, to share in courses for the B A and B Sc (General) degrees and the three-year Teachers' Certificate—The Registrar, Goldsmith's College (University of London), New Cross, London, S E 14

Official Tutorial Fellowship in Physiology—The Master, St Catherine's College, Oxford

Post-doctoral Research Fellow, for work on a mass spectrometric study of gas reactions in shock waves—Prof J E Dove, Department of Chemistry, University of Toronto, Toronto 5, Ontario, Canada

Research Assistant (with an honours degree and research experience in the field of mechanical properties of materials), to take day-to-day charge of a research project on the fracture of metals and non-metals—Dr R D Hoyle, Mechanical Engineering Department, Imperial College of Science and Technology, London, S W 7

Research Associate (with a Ph D or honours B Sc in physiology or pharmacology), to investigate mechanism of action of sympathomimetic amines on the tissues of the eye, with special reference to their action on intraocular dynamics—Dr M E Langham, Department of Ophthalmological Research, Wilmer Institute, Johns Hopkins Hospital, Baltimore 5, Maryland, U S A.

SCIENTIFIC FELLOWSHIPS IN EUROPE

The CIBA Fellowship Trust (which was founded by the CIBA Companies of Great Britain for the purpose of improving and increasing the interchange of ideas between scientists in the United Kingdom and on the Continent) will award a number of CIBA Fellowships to enable graduates of Universities of the U K , Northern Ireland and Eire (who may be at present either at a University or in industry) to carry out research at Continental Universities in chemistry, physics or some other allied scientific subject. These Fellowships (of a basic value of £600 for pre-doctoral and £900 for post-doctoral Fellows, plus appropriate additional allowances depending on place of study, etc) will be tenable for at least one year, with the possibility of renewal for a further one or two years, and will be awarded in April, 1964

Those interested should write to the Secretary of the CIBA Fellowship Trust, CIBA United Kingdom Limited, 96 Piccadilly, London, W 1, who will provide full details and application forms The closing date for applications is January 15, 1964

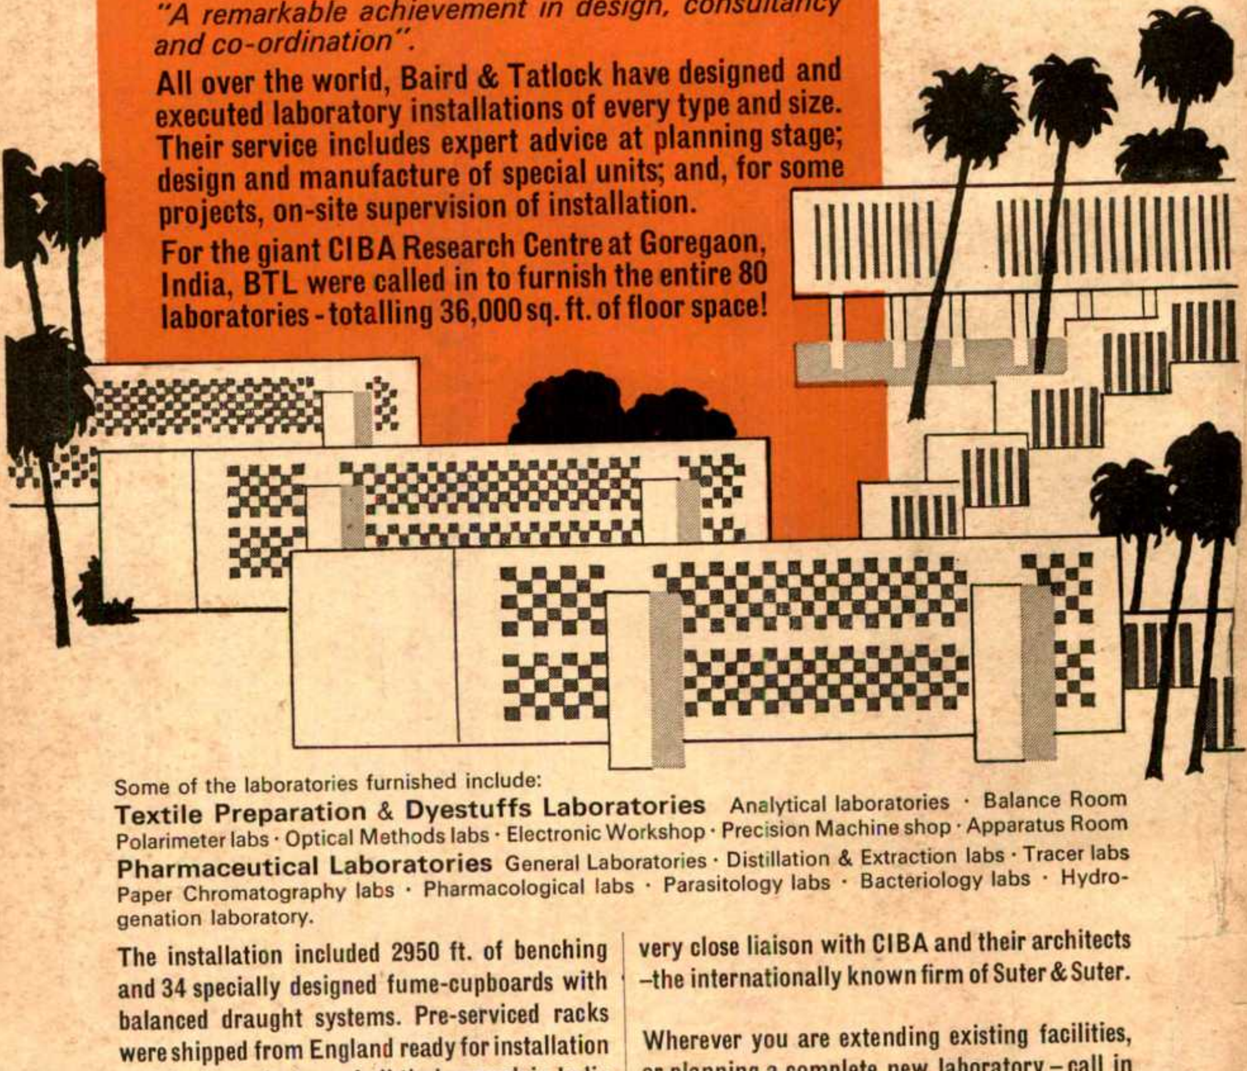
COMPLETELY FURNISH THE LABORATORIES OF SOUTH ASIA'S LARGEST RESEARCH CENTRE!

"A remarkable achievement in design, consultancy and co-ordination".

All over the world, Baird & Tatlock have designed and executed laboratory installations of every type and size. Their service includes expert advice at planning stage; design and manufacture of special units; and, for some projects, on-site supervision of installation.

For the giant CIBA Research Centre at Goregaon, India, BTL were called in to furnish the entire 80 laboratories - totalling 36,000 sq. ft. of floor space!



Some of the laboratories furnished include:

Textile Preparation & Dyestuffs Laboratories Analytical laboratories · Balance Room Polarimeter labs · Optical Methods labs · Electronic Workshop · Precision Machine shop · Apparatus Room

Pharmaceutical Laboratories General Laboratories · Distillation & Extraction labs · Tracer labs Paper Chromatography labs · Pharmacological labs · Parasitology labs · Bacteriology labs · Hydrogenation laboratory.

The installation included 2950 ft. of benching and 34 specially designed fume-cupboards with balanced draught systems. Pre-serviced racks were shipped from England ready for installation and the manufacture of all timber work in India was closely supervised by BTL's design consultants, who, at all stages of the project worked in very close liaison with CIBA and their architects –the internationally known firm of Suter & Suter.

Wherever you are extending existing facilities, or planning a complete new laboratory – call in the BTL Furnishings Division! This is the first step towards the speedy and successful completion of your laboratory project.

PRESIDENT JOHN KENNEDY

News of the assassination, on November 22, 1963, of President Kennedy of the United States of America must by now have reached every part of the world.

Many columns of print, and numerous comments by radio and television, have already revealed the disgust and anguish at this senseless, indeed monstrous, act; moreover, from every country have gone messages of sincere sympathy with Mrs. Kennedy and all other members of the late President's family.

Nevertheless "Nature" feels that a special note of sympathy should be expressed, not only to the late President's family, but also to every American scientist from all other scientists throughout the world. Apart from the personal tragedy, we as scientists recognize that in more than one capacity the late President exerted a profound influence on scientific research and development, and its impact on world affairs—an influence which spread far beyond the frontiers of the U.S.A.

In our special field of human endeavour, therefore, we must remember this, and so deplore its loss.

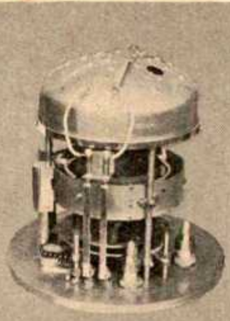
PHYSICS DEPARTMENTAL LIBRARY

Vacuum Coating Units Series 12E

The 12E Series is readily available with a comprehensive array of chamber accessories and different pumping systems specially developed for research applications, pre-production investigations and small-scale production.

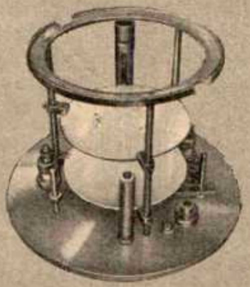
Applications include: all evaporation and sputtering duties, anti-reflection coatings, shadow-casting, multi-layer coatings, lens blooming, front-surface mirrors, surface replication, cathodic etching and all general requirements of electron microscope work.

EARLY DELIVERY



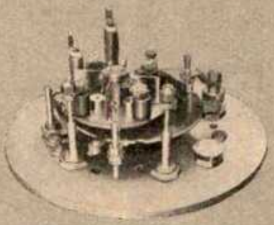
LENS BLOOMING ASSEMBLY

Showing radiant heater covering undrilled spherical workholder, h.t. discharge cleaning electrodes and 4-position source turret.



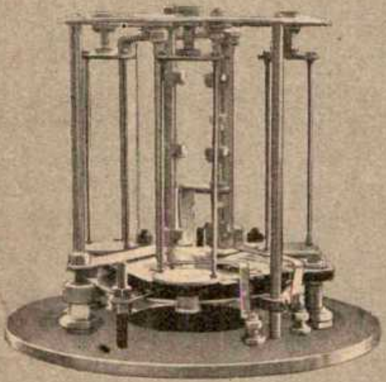
CATHODE-ANODE ASSEMBLY

To enable the units to be used for sputtering duties the 4¾ in. (121 mm.) diameter cathode is mounted beneath the top support plate on stand-off insulators.



4-POSITION EVAPORATION SOURCE

Shows filaments in position to enable four materials to be evaporated in any order from the same centre point. Sequential evaporation can also be carried out.



TRIPLE-SPOOL WORKHOLDER

For accurately metallising small intricate objects. The spools rotate for all-round uniform coating.

YEARS AHEAD WITH

Pye precision

The remarkable performance of the Pye Type 6001 Precision Instrument Switch has made possible what can best be described as a 'breakthrough' in the design of Precision Potentiometers. This is evidenced by the exceptional accuracy and ease of operation and read-out so fully realised in the Pye Decade Potentiometer.
The Type 6001 Switch has also been incorporated in a new range of Pye Wheatstone Bridges and Resistance Boxes thus ensuring that faultless performance will be maintained over many years of continuous use.
In support of these fine measuring instruments is a wide selection of null point indicators and other accessories. Most significant are the Scalamp Galvanometers, known and used in every part of the world, and a new range of Freely Suspended Reflecting Galvanometers. The catalogue which describes all of these instruments can be sent to you today.

Branches in London, Manchester and Glasgow

TAS/DO.13

BCM 200 REFRACTORY CUTTING MACHINE

HIGH SPEED PRECISION CUTTING OF REFRACTORIES, SEMICONDUCTORS AND CERAMICS

- Cutting Disc Diamond Impregnated 12″ dia. Max. depth of cut 3¾″.
- Table mounted on vee guide rollers fitted with needle roller journal and thrust bearings.
- Area 11″ × 17″, with tee slots for clamping.
- Mitre rest and work clamp fitted to table.
- Spindle fitted with taper roller bearings.
- Fully protected from abrasive sludge.
- Vibration free drive powered by 1½ horse power motor. All electrics totally enclosed in pedestal.
- Coolant mainwater or soluble oil.
- Finish Grey Stove Enamel.

TRADE UNIONS: THE CALL TO REFORM

THE Broadsheet by B Donoghue, assisted by A. Oakley and Janet Alker, *Trade Unions in a Changing Society**, is part of a three-year study of the subject which is being carried out by Political and Economic Planning It was issued two months before the report on economic development and planning, which urged the Trade Unions to undertake the institutional changes required to enable them to function effectively in a world which increasingly requires economic planning, but although the report was adopted by the Trades Union Congress at Brighton in September, no positive proposals were advanced A further report on the British Trade Union structure was promised for next year, and, in the meantime, the Broadsheet should encourage the constructive thinking within the Unions that is essential as a first step to reforms that must come from the General Council if not from the Unions themselves

The Broadsheet follows an earlier study, issued in July 1962, of Trade Union membership, and shows even more clearly than the first Broadsheet the new functions which the Trade Unions must exercise in a changing society and the urgent need for an improvement in the organization and structure of the Unions, indeed, of the whole Trade Union situation in Britain It is obvious from the Broadsheet and from the debates at Brighton that some improvement in management would ameliorate the situation, if only by removing some of the excuses advanced by the Unions for not undertaking reforms, and this may well be the only material contribution that can come from outside Nevertheless, the Broadsheet displays dispassionately the realities of the situation and the danger to society as a whole if the Trade Unions continue to ignore these realities and fail to discover for themselves a new and relevant sense of purpose and fail to adjust their functions and organization accordingly

Some trade unionists may disagree with particular interpretations made in the Broadsheet, and there may well be a disposition to ignore some of the changes in our whole social and economic life and outlook, or at least to imagine that the responsibility for change and adaptation in institutions or relationships is solely a Government responsibility The changes, however, are too deep and fast for this to be a party political matter, and the Broadsheet is careful to avoid making them a party issue It points out, nevertheless, that the troubles which afflict industry and especially the Unions ultimately injure all members of the community and that there is a common advantage to be gained from ending them and a common responsibility to work towards ending them If, in fact, the Trade Union movement fails to ask itself honestly the basic questions about its position in the changed and still changing Britain, to answer them honestly and take the necessary action, in spite of difficult and even painful adjustments, the Unions must become increasingly anachronistic and will be unable to make positive contributions to the new society which is emerging in Britain

The Broadsheet begins by quoting from a speech by Mr George Woodcock to the Trades Union Congress in September 1962, in which he urged the Unions to do just this to enquire into Trade Union purpose, to ask themselves what they were here for and then to discuss the kind of structure which would enable them to serve that purpose After surveying broadly the industrial environment, including its size and complexity, the new techniques and changes in materials and processes and in the work force, the Broadsheet considers the striking changes in the organization, direction and climate of the British economy since before the Second World War The social environment is then considered and then the implications of these developments are analysed in a section which points out that basic objectives proclaimed by the Unions only twenty-five years ago have now been achieved to a considerable extent and for a majority of working people, and much of the social and economic framework within which these original objectives were pursued has been remodelled

Nevertheless, the mood of the Unions is almost wholly defensive and conditions their attitude to change of all kinds. More particularly, it inhibits them from dealing with the specific difficulties of individual Union practice, organization and recruitment, which with the changing conditions have sometimes become out of date or hindered the appropriate changes The pronounced growth of the white collar and female sections presents other problems, as does structural decline in industries and regions where membership has traditionally been high Nor have the implications of the extension of higher education for the recruitment of able officials been faced.

One result of the failure of the Trade Union movement to discover and proclaim for itself any dynamic objectives in society to-day and to adapt its practices and organization to contemporary conditions is a growing public hostility to the Unions This is unfortunate in itself, and it tends to encourage unbalanced hostile comment in the newspaper Press, with a further consequence that the defensive attitude of the Unions is intensified and those elements in the movement who wish to prolong class struggle and distrust any advice from outside are encouraged The Broadsheet urges the need for better public relations, though it admits that this will depend to some extent on an improvement in the public performance of the Unions

It should be clear enough that, like the early studies which Political and Economic Planning has made of the Trade Unions, this further investigation is thoroughly sympathetic It recognizes that the traditional role of the Unions is still necessary and valuable, and it points out that, besides the functions of bargaining, settlement of disputes, consultations and communications, the Unions' capacity to provide workers with a sense of protection and community in the work-place, and especially in the modern, highly capitalized plant, is of great importance. Nor should the services rendered by the Unions in the way of friendly benefits and legal advice, or as spokesmen on matters concerned with social security, occupational safety and health, be overlooked The very importance of these continuing functions accentuates the need to eradicate weaknesses and adapt the Unions to perform these functions with efficiency, unity and authority

---

* *Planning*, 29, No 472, June 10, 1963 *Trade Unions in a Changing Society* By Bernard Donoghue, assisted by Janet Alker Pp 171-226 (London Political and Economic Planning, 1963) 5*s*

Even more important, perhaps, are the constructive suggestions made in the Broadsheet regarding the new functions and purpose of the Unions First, as regards fringe benefits negotiated voluntarily between Union representatives and employers, while British Trade Unions have hitherto shown less interest in these than their foreign counterparts, particularly in the United States, and in spite of some objections which can be raised to expanding fringe welfare, especially against benefits which supplement State provisions, it is suggested that there is a great opportunity for the Unions to adapt their practices and objectives The objections must be taken into account, but workers in general are highly conscious of a need for more security and higher standards of welfare

Next, the special situation and needs of women workers require attention, and here the Trades Union Congress is already taking a positive lead Again the provision of friendly benefits requires further study, and the Broadsheet makes several imaginative suggestions here To many workers a Union could offer a valuable service, for example, if it undertook to keep in touch with them after retirement, arranging home visits and providing social and holiday facilities This sphere of great and manifest need among old people has been comparatively neglected in contemporary society, the Broadsheet points to an opportunity which the Unions might well develop even if only among their own members

There are also opportunities for leisure work among the younger age groups, though these are perhaps overshadowed by the possibilities for Union provision in the field of education This is a subject in itself to which many people already consider the Trade Unions should give high priority, and devote fresh and original thought There is the question of special training for lay officers of the Union to equip them for the efficient execution of their duties In particular, the training of shop stewards is an issue of major importance and urgency, to which the Trades Union Congress and the British Employers' Federation have lately been paying close attention Plans for a joint campaign to stimulate co-operation between employers, Trade Unions and educational institutions to provide more courses for which stewards might be released from work with pay were announced in April

No less important is the larger question of education for the ordinary members as well as for the full-time officers It should be obvious that unless Union members are well informed regarding both the changing industrial and economic environments, positive attitudes and co-operation in planning and wage regulation, technological innovation, the abandonment of restrictive practices and so on, cannot reasonably be expected from them Such factors will be seen simply as a threat to their security and the underlying economic imperatives and the ultimate benefits to Union members will not be understood While it is now essential for the Unions to seek to protect their members in a constructive manner and without blindly opposing change, they must recognize that the only security of employment lies in the efficiency and competitiveness of British industry

Nor are these the only opportunities that confront the Unions They have responsibilities to minorities which are often overlooked, and at the national level there are economic objectives which can only be achieved with the co-operation of the Unions They could provide the institutional links between those who plan the policy and those who must ultimately work the policies, and harness the goodwill of the working community behind the objectives laid down as being in the national interest To do this they need not abandon any principles, though it would mean a change in the traditional conception of the role of Trade Unions and willingness to help promote, even to take the initiative in promoting, efficiency and economic growth

If the Unions are to do this, however, it is incumbent on the other parties, and especially the Government and the employers, to help by their own actions and examples in creating the conditions within which Trade Union reform can be facilitated Many people within the Trade Union movement recognize that changes in its structure and organization are desirable. It is important to strengthen their hand, to confront the movement with the fact that the reasons for change are related to its own future purpose and well-being and so to rally behind the reformers the large body of Trade Union members who are moderate and sensible but at present are sensitive to criticism, on the defensive and uncertain of what to do

Much of the analysis of the Broadsheet is supported by a section on the Trade Unions in a recent book, *Britain 1984 Unilever's Forecast*, in which Mr R Brech attempts to forecast the economic shape of the next twenty years He predicts a break-down of the big Unions into a number of small ones and the loss by the movement of much of the industrial and political power it has acquired over the past two generations Moreover, it is likely to be increasingly affected by the professionalization of the labour force and the growth of strong professional societies, covering engineers, scientists, mathematicians, statisticians and others While these may start as purely professional bodies they will increasingly take on protective functions

If Mr Brech's forecast is even approximately correct, it provides sufficient reason for the scientist and other professional workers to take a closer interest in the Trade Union movement in general Apart from the possibility just indicated of influencing that movement from within for the public good, the professional worker may sometimes be able to further that climate of opinion which the Broadsheet desiderates as essential for strengthening the progressive element within the Unions Nevertheless, the overriding reason for concern with the future of the Unions lies with the ordinary citizen

MASERS AND LASERS

Masers and Lasers

Molecular Amplification and Oscillation by Stimulated Emission By Gordon Troup Second edition (Methuen's Monographs on Physical Subjects) Pp viii+192 (London: Methuen and Co, Ltd ; New York John Wiley and Sons, Inc, 1963) 18s net

THE investigation of the interaction of radiation and matter received a significant stimulus about ten years ago with the practical demonstration of the first maser, a device which relies on the amplification of radiation by the process of stimulated emission. For some years the use of the maser principle was confined to the microwave region of the spectrum, where it has an important application in an amplifier with a very low noise temperature Recently the optical maser, or laser, has provided a source of radiation in the infra-red and visible regions

PHYSICS DEPARTMENTAL LIBRARY

with a degree of spectral purity, spatial coherence and power hitherto unachievable Apart from its numerous applications which are now being explored, the laser shows promise of giving a source of high power and narrow frequency range in the sub-millimetre or far infra-red where no such source at present exists

The first edition of Dr Troup's book was published in 1959 under the title *Masers*, and dealt exclusively with the microwave device The author was faced with the difficulty of writing on a rapidly developing subject, and with the necessity of keeping his treatment of the subject brief enough to fall within the compass of one of Messrs Methuen's well-established series of monographs The second edition, *Masers and Lasers*, contains essentially all the material of the first edition, in slightly revised and corrected form, together with additions describing the laser and its development up to January 1962 Apart from one chapter, which deals with principles common to all regions of the electromagnetic spectrum, only 16 pages are concerned with lasers

The theory of stimulated emission and related effects is approached both thermodynamically, following Einstein, and through quantum mechanics, maser action requires an inversion of population between two energy-levels, and the feasibility of producing such an inversion is later discussed The rest of the book is concerned mainly with a review of experimental methods and progress

As a treatment of the microwave maser, the book forms a most useful summary, which has benefited from the revision Although it was clearly the author's intention to cover both the microwave and optical regions of the spectrum he has confined himself largely to adding material to the first edition and has provided a work which is not so balanced a treatment as the title suggests Relaxation processes, for example, are discussed only in terms of crystalline solids, and there is no mention of equivalent effects in the gas discharge laser The only example of the relative magnitude of line broadening processes is, as in the first edition, the microwave transition in the ammonia molecule There are a number of other cases in which the original material has been retained unchanged in spite of the necessity for a broader treatment to include points relevant to lasers

The monograph is one of a series widely used by students who on meeting the subject for the first time might not detect some of the erroneous or misleading points which appear in this edition Among these are the use of the term "*Q*-factor *per unit length* of waveguide", an energy-level diagram of ruby, without further qualification, which is in fact only that of ruby at room temperature containing 0 05 per cent molar of chromium oxide, and the statement that the diameter of the discharge tube of the first helium–neon laser was 17 cm, instead of 17 mm There are also a few cases of confusing notation and inconsistencies which have arisen as a result of the revision of the first edition

The book can be thoroughly recommended as an introduction to maser principles and as a review of microwave achievements in this field The prospective reader should not, however, expect an equally full or lucid treatment of lasers J H Sanders

THE STATE OF PHYSICS

Physics in the Sixties

Edited by Prof S K Runcorn Pp vii + 112 (Edinburgh and London Oliver and Boyd, Ltd , 1963) 21*s*

To mark the completion of the new physics block at King's College, Newcastle upon Tyne, opened by Prof P M S Blackett, a series of lectures on aspects of physics was given Prof Blackett's speech touched on the development of physics in British universities

"Consider a moderately large physics department with an average of 100 undergraduates taking honours physics in each of three years, giving an undergraduate department of 300 Taking the present staff/student ratio as 1 . 7 or 8, as seems accepted as reasonable, there will be about 40 staff in the department Accepting further that 1 in 5 of the staff is a professor, there will be 8 professors. What should be the relation of these professors to each other and what part should they play in the three main functions of the staff—undergraduate teaching, postgraduate teaching and direction of research ?

"My own preference at present is on one hand for a completely unitary undergraduate teaching for a single unspecialized B Sc degree in which every member of the staff, including professors, takes part in the teaching And, on the other hand, for a number of research units with the maximum autonomy at postgraduate level In general, I think that every professor, if he wants to, should direct such a unit in our imaginary department there will then be about eight such independent research units with an average total of five academic staff each "

Each of the other chapters in the little book is the script of a lecture intended to be understood by the layman with some scientific knowledge or by scientists working in other fields The book should appeal to good sixth-form students who wish to obtain a background to their scholarship work in physics Prof L Rosenfeld, in a beautifully written chapter, traces the development of matter-force relationships from the days of the mythical Hermann Stoffkraft, a scientist less up to date, but as real as the mathematician N Bourbaki ! Sir John Cockcroft discourses on controlled thermonuclear fission, and gives warning of the tremendous difficulties, not realized in a premature over-optimism, which attend research work on this matter

Prof F Hoyle has a lecture on the origin of the solar system, in terms of recent work on nucleosynthesis, the relative abundance of a group of elements and modern knowledge of the origin of deuterons A D Garland writes on research on the Earth's interior, known as the 'Upper Mantle Project', C J Gorter gives an excellent short history of superconductivity and some possible future applications of low-temperature physics, and Prof R E Peierls rounds off the series with an essay on the state of physics, in which he deals, in particular, with the fundamental particles, the number of which increases in a manner which challenges the use of the word fundamental

The book, a readable and exciting little work, has been edited by S K Runcorn, professor and director of the Department of Physics, University of Newcastle upon Tyne W L Sumner

ELECTRONS AND ENGINEERS

An Introduction to Advanced Electrical Engineering

By C Jones (The Higher Technical Series) Pp x + 452 (London The English Universities Press, Ltd , 1962) 35*s* net

The number of books providing a link between elementary text-books on electrical engineering and advanced books on specialist subjects is somewhat limited, and this book is to be welcomed as an addition at a very modest price to the range available No claim is made for originality of material and no references are given to original papers There is, however, a list of books from which, it is to be presumed, most of the material for the present work was drawn

The book is mainly mathematical in its approach, and the standard is claimed to be that of a final-year for a first-degree course A student who had mastered its contents would compare favourably with the average student at the time of graduation The book can be safely recommended for the advanced student and is also likely to be of value to many lecturers for reference purposes The absence of numerical calculations and problems is a disadvantage which the author hopes to remove by the issue of a companion volume

The first chapter contains a useful summary of the mathematics required extending from elementary trigonometry to differential equations, Laplace transforms, conformal transformations and matrices It is too brief for any purpose other than to serve as a reminder of work learnt elsewhere Electrostatics, magnetism and electromagnetism occupy about one quarter of the book, and there follow separate chapters on electron ballistics, circuit theory, transients, symmetrical components, measurements and control systems The last chapter occupies more space than the three chapters given to electrodynamics and includes a useful section on magnetic amplifiers

The material is thus somewhat selective Machines are only mentioned incidentally in the treatment of servomechanisms Transformers are treated as a circuit element, and power transmission and distribution are treated as problems for circuit theory and symmetrical components Measurements are allotted only 40 pages, while valves are treated as a component for servo-mechanisms Transistors and rectifiers are not considered and although contact E M F is discussed there appears to be no reference to Hall, Seebeck, Peltier and Thomson effects

Selection is, however, essential in order to keep the size of the book within reasonable limits, and it might well be considered better to omit the chapter on "Measurements" altogether, since it is too short to do justice to the subject, in order to amplify the other sections A more serious criticism of the book is that the fundamental starting points of the subjects are too heavily condensed, sometimes to the point of inaccuracy For example, in paragraph (2) of Chapter 2 it is stated that a charge q produces an influence in space which can be observed experimentally This is not true Experimental observation can only be made of the reactions between charges Electric intensity is a mathematical conception which is convenient, but is not subject to observation The use of a unit charge for exploring the field is also unsound There is a similar confusion between experimental observation and mathematical conception in discussing magnetic fields The student would be well advised to obtain his ideas about the experimental basis of his subject from other books Maxwell is unbeatable in this respect, but for those who cannot bring themselves to look back earlier than this century, Jeans is to be recommended

One further omission must be referred to and that is the lack of a list of symbols or of adequate definitions of symbols Thus the symbol Z is introduced on p 188 for impedance without any definition Impedance is such a fundamental concept for circuit theory that this omission is difficult to understand

Once past the start, however the author's treatment is entirely sound and some of his mathematical solutions have an elegance which is not always found elsewhere

A H M Arnold

SKIN FRICTION AND HEAT TRANSFER FOR ROTARY FLOW

Hydrodynamic Resistance and the Heat Loss of Rotating Solids

By L A Dorfman Translated by N Kemmer Pp ix + 244 (Edinburgh and London Oliver and Boyd, Ltd , 1963) 63*s*.

THE engineer or scientist concerned with fluid mechanics and its applications is on the whole well served by existing text-books and monographs if his problems are those in which the motion of any solid boundaries can be regarded as rectilinear and the flow does not contain a major rotary component about an axis. However, for problems involving rotary velocity components and where the effects of viscosity are important the available books have generally provided little more guidance than a few references to scattered articles and research reports This is surprising, for these problems are not always particularly difficult and they can be of great practical importance They arise, for example, at various stages in the design and performance estimation of compressors and turbines, in the flow over propellers, in the cooling of electric motors and in the flight of rotating bodies To the theoretician they offer a rich field in which to find those rare gold nuggets of fluid dynamics—exact solutions of the Navier–Stokes equations

It is, therefore, fortunate and timely that Dr Dorfman has prepared this monograph on such topics (stimulated it seems by Prof Loitsyanskii), and this English translation by Prof Kemmer is particularly welcome

The book begins with a presentation without proofs of the basic Navier–Stokes equations and equation of energy for axially-symmetric flow of an incompressible, viscous fluid in laminar and turbulent motion The discussion continues with exact and approximate solutions for the laminar flow over an infinite rotating disk and includes the effects of a flow normal to the surface of the disk, of suction over the disk and some non-steady problems such as arise when the rotation of the disk is suddenly started or stopped A brief chapter follows on transition from laminar to turbulent flow on the rotating disk, this is based on the work of Gregory, Stuart and Walker, but the discussion of the theory is too scanty to be very helpful to the reader unfamiliar with this work. The disk with turbulent flow in its boundary layer, including the effects of surface roughness, is next considered, and this is followed by a discussion of the heat transfer at the disk surface with both laminar and turbulent boundary layers It is with these topics that the author's own research has been largely concerned Then follows a long chapter dealing with various problems of the flow around a disk rotating in a confined space, and it includes such topics as the effects of a parallel stationary disk, the effects of a cylindrical casing, the influence of roughness, leak effects and the flow between two rotating disks For such problems, the theories are almost always approximate (always so with turbulent boundary layers) and the comparisons with experiment that are presented are very welcome The following chapter is concerned with the flow and temperature distribution between rotating coaxial cylinders with the fluid both compressible and incompressible, and here in addition to the classical work of Taylor we find the results of some Russian work The final chapter deals with a rotating body of revolution in axial flow with particular reference to a rotating sphere

It will be seen that the author has confined himself to the basic topics that can be readily culled from existing sources and he has not attempted to make the book exhaustive It is largely but not entirely concerned with incompressible flow, and the rotating bodies considered are always simple such as disks, cylinders and solids of revolution This has given the author the opportunity to assemble his material in a logical sequence and the development is sensible and pleasing He has primarily aimed at presenting the essentials of the theories involved and he has not unduly stressed points of mathematical nicety and rigour The physical assumptions are generally clearly stated and he has presented comparisons of theory with experiment wherever the experimental data are available Any graduate who has already had a full undergraduate course in fluid mechanics or aerodynamics should have an adequate background for studying this monograph

Inevitably in a book of this kind with its emphasis on what the engineer calls 'working methods', the theories for turbulent boundary layers are semi-empirical and based on the simplest mixing-length concepts, however, a criticism which can be made is that these concepts are presented with no attempt at a critical assessment of their validity There are very few misprints and no obvious errors apart from a brief confused and confusing reference to the way in which the 'china-clay' method for observing transition works (p 43) A welcome feature of the book is the fact that the author has made use of and acknowledged the available important literature on his subject irrespective of the country of origin The printing, lay-out and diagrams are all very good, and Prof Kemmer is to be congratulated on the clarity and readability of the text, which betrays no evidence of being a translation This is a book that the engineer, scientist or research worker concerned with fluid mechanics and heat transfer will be glad to have ready to hand

A D YOUNG

WAVES AND SHOCKS IN PLASMAS

Waves in Anisotropic Plasmas

By Prof William P Allis, Dr Solomon J. Buchsbaum, and Prof Abraham Bers Pp xi + 280 (Cambridge, Mass The Massachusetts Institute of Technology Press, 1963) 57*s*

Magnetohydrodynamic Shock Waves

By Dr J Edward Anderson Pp xiv + 226 (Cambridge, Mass. The Massachusetts Institute of Technology Press, 1963) 6 50 dollars, 49*s*

THESE two books are respectively the seventeenth and sixteenth publications in the series of the Massachusetts Institute of Technology Press Research Monographs In each the many different types of wave possible within the framework of the analysis are investigated in detail, so that in one we find a two-dimensional diagram divided into 13 regions and, in the other, reference is made to a division into 52 regions of a five-dimensional space Both books are liberally illustrated with helpful diagrams and make excellent reference volumes

Waves in Anisotropic Plasmas is divided into two parts Part 1 on "Free Waves", by W. P Allis and S J Buchsbaum, and Part 2 on "Energy Power Theorems and Guided Waves", by A Bers Wave propagation is assumed to be of the form $\exp i\,(\omega t - \mathbf{k}\ \mathbf{r})$ in the presence of a static magnetic field, and linear equations are used throughout with the collision terms neglected soon after their introduction For much of the analysis the plasma is assumed to be temperate (thermal pressure gradients are neglected) so that waves of acoustic type are excluded, acoustic waves are, however, treated for the case of a scalar pressure in a separate chapter The most distinctive feature of Part 1 lies in the use made of (α^2, β^2) diagrams to discuss the different forms of propagation In these diagrams α is the ratio of the plasma frequency to the applied frequency, ω, and β is the ratio of the cyclotron frequency to ω, so that there are two values of β, one for the ions and one for the electrons If the product of these two values of β is now plotted against α^2, a diagram results in which various limiting conditions of resonance (where the phase velocity of the waves tends to zero) and cut-off (where the phase velocity of the waves tends to infinity) can be plotted as single distinct curves Thus the cyclotron resonances occur at two constant values of the ordinate and the plasma cut-off at a constant value of the abscissa ($\alpha^2 = 1$), while the cyclotron cut-offs and the plasma resonance occur as two smooth curves The set of limiting curves obtained by this means divide the diagram into 13 regions throughout each of which the propagation characteristics are broadly the same, and these the authors illustrate by means of small phase velocity diagrams inserted in each of the regions For further clarity coloured lines are used in some of these sub-diagrams A tribute to the informative nature of these diagrams is that Spitzer uses very similar illustrations (which he refers to as Allis diagrams) in the latest edition of his well-known *Physics of Fully Ionized Gases*

Part 2 deals with the propagation of power and gives a detailed field analysis of plasma wave-guides for the special cases of a static magnetic field imposed along and normal to the direction of the wave-guide The relations needed to transform the equations from the longitudinally magnetized to the transversely magnetized wave-guide are conveniently given in tabular form, and the rather complicated equations themselves are given by means of clearly laid out matrices This is in fact typical of the whole book in that emphasis is everywhere laid on the physics of the situation, and cumbersome algebra is avoided so far as possible

In *Magnetohydrodynamic Shock Waves* the author restricts himself to plane shocks which are collision dominated such that Hall currents are negligible and that the Navier–Stokes approximations are valid, relativistic effects are also neglected An investigation of possible discontinuities consistent with the relevant conservation laws (that is, the modified Rankine–Hugoniot relations) leads quickly to a set of equations connecting upstream and downstream parameters These are very effectively illustrated by means of three-dimensional plots for the three parameters, temperature, component of magnetic field parallel to the shock. and specific volume which by continuity is directly related to flow velocity In terms of these variables the equations are reduced to three in number which can be represented by surfaces of constant normal momentum flux, constant transverse momentum flux and constant stagnation enthalpy. two of these surfaces intersect in a curve which cuts the third surface in up to four points, any two of which (giving six possibilities in all) could represent conditions on either side of a shock These three-dimensional intersections can surprisingly be visualized quite easily with the help of the diagrams, perhaps this is just as well, because the reader has to accomplish a good deal of visualization before coming to the end of the book, and it comes as a relief at one point, much later in the book, to read "Because of the fact that this problem is five-dimensional, and hence impossible to visualize *in toto*, the discussion of slow shocks will be dropped at this point "

The principal aim of this monograph is at discovering whether magnetohydrodynamic shocks can be expected to occur in Nature, and this possibility is explored in detail by two methods The first of these, following Russian workers, is to investigate the stability of shocks with respect to small disturbances In this section a small amplitude wave is supposed to disturb the shock, and the resulting reflected and transmitted waves are investigated with regard to their energy content Boundary conditions are available at the shock for determining the strengths of the diverging waves, but for some types of shock they are insufficient in number so that infinitely many solutions to the small-wave problem are possible The interesting conclusion is drawn that these shocks are non-evolutionary, and if they were to exist at any instant they would rapidly break up by spontaneous emission of waves Switch-on and switch-off shocks (where the magnetic field component parallel to the shock is zero before and behind the shock respectively) do not belong to this category but are nevertheless found to be limiting cases where the energy carried away by the diverging waves tends to infinity, so that it is concluded that these shocks are unstable to certain wave disturbances This conclusion will no doubt lead to much controversy as indicated in the short appendix by W H Heiser, which describes an apparently successful attempt to observe switch-on shocks in the laboratory, although this of itself does not contradict Dr Anderson's conclusion since there is no reason to suppose that the shock would meet the required destabilizing disturbance during its short life-time in a shock tube In later chapters of the book, the shock layer is investigated directly from the differential equations of flow through the shock, and again the treatment is of great interest, although rather involved, with results that support those of the stability investigations Apart from the existence investigations which occupy much of this part of the book, close attention is given to the order of magnitude of the terms in the differential equations and it is shown that some terms, such as the electron pressure terms, which have been neglected by previous authors, can in fact be important

Dr Anderson keeps the physics of the problem well to the fore, and for the most part the mathematics is clearly presented E G BROADBENT

NATURAL FIBRES

Vegetable Fibres

Botany, Cultivation and Utilization By R H Kirby (World Crops Books) Pp xvi+464+54 plates (London Leonard Hill (Books) Ltd , New York Interscience Publishers, Inc , 1963) 84*s*

DESPITE the fact that vegetable fibres have been, and undoubtedly will continue to be, of the utmost importance to mankind, few comprehensive general reference books have been published on their botany, cultivation, and production Apart from Matthews (Mauersberger), sixth edition, 1956, which deals, necessarily briefly, with this subject as one section of textile fibres, in general, one has either had to search the literature, or else to consult more narrow specialist texts (such as Haarer, 1952) or older publications (for example, Goulding, 1919)

The appearance of Dr Kirby's excellent book comes at a time when large masses of the world's population are arriving at self-government and must realize, inevitably, the importance of husbanding their natural resources in the production of wealth Among these, vegetable fibres of all types can play a valuable part Not only does this book provide an easy means of acquiring technical information its recognition of the importance of economic factors is also most commendable Apart, therefore, from students of textiles and agriculture, etc , it will be consulted by textile interests at executive policy-level and also by those entrusted by Governments with the economic development of this aspect of agriculture

The subject-matter is well classified into botanical families and deals mainly with plant cultivation and fibre production, and to a lesser extent with botanical matters In addition to flax, hemp, jute, *Hibiscus* sp , ramie, sunn and Mauritius hemp, sisal, New Zealand flax, manilla, coir, etc , a large number of lesser-known fibres are discussed in detail The chapter on the mechanical production of stem fibres is a stimulating introduction to modern practices which may have to play a vital part in the future The very great difficulties of handling, expeditiously and economically, large masses of fibre-bearing material, in which the valuable fibre content may only be small, the difficulties of imitating, mechanically, actions which appear to be so easily, albeit laboriously, done by hand, and the delicate economic balance between mechanization on one hand, and peasant production on the other, are all realistically assessed It is obvious that the author, who has visited fibre-producing areas all over the world, writes very much from first-hand knowledge

It is to be expected, however, that a publication of this type, in which one author deals with so large a field, is unlikely to be free from criticism, more especially in those sections where information is probably second hand The comparatively scant attention paid to 'utilization' suggests that this term might have been inferred rather than meriting inclusion in the title Why, for example, is jute, second only in bulk importance to cotton, and also flax, given only a few lines compared with two pages for ramie, a comparatively unimportant fibre ?

It is unfortunate also that clear line-drawings could not have been included of the bast fibre lattice work and its positioning within the stem and also drawings or clear photomicrographs of the ultimates within the fibre bundles of most of the fibres instead of only one or two In general, also, the many photographs of decorticating, ribboning and other machinery are not good, except possibly in a pictorial sense, for unlike line drawings they do not clearly illustrate how the machines work In a reference book, clear tabular presentation of statistics is to be expected It is to be regretted that many useful data are scattered, not very systematically, throughout the text, a drawback which will not appeal to the business executive It would have been helpful if the admirable costing flow-sheets, presented on p 189 for sunn hemp and on p 214 for kenaf, could have been repeated for some other fibres

In Chapter 1, and elsewhere, some erroneous generalizations exist Thus, tensile strength is not necessarily the most common test to which fibres are submitted (p 8), not all fibres are affected by moisture in their physical properties (p 8), the cementing matter holding the ultimates together in the fibre bundle is by no means always pectinous (p 11), nor are all fibres sprayed with lubricants or oil during processing (p 13) It is not necessarily true, in all aspects of vegetable fibre usage, to claim that the higher the cellulose content the more valuable the fibre (p 10) Retting is not the most important operation for all fibres (p 21), many are won from their natural setting by mechanical means only During the Second World War, so-called natural or mechanically decorticated-unretted flax was used without de-gumming by the dry-spinning industry, which did not find it stronger or superior to retted fibre (p 35) What are 'strong' chemicals (p 10) ?

Greater reference might also have been expected to be made to the considerable experience gained and research done by the U K Flax Advisory Committee in all phases of flax cultivation, retting and production etc , during the Second World War, some of which was published in *Quality in Flax* by A J Turner (1954)

Apart from these minor criticisms, however, this book is of undoubted merit well printed, well-bound, and carefully indexed, with an extensive bibliography, it is assured of wide demand H L PARSONS

A HAND-BOOK OF THE LARGER FUNGI

Collins Guide to Mushrooms and Toadstools

By Morten Lange and F Bayard Hora Pp 257 (96 plates) (London Wm Collins, Sons and Co , Ltd 1963) 30*s*

JAKOB LANGE'S magnificent coloured plates of toadstools in his *Flora Agaricina Danica* have long been among those most valued by specialists in European Agaricales It was, therefore, a happy thought on the part of his son to make a selection of them available on a reduced scale, two-thirds the size of the originals, to a much wider audience, in the form of a cheap popular hand-book dealing with the larger fungi A few plates of the more conspicuous Ascomycetes, Gasteromycetes, Boletes and Aphyllophorales have been supplied by other hands, but it must be admitted that some of those depicting polypores are much less successful than those of agarics by J Lange Sometimes, even with the latter and with Boletes the colours as reproduced scarcely bear out the brief descriptions printed opposite each plate Oddly enough, the figure of *Laccaria proxima*, duly shown with elliptical spores in the Flora, is here reproduced as *L laccata* and said to have globose spores In the Flora, essential microscopic details, especially of spores and cystidia, were indicated on the plates by line-drawings beside the coloured illustrations One wonders why these have been omitted from the present work The authors must know that a considerable proportion of the species depicted cannot be identified with certainty by macroscopic characters alone, even the generic key provided cannot be worked without reference to some microscopic details To overcome this difficulty spore dimensions and other microscopic features are quoted briefly after the entry of each specific epithet in the index. Some characteristic basidiospore shapes are drawn in Figs 11 and 12 on p 230, while some rather crude sketches of cystidia appear in Fig 9 on p 228 This appears to be a valiant effort by the English editor to overcome a radical defect of the original Danish edition

Because there was no such cheap and reliable hand-book covering the same field available in English, one must be grateful to the authors and publishers for their enterprise The colour reproduction is reasonably faithful on the whole, and such blemishes as do occur have probably to be accepted as inevitable if so many coloured plates are to be offered so cheaply in these days of expensive book production Anyone tempted to use the book for identification of species in serious ecological or floristic investigations should remember, however, that it figures scarcely a quarter of the species of Basidiomycetes known to occur in the British Isles and that many of the omitted species are superficially not so very different from some of those illustrated Identifications to be placed on record should, therefore, be checked by reference to the more critical works listed in the bibliography or be verified by a specialist while the collections are in a fresh condition

R W G Dennis

LEECHES

Leeches (Hirudinea)

Their Structure, Physiology, Ecology and Embryology
By K H Mann With an appendix on the Systematics of Marine Leeches by Prof E W Knight-Jones (International Series of Monographs on Pure and Applied Biology Division Zoology, Vol 11) Pp viii+201 (London and New York Pergamon Press, 1962) 45s ; 7 50 dollars

DR K H MANN is to be congratulated on this excellent book The leeches or Hirudinea are not a well-known group of animals indeed, biology students normally come out of university knowing very little about them This regrettable state of affairs can now be remedied for here is presented, for the first time, a comprehensive survey of this small, though important, order of the phylum Annelida designed for use by students, teachers and research workers

The medicinal leech *Hirudo medicinalis*, is taken as a type and, with meaningful text and a selection of first-class diagrams, its morphology and histology explained with exceptional clarity Then the latest knowledge of leeches is analysed to delight the physiologist, behaviourist, ecologist, and systematist alike A survey of the group introduces the reader to the wide range of form encompassed in the Hirudinea, and chapters on nutrition, excretion and water balance, circulation and respiration; muscle, nerve and locomotion; sense organs and behaviour, reproduction and development, and ecology, continue a delightful zoological story

Finally, there are two appendixes on the systematics of the group The first of these, by K H Mann, on fresh-water and terrestrial leeches includes diagnoses from sub-orders to families and illustrated keys to species from Central Europe, Britain and North America The second, by E W Knight-Jones, provides a key to marine genera of the world, diagnoses of North Atlantic genera and species, with a host list

Extensive use will be made of this gem of a book by all zoologists interested in the invertebrates It is especially recommended to teachers as a source for new adventures by their pupils, for "leeches are fascinating animals, full of strange zoological paradoxes" Norman Tebble

TAXONOMY OF TIMBER BEETLE LARVÆ

A Monograph of the Immature Stages of Australasian Timber Beetles (Cerambycidae)

By E A J Duffy Pp vii+235+11 plates (London Printed by order of the Trustees of the British Museum (Natural History), 1963) 105s

TWO major difficulties beset workers in the field of larval taxonomy, especially those who, like the author of *A Monograph of the Immature Stages of Australasian Timber Beetles*, deal with large groups on a regional basis. First, museum collections of identified larvæ are usually poor or non-existent, and the worker must depend heavily on the assistance of resident entomologists in those countries which he himself often cannot visit Secondly, few such investigations are likely to be complete, and taxa must be defined on the basis of less-extensive material than is available of the adult stage The industry of Mr Duffy—and his ability to elicit co-operation—are made evident by the excellent coverage of this first review of the immature stages of the Australasian Cerambycidae.

All sub-families represented in the region are characterized in terms of both larval and pupal structures Descriptions of, and keys to, the late-stage larvæ of 100 species are provided, these are representative of 77 genera contained in 43 tribes, more than half the tribes known to occur in the region The pupæ of 44 species are similarly treated Records of host plant are given for some 250 species There are also excellent summaries of bionomic data (including much previously unpublished), and of the control methods used against species of known economic significance in forestry The stated aim of the monograph is to provide a means of identifying the immature stages of these insects The lucid keys and descriptions, supplemented by very good drawings and photographs, should fulfil this purpose admirably

In his earlier monographs of the immature Cerambycidae of the Palæarctic and Ethiopian Regions, Duffy was able to select "single fundamental characters" that defined the higher taxa, and to arrange keys that placed these taxa in "the generally-accepted sequence of adult classification". In his review of the Neotropical fauna, and in the present work, neither of these aims was realized fully Some taxa could be defined only in terms of different combinations of the same or similar characters Larvæ often exhibited such morphological heterogeneity that portions of the same taxon had to be brought out in remote parts of the key Such results inevitably place in question the validity of phylogenies deduced from morphological characters of the adult stage alone It is interesting to note that, due to divergences of larval characters, Duffy found it appropriate to elevate to sub-family rank three taxa that are traditionally given tribal status

The *Monograph* will prove of very great practical value to forest entomologists in Australasia, and represents a notable addition to Duffy's series of publications in this field His next volume, on the Cerambycid fauna of the oriental region, will be awaited with interest

The printing, format and binding are of that most pleasing quality one has come to associate with the British Museum (Natural History) monograph series

P. B Carne

The Annual of the British School at Athens

No 57, 1962 Pp xii+242+53 plates (London The British School at Athens, 1963) 105s net

THE 1962 *Annual of the British School at Athens* is dedicated to the great British epigraphist, Marcus Neibuhr Tod, thus it is that of twelve articles on Greek archæology five are concerned with inscriptions The most substantial, by L H Jeffery, is on "The inscribed gravestones of archaic Attica" Miss Jeffery provides a detailed catalogue of these inscriptions, establishes between six and ten masons operating in the sixth century B C and briefly puts together what is known of the named sculptors of this period Of the other epigraphical contributions, Daphne Hereward publishes ten Greek inscriptions from the Khersonese and P M Fraser "Two Dedications from Cyrenaica", the first showing religious links between Cyrenaica and Crete, the second between Cyrenaica and Samothrace The other two articles use inscriptions to demonstrate historical theses, that by D M Lewis to show that the Island of Keos possessed a federal constitution in the first part of the fourth century B C, that by A M Woodward to show connexions between the famous oracle of Ammon in the Libyan desert and the establishment of a sanctuary of Ammon at Athens, also in the fourth century B C

There are two site publications Jones, Sackett and Graham publish their excavation of the Classical house lying near the Aigaleos-Parnes wall, north-west of Athens and used for a very short period, about 420–410 B C The article contains much meticulous information on Classical Greek houses, and relates this house to the standard publications of those at Olynthus and Athens The other site is the Byzantine basilica church at Knossos in Crete, built early in the sixth century A D on top of an earlier Christian cemetery extending back perhaps as far as 200 A D This excellent publication of Frend and Johnston (with fine photographs of the mosaics) throws light on a little-known period of Cretan history and relates the Knossos basilica church to others in the Island

Of the other contributions, D M Metcalf gives a study of Byzantine history in the Aegean from coin hoards of Heraclius I (610-641), J Boardman publishes miscellaneous finds of the seventh and sixth centuries B C from Knossos, and D M Bailey the Greek and Punic Lamps from Tharros in Sardinia The only prehistoric articles this year are by John Chadwick with "Further Linear B tablets from Knossos" and by Hope Simpson and Lazenby with another of their topographical studies, this time of various islands in the Dodecanese PETER WARREN

Neutron Diffraction

By G E Bacon Second edition. (Monographs on the Physics and Chemistry of Materials) Pp xii+426 (Oxford· Clarendon Press, London Oxford University Press, 1962) 55s net

THE use in research in solid-state physics of the powerful method of neutron diffraction dates from about 1950, when, with the advent of nuclear reactors, intense beams of neutrons became available Neutron diffraction complements and supplements X-ray diffraction, and has particular applications in the study of magnetic and molecular structures and the lattice dynamics of crystals

Prof Bacon ranks as a pioneer and as a leading authority in the construction and use of neutron diffraction apparatus When the first edition of his monograph appeared in 1955 it was the first comprehensive text-book on the subject The wealth of unique practical experience described in it and the important information that the use of the method had obtained or was capable of obtaining soon spurred others to make use of the technique, and it is therefore not surprising that the second edition quotes some 500 instead of 300 references to published work

The main structure of the first edition has not been altered. The monograph is still divided into two parts The first chapters—now with the addition of a chapter on inelastic scattering—deal as before with the physical principles of neutron diffraction, the experimental methods, and the determination of fundamental data for structural investigations The remaining nine of the sixteen chapters in the second edition discuss the increasing number of applications of neutron diffraction, in the determination of the atomic positions of light elements, the study of molecular structure, the investigation of magnetic materials, and the examination of diffraction by gases, liquids and amorphous solids The sections in the first part have been revised and brought up-to-date, and much of the second part has been re-written to conform with the great increase in application of neutron diffraction during the seven years between the two editions

The monograph is excellently produced, and the text and diagrams are easy to read It is the standard and authoritative text-book on the subject of neutron diffraction, and it is warmly recommended to the honours physics undergraduate and to the research worker who are interested in the atomic architecture of materials, whether physicist, chemist or metallurgist.

S WEINTROUB

Encyclopedia of Chemical Technology

Vol 1 A to Aluminium By Kirk-Othmer Pp xix+990 (London and New York John Wiley and Sons, Ltd, 1963, second edition, completely revised) 260s per volume for subscribers to the complete set of 18 volumes.

THE first edition of "Kirk-Othmer" in fifteen volumes published between 1947 and 1956 has won international acclaim for the authority of its information and amply fulfilled the original editors' intention of presenting the entire field of chemical technology for professional chemists and chemical engineers who wish to know about specialized practices and materials, particularly outside their own immediate experience The editorial board has now embarked on the publication of the second edition, which, they claim, is more than a mere revision of the first All the technological articles have been rewritten, some by the same, some by a different, author Each author is a specialist and each article has been reviewed by one or more other specialists

The first edition concentrated on presenting United States technology, the second is to contain contributions from other countries This is most welcome, particularly if it leads to the inclusion of European trade names and chemical specifications, the lack of which was a drawback to British readers seeking comparisons between American and European products

The new volume contains forty-six articles They range from "Abherents", a more sophisticated term for release agents used in moulding, casting and baking, through "Ablation", which is concerned with the re-entry problems of missiles, to "Aluminium", where mention is made of the new carbothermic and reduction-distillation processes now being studied in France and Canada The article on "Alkyd resins" reflects the changes in the meaning of the term since the first edition was written "Acetate and triacetate fibres" have been separated from "Rayon", and a useful, though not over-extensive, survey of the aerosol industry is included He who seeks information on industrial alcohol must now wait for "Ethanol" to appear

Changes in format are minor An index is not provided, but those readers fortunate enough to have access to and experience of the first edition should be able, by judicious comparison of the two editions, to overcome this drawback to a large extent

The first edition appeared over a ten-year period The editors propose a similar schedule for this enlarged edition W D MANIECE

MONKS WOOD EXPERIMENTAL STATION

By Dr. KENNETH MELLANBY, C.B.E.

Director

MONKS Wood Experimental Station of the Nature Conservancy was officially opened by Lord Hailsham, Minister for Science, on October 28 [see following article]. It is the first research station in England specially built by the Conservancy for scientific research.

The buildings cover some 25,000 sq. ft. They are mostly single-storey laboratories, but there are also a library, lecture room, canteen and hostel block. The tower, which, though only about 50 ft. high, dominates the rather flat Huntingdonshire countryside, is essentially a water tower (needed to ensure adequate pressure in the laboratories), the space below the tanks being used to produce fourteen study-bedrooms for postgraduate students working at the Station.

The architect, Mr. K. A. Poole, of Messrs Cowper, Poole and Partners, has endeavoured to design a building which is functional and yet fits into the traditional pattern of the area. The brickwork is similar in colour—a pale yellow—to that found in many eighteenth- and nineteenth-century buildings in Cambridgeshire and Huntingdonshire. The laboratories are constructed from a series of units, 11 ft. × 22 ft., which has allowed flexibility in design and economy of construction. Unlike many recent buildings, the rooms have their main windows at the narrow end, and the benches are all at right angles to the windows. Additional illumination at what would have been the dark end of the room is obtained by a clerestory window, made possible by the lower level of the roof of the central corridor. The services run in the corridor roof and in the vertical members between the 11-ft. units. Laboratories of one or two units are provided, and folding doors in the library/lecture room allow meeting-rooms of various sizes, up to one which can seat nearly three hundred, to be made. Although the standard of the building work and of the laboratory fittings is good, this has proved to be, for to-day, an economical building, costing not more than about £4 per square foot of floor space.

The Station houses three research sections. They are all engaged in work concerned with the Conservancy's function of controlling and preserving the flora and fauna of Britain, and in giving scientific advice on conservation. Monks Wood is called an "Experimental Station" because it will tend to concentrate on research in applied ecology rather than on the long-term fundamental research carried out in other Conservancy stations, and is thus intended to serve as a link between the Research and Conservation Branches. However, rigid demarcation is not always possible or desirable, and fundamental aspects of conservation will obviously be tackled where necessary.

The Station has some 70 acres of arable land attached which will be used for experiments. Already some miles of hedges have been or are being planted, and some plots for work on soil fauna have been laid down. There is a meteorological station which keeps records of the temperature, including that at several depths in the soil down to 4 ft., rainfall, etc., and a 'potential evapotranspirometer' fits into the series maintained by the Conservancy in many parts of Britain, to contribute to the study of the country's water balance.

Work will be done where most appropriate in all parts of Britain; but when possible travelling will be kept to a minimum. The Station is now responsible for the management of the National Nature Reserves of Monks Wood (387 acres of mixed woodland actually adjacent to the laboratories) and Woodwalton Fen (514 acres of fen and marshland, about three miles away as the crow flies). Not all experiments can be performed on National Nature Reserves, where conservation interests must be paramount; but the programme should help rather than hinder the preservation and diversity of the flora and fauna.

The Conservation Research Section is under Dr. E. Duffey, who was previously regional officer for East Anglia, and is thus very familiar with the practical work of the Conservancy. This Section hopes to do research into Nature reserve management, and to build up a store of ecological knowledge which will be available to organizations responsible for wildlife conservation. Field work at present consists of investigations of the invertebrate fauna of open-ground habitats, mainly grass heaths on sand which include many important Nature reserves; the management of chalk grassland to preserve floristic richness, and a study of fen problems, particularly aquatic fauna, at Woodwalton Fen.

Dr. J. D. Ovington is head of the Woodland Research Section. He was formerly at the Conservancy's Station at Grange-over-Sands, where he investigated woodland productivity, work he also developed in the United States. This Section carries out research on the productivity of the woodland ecosystem, and is responsible for giving advice to the Conservancy regional staff on the management of the woodlands in some 56 National Nature Reserves. They produce working plans for the reserves when this is necessary. Woodland is the natural plant cover over most of the land surface of Britain, so woodland research has an important part to play in all reserves, even in those where trees have to be discouraged.

The Toxic Chemicals and Wildlife Section is under Dr. N. W. Moore, formerly regional officer in South-west England and a lecturer in the University of Bristol. This Section was set up to examine the effects of pesticides

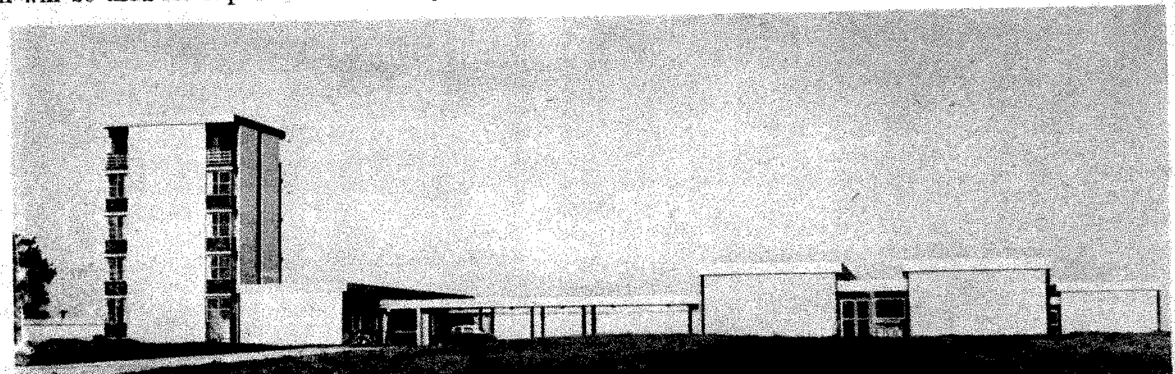

Fig. 1. Monks Wood Experimental Station, Huntingdonshire

on wildlife, and to advise governmental and other bodies on this subject. Its work has had the most publicity, owing to the widespread concern about the possible misuse of toxic substances. The Section, like the rest of the Station, is primarily interested in conservation, but particularly in the way new hazards (due to persistent and poisonous substances) may affect conservation. It is carrying out background investigations on wildlife habitats affected by pesticides, for example, examinations of the flora and fauna of hedges. Surveys of the distribution of persistent insecticidal residues in wild populations are in progress. These investigations are showing that residues of organic chlorine insecticides are widely distributed in terrestrial, freshwater and marine habitats, and that predators contain higher residues than other animals. Field experiments on the effects of pesticides on the flora and the invertebrate fauna have been started, particularly dealing with soil inhabiting species. The Section also includes an information service which acts for the Committee on Ecological Effects of Chemical Controls of the International Union for the Conservation of Nature and Natural Resources.

The Nature Conservancy has always believed that it has an important role in education, and that this must be exploited if conservation and the understanding of wildlife problems is to be successful. Monks Wood has been designed to play its part in education at several levels; in particular, it will be concerned with the postgraduate diploma course in conservation, run by University College, London. The residential accommodation was planned primarily to house these students, who will spend a substantial part of their year doing field work in the neighbourhood. A laboratory has been set aside for them and other visiting workers. Plans are well advanced for a residential course for some of those taking the diploma in technology in applied biology, and various other classes and seminars are under consideration. The recommendations of the Robbins Committee, that there should be close contacts between universities and research establishments, is welcomed by the Conservancy and the Station. Monks Wood will, I hope, make a contribution to many aspects of postgraduate and other training, and will thereby benefit from the inspiration which research can receive from teaching and from contact with students.

EFFECT OF TOXIC SUBSTANCES ON WILD LIFE*

By THE RIGHT HON. VISCOUNT HAILSHAM, Q.C.†

Lord President of the Council and Minister for Science

I FIND that most people are still unaware of what the Nature Conservancy is; rather vaguely they seem to associate it with the National Parks and seem to think that the Nature reserves we have established are primarily there for the purpose of recreation.

The Nature Conservancy is a scientific organization concerned with the scientific study of our environment—ecology, to use a more technical term. It can achieve its purpose only by acquiring and retaining the goodwill of all those who own, work in, enjoy, and otherwise use the countryside.

Monks Wood will be the centre for applied ecological research undertaken by the Conservancy. It will help to bridge the gap between the long-term fundamental work carried on at other establishments by the Conservancy and its practical application in land use problems. Monks Wood will also be used for the training of postgraduate students in ecological subjects. I have always attached great importance to close working contacts between Government research establishments and university departments. The staff and excellent facilities at Monks Wood enable it to provide systematic and properly supervised courses for postgraduates. Development of postgraduate studies along these lines is fully consistent with the Robbins Report.

Of the three scientific activities going on at Monks Wood—conservation research, woodlands research, and research into the effect of toxic chemicals on wild life—I shall refer to the third only, not necessarily because it is the most important, but because it is the most topical, and because there are things about it which the public should bear in mind.

The first is that this is a particular aspect of a general problem which concerns me as Minister for Science at several different points, and concerns several different Ministries in three or four different ways.

The second is that it tends to be a subject which arouses strong emotion, and strong emotion is bad for scientific judgement. The scientific evidence, which is voluminous, justifies almost any opinion other than extreme ones, and those who hold extreme positions on either side must get used to the view that they are not supported by the scientific evidence, although they may seek to express their opinions in scientific, or pseudoscientific, language.

The third is that, quite apart from the scientific evidence, the practical judgement in favour or against the use of toxic chemicals in agriculture must be one of balance and caution. I am not prepared to back scientific farming absolutely if it results in the widespread destruction of wild life, particularly if it threatens whole species. I am not prepared to favour the conservation of wild life absolutely against scientific farming.

There are also two particular facts to be borne in mind. The first is that people are apt to forget how much recent effects on the destruction of bird life were the result of the indiscriminate use of a particular group of chemicals, the dangers of which are now appreciated and which are now more effectively controlled. The second is that the defences mounted by the Government in that particular case are as much an example of the effectiveness of our defences—of which an important element is the Nature Conservancy—as of the dangers of the chemicals.

On one thing we can all agree and that is the importance of continuous research. This is the value of Monks Wood, and of various other stations and units of the Nature Conservancy, the Agricultural Research Council, the Medical Research Council, the Department of Scientific and Industrial Research and the Departments of Agriculture. It is not a question whether enough research is being done. The point is that the research will have to be continuous and ever changing precisely because the problem is a continuous and changing problem. This is why I have Prof. A. C. Frazer's Committee keeping research in this field under continuous review and advising me so that the Government can ensure that our research effort is meeting changing needs. The use of chemicals in agriculture is only a special case of a much wider question: the use by mankind in almost every field of his activity in this technological age of increasingly powerful substances the effects of which are sometimes unexpected, occasionally dramatic and often undesired.

This is a question which cannot fail to attract the attention of Government in a variety of different ways, and it is worth while admitting at the outset that no Government can claim to have discovered absolute answers to all the questions. Nor will it ever do so, because the nature of the dangers will continually change with the change in technology and science. What is wanted is not an absolute answer but a proper means of watching issues as they arise and a proper organization for ensuring that scientific opinion influences policy at a sufficiently early stage. By far the most dramatic and tragic recent case of this general question was the side-effects of thalidomide on the human fœtus; but it would not be difficult to find examples of many kinds in industrial medicine or public health or, for that matter, in nuclear physics.

---

* Substance of an address delivered at the official opening of Monks Wood Experimental Station, Huntingdonshire, on October 28 (see *Nature*, 190, 488; 1961; and preceding article).

† Now the Right Hon. Mr. Quintin Hogg, Q.C.

There is, in fact, practically no way in which man has not altered his environment. It is one of the permanent and serious dangers of a scientific and technological society and one against which a scientific and technological society must learn to erect substantial defences. We cannot have the benefits of science and technology without running some of these risks; but in applying new knowledge we cannot do so responsibly unless we make some insurance against the risks. What we cannot hope to do, however, if we are to accept the benefits of a scientific and technological society—which I believe it is the overwhelming desire of the people of Britain and, indeed, of the whole modern world to do—is to guarantee that there will never be any unexpected or evil side-effects on wild life, human beings, and domestic animals and crops. In some cases these results will appear only after the greatest possible care has been taken, after they have been applied over a long period of time and over a wide population or considerable area.

This means, so far as wild life is concerned, the Nature Conservancy; so far as the interests of agriculture are concerned, the Agricultural Research Council; so far as human life is concerned, the Medical Research Council; and so far as industry is concerned, the Department of Scientific and Industrial Research; and finally, so far as the balance of public advantage is concerned, the Minister for Science must hold a watching brief to see that scientific opinion is continuously directed to the relevant questions, and that public opinion is constantly advised about the biological consequences of a technological age.

I wish to pay my own tribute to the staff of Monks Wood Experimental Station, who have been pushing ahead with the aid of a certain amount of improvization before the building was completed, and to the people and organizations who have shown their willingness to help. I must also thank, on behalf of the Nature Conservancy and my own behalf, the University of Cambridge, Lord Iveagh, Lord de Ramsey and other landowners who have generously provided facilities for research. A number of private firms have also helped with information and facilities. The work of Monks Wood, and indeed of many research establishments, depends for its success on good relations and close links with universities, landowners and industry.

NEW PERSPECTIVES IN BIOLOGY

By Prof. JOHN T. EDSALL
Biological Laboratories, Harvard University, Cambridge, Mass.

A NOTABLE symposium on new perspectives in biology was held at the Weizmann Institute of Science, Rehovoth, Israel, during June 10–17, to celebrate the inauguration of the Ullmann Institute of Life Sciences (Fig. 1). A distinguished group of biologists, biochemists and biophysicists, from Europe, from the United States, and from Israel, presented papers on the present state and future prospects of many fundamental problems in biology, and carried on informal discussions together for a week.

We may recall briefly the history of the Weizmann Institute. Its forerunner, the Daniel Sieff Research Institute, was dedicated in 1934, and formally opened by Dr. Chaim Weizmann, who played an active part in its development. Expansion of the Sieff Institute was conceived in 1944, when a group of Dr. Weizmann's friends wished to honour his seventieth birthday, and the Weizmann Institute was formally dedicated by Dr. Weizmann in November 1949. It has since grown to comprise eighteen research units, covering a wide range from applied mathematics and theoretical chemical physics to genetics and cell biology. It includes a graduate school, with about 115 students working for the Ph.D. degree. Its contributions in many areas have exerted a profound influence, and visiting scientists have gone to work there from all over the world.

The Ullmann Institute of Life Sciences, which was dedicated at the beginning of the symposium, on June 10, fills an urgent need of the Weizmann Institute. Workers in biochemistry and in many aspects of biology have been carrying on distinguished research in increasingly cramped surroundings, as numbers and activity grew. The Ullmann Institute, given by Siegfried and Irma Ullmann, of New York, will comprise research units of biochemistry, biophysics, virology, and genetics, in much ampler quarters and with exceptionally fine research facilities.

The dedication of the new Institute, held in the open air, close by the building itself, in the late afternoon light, was an impressive and moving ceremony. David Ben Gurion was there to offer greetings on behalf of the Government of Israel; it was one of his last official acts before his unexpected resignation a week later. Amos de Shalit, director of the Weizmann Institute, and Ephraim Katchalski, who will play a leading part in the Ullmann Institute, spoke briefly of what this new development will mean. Mr. Ullmann warmly replied, and Mrs. Ullmann then formally opened the new laboratories. An air of genuine dedication, not usually felt in such ceremonies, pervaded the whole event. Israel is a country where men have achieved much in a few years, against great odds. The growth of the Weizmann Institute into one of the world's great research centres, within so short a period, was one manifestation of this. Here was one further achievement, leading to still greater activity in the future.

Immediately thereafter, Jacques Monod (Pasteur Institute) delivered the opening lecture of the symposium on the role of allosteric effects in the control of cellular metabolism. These involve the transmission of inhibiting, or sometimes of activating, effects from one region of an enzyme molecule to another, the inhibiting agent representing generally the final product of a metabolic pathway, whereas the enzyme catalyses the initial reaction in that same pathway. The profound biological significance of these mechanisms is clear; Monod and his colleagues, J.-P. Changeux and F. Jacob, have recently provided an admirable review (*J. Mol. Biol.*, 6, 306; 1963).

The following morning session was devoted to proteins, beginning with a survey of important current trends in present-day protein research by J. T. Edsall (Harvard), followed by a discussion by J. C. Kendrew (Cambridge) of the detailed structural features of myoglobin and hæmoglobin, their implications for protein structure in general, and the prospects and difficulties of further explorations of protein structure by X-ray crystallography. H. Neurath (University of Washington) dealt with the structure and function of proteolytic enzymes, and particularly with

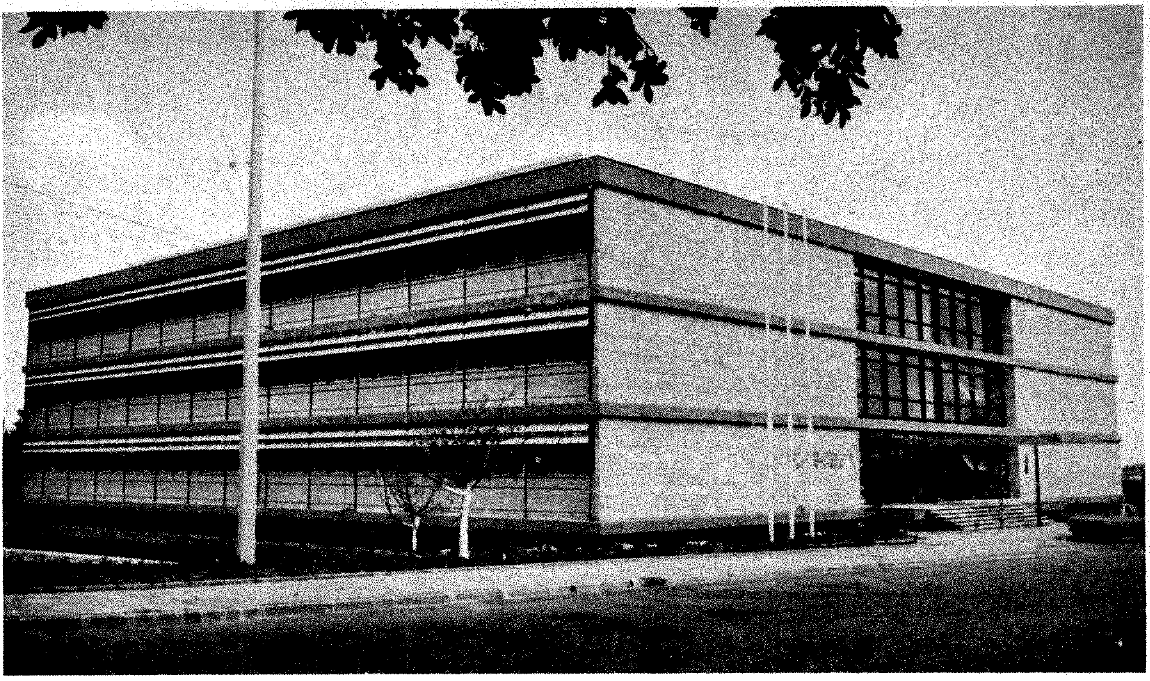

Fig. 1. The Ullmann Institute of Life Sciences, Weizmann Institute of Science, Rehovoth, Israel

the recent remarkable findings in his laboratory involving the activation of pancreatic procarboxypeptidase to give at least two distinct active enzymes.

In the afternoon session E. Katchalski (Weizmann Institute) surveyed his work on synthetic polyamino-acids and their many applications in biology, including the induction, in 'prolineless' mutants of *E. coli*, of an enzyme, proline imino-peptidase, which digests polyproline; the growing of 'whiskers' of polyamino-acid side-chains on the amino groups of natural proteins; the stabilization of enzymes by binding them to water-insoluble carriers; and the use of polypeptidyl derivatives of aminoacyl compounds of soluble ribonucleic acids to pick out the molecules of *S*-RNA that are specific for particular amino-acids. F. A. Lipmann (Rockefeller Institute) gave a thoughtful and searching discussion of the problems of protein biosynthesis. F. Lynen (Munich) considered the co-ordination of metabolic processes by multi-enzyme complexes, with definite morphological structure, but at a far simpler level than that of the mitochondrion. The protein components possess both catalytic sites and binding sites that hold the components of the complex together. The pyruvate dehydrogenase system (Koike, Reed and Carroll, *J. Biol. Chem.*, **238**, 30; 1963) and the multi-enzyme complex concerned with converting malonyl coenzyme *A* to higher fatty acids—the latter has been investigated intensively in Lynen's laboratory—are outstanding examples of such systems.

On the following day all participants in the symposium journeyed to Jerusalem, where a morning session was held at the Hebrew University, in one of the buildings of the beautiful new campus on Givat Ram. Paul Doty (Harvard) discussed his work, and that of others, on hybrid molecule formation in nucleic acids, and George Klein (Stockholm) considered fundamental problems in the genetic aspects of neoplasia. The afternoon was spent in visiting Jerusalem and its surroundings in Israel, and in the evening the President of Israel gave a delightful and most informal reception for the whole group.

In Rehovoth again, the symposium continued the next day with discussion of nucleic acids. Erwin Chargaff (Columbia University) presented, with clarity and elegance, the problem of nucleotide sequences in nucleic acids, and his own approach to the problem by the use of reagents that selectively attack the purine or the pyrimidine rings—the latter offering far the more difficult chemical problem. David Elson (Weizmann Institute) considered the structure of ribosomes, with particular reference to certain enzymes found in ribosomes. When 70 *S* ribosomes dissociate into 50 and 30 *S* components, at very low Mg^{++} ion concentration, ribonuclease is found exclusively in the 30 *S* component. Deoxyribonuclease is found in neither, but passes into solution, the process being reversible; whereas β-galactosidase is found in both components, and does not leave the ribosomes when they dissociate. He described how transfer (soluble) ribonucleic acid can be obtained from ribosomes exposed to high salt concentration. Alfred Gierer (Tübingen) discussed the mechanism of protein synthesis in reticulocytes, with particular emphasis on the role of polyribosomes, the great importance of which has become manifest only during the past year or so, as a result of work in his and several other laboratories. Severo Ochoa (New York University) discussed the present state of work on the genetic coding problem—a subject so widely known that I omit further comment on it here, in spite of its supreme importance. C. B. Anfinsen (National Institutes of Health, Bethesda) considered the problems involved in predicting three-dimensional structure of proteins from the amino-acid sequence. There is strong experimental evidence from his work on ribonuclease and other proteins that, given the sequence, the peptide chain will fold spontaneously into the correct steric structure, but the problems of predicting this structure are formidable.

That evening, in Tel Aviv, E. B. Chain (Rome, and, eventually, Imperial College of Science and Technology, London) gave a dramatic and very interesting lecture on the newly developed penicillins, which have so significantly enlarged the therapeutic uses of penicillin.

The symposium then turned to problems of development and differentiation. E. Kellenberger (Geneva) reported on the use of facultative lethal mutants for the investigations on the assembly (morphogenesis) of phage particles. These mutants are distributed all over the genetic map, so that they affect numerous genes: 8 genes affect the formation of the phage head. Mutants in some genes produce abnormal assembly of sub-units, as, for example, into long tubes, the 'polyheads'. The sub-units are not self-assembling, but need supplementary information (morphogenetic principles) to be shaped correctly.

The micrographs of 'polysheath', however, suggest that the sub-units of the tailsheath are of the self-assembling type. Leo Sachs (Weizmann Institute) considered problems of cell differentiation and the immune mechanism. Lymphoid cell precursors, in tissue culture, can form essentially pure cultures of either mast cells or antibody-producing cells, provided a suitable layer of other cell types is present in the medium. Lymphoid precursors from lymph nodes of a rat, exposed to mouse cells, differentiate to give cells releasing antibodies, which destroy the mouse cells, that is, this is a heterograft reaction *in vitro*. Both Sachs, and independently Dulbecco, have examined the transformation of normal into tumour cells by the polyoma virus; the virus acts directly on the cells to induce the change. Michael Feldman (Weizmann Institute) considered the role of the thymus in promoting antibody formation in the adult organism, making use of the histocompatibility antigens which are determined by the *Y*-chromosome of male animals. Transfer of such antigens from a male to a female of the same species, in a tissue graft, leads to rejection of the graft by the female, due to an anti-*Y* immune response. Some tumours induced in males cannot grow when transplanted into females, because they evoke a similar response. However, animals previously irradiated with X-rays fail to develop the immune response until after several weeks, and the tumour in the female continues to grow. If the animal has been thymectomized, the immune mechanism does not recover at all after X-radiation; grafting a thymus back into such animals, however, does lead to recovery of the immune response. This recovery is an inductive effect of the thymus; it is not due to production of immunologically competent cells by the thymus itself.

H. H. Weber (Heidelberg) discussed the role of ATP in the active transport of ions, with especial reference to the work of W. Hasselbach in his institute on the vesicles of the sarcoplasmic reticulum, which accumulate calcium ions. There is a very close correlation between the Ca^{++} ions transported and the ATP hydrolysed (2 Ca^{++} per ATP). He concludes that the ATP donates an energy-rich bond to phosphorylate a carrier in the membrane, and that the phosphorylated carrier has an affinity for Ca^{++} several hundred times as great as the unphosphorylated carrier. David Nachmansohn (Columbia University) considered chemical control of movements of ions across conducting membranes, with special reference to nerve and electric organs. Hugo Theorell (Stockholm) set forth, with beautiful clarity, his recent work on complexes of liver alcohol dehydrogenase with coenzymes and inhibitors or substrates.

The last session was devoted to immunochemistry. Michael Heidelberger (Rutgers University) described his recent work on the immunological properties of the capsular material of pneumococci of various types. The structure of the carbohydrates in these capsules is now becoming known in far more detail than ever before—in type *SV*, for example, recent work of Barker in Birmingham, on material supplied by Heidelberger, has identified *N*-acetyl-L-fucosamine and *N*-acetyl-6-deoxytalosamine, among other constituents. These two sugars were never before known in natural products. The chemical identification of antigens by immunochemical techniques is now being refined, and in many cases furnishes a short cut to determination of the structure of the antigen. Michael Sela (Weizmann Institute) described his research work on the development of polyamino-acids and their derivatives as synthetic antigens. One good antigen can be made from polylysine, by first growing alanyl chains on the amino groups of the lysyl side-chains, and then attaching tyrosyl chains to the alanyl chains. If the attachments are made in reverse order—first tyrosine, then alanine—the resulting product is not antigenic. The tyrosyl groups must be on the outside to make a good antigen. The optical specificity of the amino-acids is important—compounds made from combinations of D-amino-acids are generally non-antigenic, even when the corresponding L-compounds are strongly antigenic, as recent work of Gill and Doty has shown (*Nature*, 197, 746; 1963). Dr. Sela's recent work has shown that electric charge is not necessary for antigenicity; they have recently synthesized a water-soluble uncharged polymer that is strongly antigenic (Sela, M., and Fuchs, S., *Biochim. Biophys. Acta*, 74, 797; 1963). When galactose is attached to a synthetic polymer, the galactose grouping becomes a powerful antigenic determinant. Immunological tolerance may be established to synthetic antigens, as shown by experiments on new-born rabbits. The aim of all this research work is to throw light on the nature of the immune mechanisms found in living organisms; the synthetic chemicals are merely a means to this end.

J. C. Kendrew concluded the final session with brief, graceful and humorous comments on some of the major points of the symposium.

One non-scientific interlude deserves mention. Midway in the week we left Rehovoth for a two-day trip along the coast, to Caesarea, Haifa and Acre, then to the Galilee mountains and the Lake of Galilee. We stopped overnight at a kibbutz which, in addition to the usual farming and other community activities, ran a small and very pleasant hotel for visitors. That evening all of us had the opportunity to talk with members of the kibbutz and learn directly about their way of life, its values and its problems. We returned with renewed zest to the scientific conference after this fascinating interlude. In addition to this thoughtfully arranged pause in the symposium, all of us will remember the warm and generous hospitality of our Israeli hosts, during and after the conference, which combined with the high level of the scientific discourse at the meetings to make this a most memorable occasion.

RADIO OBSERVATIONS OF OH IN THE INTERSTELLAR MEDIUM

llege of Science Calcutta

By Dr. S. WEINREB
Lincoln Laboratory, Massachusetts Institute of Technology
Prof. A. H. BARRETT
Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, Mass.
AND
Dr. M. L. MEEKS and J. C. HENRY
Lincoln Laboratory, Massachusetts Institute of Technology, Lexington, Mass.

In this article we wish to report the detection of 18-cm absorption lines of the hydroxyl (OH) radical in the radio absorption spectrum of Cassiopeia *A*, thereby providing positive evidence for the existence of OH in the interstellar medium. The microwave transitions of OH in the ground-state, $^2\pi_{3/2}$, $J = 3/2$, arise from two Λ-type doublet-levels, each of which is split by hyperfine interactions with the hydrogen nucleus, so that four transitions result. The two strongest lines have been previously measured in the laboratory at 1,667·34 ± 0·03 Mc/s ($F = 2 \rightarrow 2$) and 1,665·46 ± 0·10 Mc/s ($F = 1 \rightarrow 1$) with relative intensities of 9 and 5, respectively[1], these results are in agreement with theory The suggestion that these lines might be detected in the radio spectrum of the interstellar medium has been made by Shklovsky[2] and Townes[3] A previous search by Barrett and Lilley[4], in 1956, was unsuccessful, primarily because the laboratory measurements of the frequencies had not been made A recent search for OH emission also yielded negative results[5]

Our observations were conducted on 10 days between October 15 and October 29, 1963, using the 84-ft parabolic antenna of the Millstone Hill Observatory of Lincoln Laboratory, Massachusetts Institute of Technology, and the spectral-line autocorrelation radiometer designed by Weinreb[6] The receiver uses digital techniques to determine the autocorrelation function of the received signal. The resulting autocorrelation function is then coupled directly into a digital computer that performs a Fourier transformation and displays the resulting spectrum on a cathode-ray tube or a precision x–y plotter During one integration time-interval of 2,000 sec, a 100-kc/s portion of the spectrum is determined with a frequency resolution of 7 5 kc/s The ability to see immediately a calibrated visual display of the measured spectrum and average this result with others greatly facilitated the conduct of the experiment and eliminated almost all post-observation data handling The system noise temperature was 420° K, of which 110° K was due to Cassiopeia *A* System tests were performed by observing the hydrogen line

The results obtained during the first evening of our observations showed strong evidence of the 1,667 Mc/s line in Cassiopeia *A*, the signal is visible after 2,000 sec of integration We decided that positive identification of OH absorption lines of Cassiopeia *A* would be secured before proceeding to observations of other regions Our results indicate that two of the three clouds showing strong H absorption[7], namely, those at radial velocities of − 0 8 km/sec and − 48 2 km/sec, also give rise to OH absorption lines that we have detected at both 1,667 Mc/s and 1,665 Mc/s The strong H absorption line at − 38 1 km/sec appears to be composed of two lines at − 37 4 km/sec and − 42 1 km/sec when observed at the OH frequency It is to be expected that a one-to-one correspondence between OH absorption and H absorption will not be observed because of (*a*) greater thermal broadening of H lines, (*b*) larger optical depth of the H lines, (*c*) possible OH/H abundance variations from cloud to cloud A typical record showing the 1,667-Mc/s line in the − 0 8 km/sec cloud is shown in Fig 1 A summary of all of our observations is presented in Table 1

Table 1 SUMMARY OF OH LINE ABSORPTION MEASUREMENTS IN THE CASSIOPEIA *A* RADIO SOURCE

Radial velocity (km/sec)	1,420 405 Mc/s H-line optical depth (ref 7)	1,667 357 Mc/s OH-line optical depth	Observed line width (kc/s)	Number of OH radicals per cm^2	Abundance ratio relative to H
−0 8	1 85	0 016±0 005*	13	~2×10^{14}	~1 5×10^{-7}
−37 2	—	0 010±0 005	13	~1 5×10^{14}	—
−42 1	—	0 012±0 005	20	~3×10^{14}	—
−48 2	4 0	0 016±0 008	25	~5×10^{14}	~1×10^{-7}

* An optical depth of 0 010±0 003 with line width of 16 kc/s was observed for the 1,665 402 Mc/s line

The evidence that we are indeed detecting interstellar OH in these observations may be summarized as follows

(1) Lines at both 1,667 Mc/s and 1,665 Mc/s have been detected with frequencies and intensity ratios that are in good agreement with the expected values

(2) The OH absorption spectra at both frequencies show general agreement with the H absorption spectra

(3) The absorption lines disappear when the antenna is positioned off Cassiopeia *A* by one degree in both azimuth and elevation.

(4) The lines shifted 20 kc/s between October 17 and October 29, this is the shift expected from the orbital velocity of the Earth during this time-interval

A quantity of immediate astrophysical interest which follows from our observations is the abundance ratio of OH to H This can be obtained in the following way the spectral change in antenna temperature ΔT_{OH} owing to the OH absorption is given by

$$\Delta T_{\text{OH}} = \tau_{\text{OH}} T_{\text{AC}}$$

where τ_{OH} is the OH optical depth in the direction of Cassiopeia *A* and T_{AC} is the antenna temperature attributable only to Cassiopeia *A* The maximum optical depth is given by

$$\tau_{\text{OH}} = \frac{hc^2 A N_{\text{OH}}}{8\pi k T_s \nu_0 \Delta\nu} \frac{g_i}{\Sigma g_i}$$

where A is the spontaneous transition probability, T_s is the excitation temperature analogous to the H spin temperature, ν_0 is the line frequency, $\Delta\nu$ is the line width, g_i is the statistical weight of level i, and N_{OH} is the total number of OH radicals per unit cross-section The statistical weight g_1 of the upper level of the 1,667-Mc/s transition is 5, and for the 1,665-Mc/s transition it is 3, the sum of the statistical weights for all levels is 16 The spontaneous transition probability A must be evaluated by using the matrix element derived from a quantum-mechanical treatment of Λ-type doubling[8], and has the value 2 86 × 10^{-11} sec^{-1} for the 1,667-Mc/s transition The OH dipole moment used in these calculations[9] is (1 60 ± 0 12) × 10^{-18} E S U

The excitation temperature T_s is the subject of considerable uncertainty because it cannot be assumed that it will be

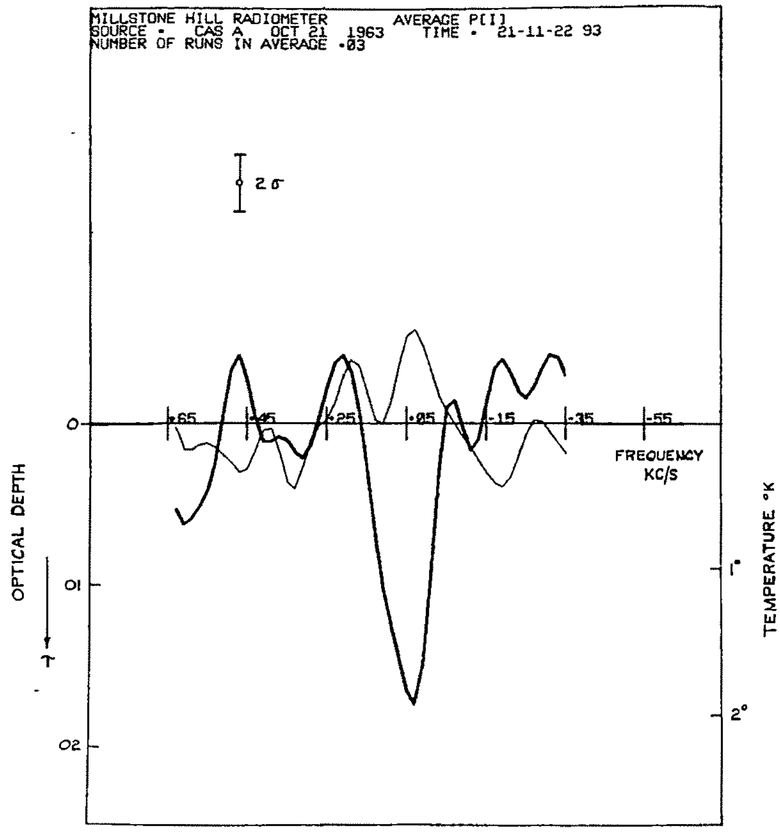

Fig 1 Observed 1,667 Mc/s OH absorption spectrum in Cassiopeia *A* The heavy line shows 8,000 sec of data taken with the antenna beam directed at Cassiopeia *A*, and the light line shows 6,000 sec of data taken with the beam displaced slightly from Cassiopeia *A* The frequency scale is specified in kc/s with respect to the local standard of rest assuming the line rest frequency to be 1,667,357 kc/s

the same as that for H The excitation temperature is defined by the relation

$$\frac{n_i}{n_0} = \frac{g_i}{g_0} e^{(-h\nu)/(kT_s)}$$

where n_i and n_0 are the densities of radicals in the upper and lower states of the transition, respectively For H it has been shown that T_s equals the kinetic temperature in a typical galactic gas cloud[10] because radiative transitions are relatively rare as compared with collisional transitions For OH, however, the spontaneous transition probability is 10^4 times larger than for H, so radiative transitions play a more dominant part in establishing the equilibrium population distribution A detailed evaluation of the processes that will be important in determining the OH excitation temperature has not been made, but a preliminary investigation shows that slow-moving positive ions may be very effective in inducing transitions between the two states, in spite of their low abundance in a H cloud[11] This situation arises because the OH transition is of an electric dipole type, and therefore can be induced by the Coulomb field of electrons and ions which leads to large interaction radii A similar result has been obtained by Purcell when considering the population of the fine-structure states of the $n = 2$ level of H in the solar atmosphere[12] An upper limit on T_s can be set by our observations off Cassiopeia *A* from which one would expect to detect OH emission From the preliminary observations we conclude that any OH emission adjacent to Cassiopeia *A* is less than 1° K, this result implies a T_s less than 50° K for an optical depth of 0 02 For purposes of computing the total number of OH radicals from the foregoing equations we have assumed a T_s of 10° K More extensive observations for OH emission will enable a better estimate of this quantity to be made

The values of the number of OH radicals per cm² in the direction of Cassiopeia *A* are shown in Table 1 The OH/H abundance ratio can be calculated from the results of the H absorption on Cassiopeia *A*[7], and gives typical ratios of 1×10^{-7} (see Table 1) This ratio can be compared with estimates of the CH/H abundance ratio 10^{-6} by Stromgren[13] and 2×10^{-8} by Bates and Spitzer[14].

Our observations have enabled a more accurate determination of the frequencies of the two strongest Λ-type doublet lines of OH The laboratory and astronomical values are shown in Table 2 It is possible that these values will be of interest to the molecular spectroscopist for a more accurate evaluation of the hyperfine coupling constants.

Table 2 REST FREQUENCY OF OBSERVED LINES

Transition	Laboratory measurement	Astronomical measurement
$F=2\rightarrow2$	1,667,340±30 kc/s	1,667,357±7 kc/s
$F=1\rightarrow1$	1,665,460±100 kc/s	1,665,402±7 kc/s

We thank many people for their co-operation in this experiment We also thank R E Gay, P J Conrad, C Blake, R H Erickson, J F MacLeod, and the entire personnel of the Millstone Hill Observatory for their assistance

The work of one of us (A H B) was supported in part by the U S Army, the Air Force Office of Scientific Research, and the Office of Naval Research, and in part by the National Aeronautics and Space Administration (Grant *NsG*–419) Lincoln Laboratory is a centre for research and development operated by Massachusetts Institute of Technology with the support of the U S Air Force

OBITUARIES

Dr. A. A. Griffith, C B E., F.R.S.

ALTHOUGH the name of Dr A A Griffith, who died on October 11, was not well known by the general public, he was a creative and original thinker who had considerable influence on the development of jet propulsion systems A champion of the high-efficiency axial compressor while Whittle was experimenting with the more robust centrifugal engines, Dr Griffith continued to be ahead of his time in urging, in turn, the by-pass system, small engines for jet lift, the use of hydrogen as a fuel, and had still other novel projects under consideration at the time of his death

Dr Griffith was born on June 13, 1893, and attended secondary school at Douglas in the Isle of Man A Tate technical science scholarship took him to the University of Liverpool in 1911, where he obtained successively a B Eng (first-class honours in mechanical engineering), M Eng (1917) and D Eng (1921)

His first interest was in mechanics, and his joint paper with G I Taylor on the use of soap films in solving torsion problems gained the Hawksley Gold Medal from the Institution of Mechanical Engineers in 1917 His famous paper on "Theory of Rupture", in which he used surface energy considerations to determine the stress conditions under which a crack will propagate and lead to failure of a material, was published in 1920, and the concept of the 'Griffith Crack' was discussed at the first International Congress on Applied Mechanics at Delft in 1924

He had no regular apprenticeship, but received general workshop training between July 1915 and November 1916 at the Royal Aircraft Factory Following this training, he was successively draughtsman, technical assistant and senior technical assistant in the Physics and Instrument Department at the Royal Aircraft Establishment During April 1920–April 1928 he was a senior scientific officer in the Physics and Instrument Department, Royal Aircraft Establishment, and then principal scientific officer in charge of the Air Ministry Laboratory, South Kensington, until April 1931, dealing chiefly with engine and instrument work

During this period he became a firm advocate of the gas turbine for aircraft propulsion, and in 1926 wrote a Royal Aircraft Establishment report entitled "An Aerodynamic Theory of Turbine Design", in which he formulated a number of new ideas Under his supervision, work on a turbo-compressor test rig was started at the Establishment in 1927

In 1931, Dr Griffith was made principal scientific officer in charge of engine research, Engine Department, Royal Aircraft Establishment, in November 1938, the acting head of the Department, and later head of the Department at the Royal Aircraft Establishment until May 1939

During 1921–31, he was an official member of the Elasticity and Fatigue Sub-Committee of the Aeronautical Research Council and then official member of the Engine Sub-Committee, Aeronautical Research Council, until 1939 His connexion with the Council continued until his retirement in 1960 Indeed, in his later years he used the Committee as his main vehicle of communication with the technical world, he published little elsewhere, largely because of the relevance of his work to defence projects

He was a founder member of the Gas Turbine Collaboration Committee

On June 1. 1939, Dr Griffith took up the position of research engineer of Rolls-Royce, Ltd , at Derby, working on the initiation and prosecution of aero engine research, responsible to Mr E W Hives, general manager (later Lord Hives chairman) He was given a pleasant room at Duffield Bank House, a quiet haven on the banks of the Derwent, five miles from Derby

Griffith's first work, completed in 1941, was an axial flow jet engine including twenty contra-rotating compressor stages, each driven independently by turbine blades at the tips of the compressor blades, ducted fan propulsion, centrifugal fuel supply and other items that were far in advance of contemporary practice The high-pressure part of the system was, in fact, built and tested Throughout his work on jet propulsion, Dr Griffith believed in the superior efficiency of the axial type compressor, and the contra-flow engine was followed by a series of design investigations of axial types, parallel with work on many component rig test investigations of combustion, blade form and rotor design

A technical memorandum prepared by Dr Griffith in 1945, together with a preliminary design scheme created under his supervision, were the basis of the Rolls-Royce Avon engine, this was followed in 1946 by his proposals for a by-pass engine Preliminary design schemes for the latter type were completed early in 1947 and led to the Rolls-Royce Conway engine

Early in 1941, Dr Griffith realized that the thrust potential of a turbine engine, combined with its low weight, provided a basis for the design of an aircraft which could take off and land vertically by virtue of engine thrust alone and thus only need sufficient wing area for its cruise condition He made a detailed investigation of engine weight relative to size and showed that the 'Square-Cube' law, by which an engine's weight decreases as the cube of its linear dimensions, whereas the thrust only decreases as the square, would hold good down to quite small unit sizes This convinced him of the advisability of using a number of small engines in order to obtain the optimum lift/weight ratio for vertical take-off applications His first design studies of vertical take-off aircraft incorporated a multiplicity of small engines with means for deflecting their thrust downwards for taking-off and landing, control of the aircraft in the jet-borne phase being by variation of the thrust of engines situated fore and aft for pitch and separated laterally for roll The possibility, with this scheme, of difficulty due to insufficiently rapid thrust-response rate led Dr Griffith to the idea of using compressed-air jets fed from engine compressor air bleed

He conceived the scheme for testing this system, now well known as the 'Flying Bedstead', and supervised the preliminary design scheme, which incorporated two Rolls-Royce Nene turbine engines arranged back to back with their thrust deflected downwards in a central position Control air was tapped from the engine compressors and fed to control nozzles positioned fore and aft and on outriggers laterally On August 3 1954, this jet-lift test rig achieved its first free flight for 8½ min Many subsequent flights clearly demonstrated the success of Dr Griffith's vertical take-off proposals Parallel with these tests and until his retirement in 1960, Dr Griffith initiated many aircraft design studies using specially designed lightweight lift engines and separate engines for forward thrust Late in 1953 he commenced a detailed investigation of a supersonic jet-lift transport designed for a Mach No of 2 6 at 60,000-ft altitude

Dr Griffith's work was recognized by fellowship of the Royal Society in 1941, a C B E in 1948, the award of the Silver Medal of the Royal Aeronautical Society in 1955 and, in 1962, the Bleriot Medal

Although Dr Griffith was very little known to most people within Rolls-Royce, due partly to the secluded location of his office, I was privileged to be his personal assistant and designer for twenty-one years, sharing his office for sixteen years at Duffield Bank House and later having an adjoining design office at Littleover Old Hall for the five years prior to his retirement

Alan Arnold Griffith was truly a man of vision, quiet and retiring, resisting publicity yet fascinating to know intimately by daily contact His brain provided new lines of thought for development in a continuous flow and our discussions were often enlivened by his ready wit and good humour DONALD EYRE

Prof E P. Sharpey-Schafer

EDWARD PETER SHARPEY-SCHAFER, professor of medicine in the University of London at St Thomas's Hospital Medical School, died on October 23 at the age of fifty-five

His father was killed in the First World War and consequently he was brought up in the house of his famous grandfather, Sir Edward Sharpey-Schafer He went to school at Winchester and entered King's College, Cambridge, as an exhibitioner and Kitchener Scholar His clinical studies were completed at University College Hospital where he obtained the Fellowes Gold and Silver Medals After qualifying, he held the post of house physician to Sir Thomas Lewis, a position which he spoke of with great pride in later years After serving as resident medical officer at the National Heart Hospital, he joined Sir Francis Fraser as first assistant in the Department of Medicine in the early days of the Postgraduate Medical School He was appointed professor of medicine at St Thomas's Hospital Medical School in 1948

It is impossible to assess the enormity of the loss which St Thomas's Hospital has suffered in the death of Prof Sharpey-Schafer He is the third member of their consultant staff to die in recent months, and though they were all men of high intellect and profound wisdom, he was undoubtedly the greatest of the three Only those who were close to him had the opportunity to know him He was essentially a shy man, which led people to think his manner brusque and off-hand, but his great human qualities showed themselves when he considered that someone was being treated unjustly The same consideration for others was manifest in his investigations on patients if ever it became apparent that one was suffering discomfort he immediately abandoned the procedure

Prof Sharpey-Schafer was an outstanding research worker who is known throughout the world for his work on the circulation However, he entered the field of original work in endocrinology and made important contributions in investigations of the thyroid, acromegaly and ovarian function Although he forsook this sphere during the War, he still taught the younger endocrinologist some fundamental facts years later

With Prof J McMichael he introduced cardiac catheterization as a method of examination of the cardiovascular system From then onwards he continued to be fascinated by the control mechanisms in this system in health and disease Every week he continued to make simple but fundamental observations on his patients, and a steady stream of original work flowed from his pen He investigated hæmorrhage and heart-failure and remarked on the aspects of similarity in these two conditions One of his particular achievements was the demonstration of vasodilatation in fainting subjects and the part played by complete immobility when soldiers fainted on parade. He demonstrated the vascular reflex abnormalities in patients with tabes dorsalis, diabetes and barbiturate intoxication. This led to the simple treatment of the latter group of patients by blood volume expansion when they lapsed into a hypotensive state. Of recent years his dominant interest has been in the control of venous tone, and this led him on to the vascular changes during exercise. For months on end he would talk to all and sundry about this problem until he found at least a partial answer in the realm of chemistry. This was rather unfamiliar territory to him and he soon enlisted the assistance of one of his staff in a series of conclusive investigations.

When Prof. Sharpey-Schafer first arrived at St. Thomas's Hospital he and his staff were thought of as experimentalists. He had an uphill task in earning the esteem and respect of the clinically orientated members of the nursing and medical staff. As the years passed he became more and more valued for his judgement both of individuals and of problems. Of the many people who sought his help and advice, not one was let down. The references he wrote for the junior members of the hospital staff sparkled with wit and impressed themselves on the reader by their originality. No idle clichés were ever found in these or any other of his writings.

Perhaps one of the most striking aspects of the personality of Prof. Sharpey-Schafer was his attitude to orthodoxy. He declared that he had an abhorrence for the whole of the pharmacopœia, and on one occasion to stress the point he crossed off all the drugs on his patients' treatment cards. He delighted in poking fun at the Establishment and in *Who's Who* stated that his recreation was "childish pursuits". In fact, he was a keen and accomplished naturalist and photographer, and when he produced a new batch of his colour photographs of birds or insects he was armed also with all the fascinating details of their life-habits, such as the speed of their wing beats, time and place of emergence, etc.

Those who knew "Sharpey" well appreciated the warmth of his character, his unfailing loyalty and the high standards which he demanded of everyone engaged in research. He was a man who always kept to his word and who could be relied on to help anyone who was in need. He will be an inspiration to all those who worked with him, but few will reach the standards which he achieved.

Prof. Sharpey-Schafer leaves a son and daughter by his first marriage. He married Dr. Sheila Howarth and they had two daughters. IVOR H. MILLS

NEWS and VIEWS

School of Science: Massachusetts Institute of Technology

DR. JEROME B. WIESNER has been appointed Dean of the School of Science in the Massachusetts Institute of Technology. Dr. Wiesner, now special assistant for science and technology and director of the U.S. Office of Science and Technology, will succeed Dr. George R. Harrison, who will retire at the end of this year.

Dr. G. R. Harrison

DR. HARRISON graduated from Stanford University and received his Ph.D. degree there in 1922 while an instructor in physics. After two years as a National Research Fellow at Harvard University he returned to the Stanford faculty and remained there until his appointment at the Massachusetts Institute of Technology in 1930. He was director of the Research Laboratory of Experimental Physics for twelve years before becoming dean of the School of Science in 1942. In spectroscopy, his field of specialization, Dr. Harrison invented several instruments of great value and compiled the *M.I.T. Wavelength Tables*, an encyclopædic work used by spectroscopists throughout the world. He was editor of the *Journal of the Optical Society of America*, co-author of *Practical Spectroscopy* and author of *Atoms In Action*, *What Man May Be*, and other books. During the Second World War, Dr. Harrison was chairman of the Instruments Section, and later chief of the Optics Division of the National Defense Research Committee, Office of Scientific Research and Development, and, for a time, chief of the Research Division at General MacArthur's headquarters in the south-west Pacific. He received the War Department Medal of Freedom and Presidential Medal for Merit. He was awarded the Rumford Medal of the American Academy of Arts and Sciences, the Frederic Ives Medal of the Optical Society of America, the Elliott Cresson Medal of the Franklin Institute and the Medal of the Society of Applied Spectroscopy.

Dr. J. B. Wiesner

DR. WIESNER received bachelor of science, master of science and doctor of philosophy degrees from the University of Michigan. In 1940 he was appointed chief engineer of the Acoustical and Record Laboratory of the Library of Congress and in 1942 went to the Radiation Laboratory at Massachusetts Institute of Technology, where he was a member of the Microwave Components Division and then group leader of 'Project Cadillac', assigned to devise an airborne radar system. After the War, Dr. Wiesner spent a year at Los Alamos, returning to the Institute as assistant professor of electrical engineering. He was made an associate professor in 1947, professor in 1950 and Institute professor in 1962. In 1947 he became assistant director of the Research Laboratory of Electronics, in 1949, associate director, and in 1952, director. He was appointed acting head of the Department of Electrical Engineering in 1959. Dr. Wiesner's scientific contributions, particularly in the field of microwave theory, have been notable. He was chairman of the Institute's steering committee for a Center for Communication Sciences established in 1958. Dr. Wiesner was staff director of the American delegation to the Geneva Conference for the Prevention of a Surprise Attack in 1958, and for a number of years he has devoted much effort to the search for methods of arms control. Already a member of the President's Science Advisory Committee, he went on leave from the Institute in 1960 to become special assistant for science and technology to President Kennedy. He was also made director of the Office of Science and Technology when that agency was established in 1962. He has received the President's Certificate of Merit and is a member of the National Academy of Sciences.

"Isotopes": the Fiftieth Anniversary

ON December 4 the Chemical Society (president, Prof. J. Monteath Robertson) will meet in the Department of Chemistry, University of Glasgow, to commemorate Frederick Soddy's communication in *Nature* of exactly fifty years ago (92, 399, December 4, 1913). Soddy was then working in the Physical Chemistry Laboratory of the University of Glasgow. This was a time of intense research and rapid advance in all fields of radioactivity. Although priority issues are inevitably debatable, it remains evident that the University of Glasgow made an important contribution by creating a lectureship in "Physical Chemistry including Radio-activity" (1904) and appointing the youthful Soddy His work there on isotopes resulted in the communication in *Nature*, where, from the various explanations of "chemically inseparable" substances, he came down firmly for "isotopes"—for which he there first adopted the name—and also provided a valid interpretation of atomic number in terms of nuclear charges This work on isotopes is referred to in his Nobel prize citation (1921) Soddy's Glasgow colleagues, Lord Fleck and John A Cranston, will speak on these researches, H J Emeleus will review the present field of radiochemistry, and Dr Andrew Kent will present a historic note

Basic Research at the Royal Armament Research and Development Establishment: Dr J W Maccoll

ON September 30, Dr. J W Maccoll retired from the post of principal superintendent of the Basic Research Division of the Royal Armament Research and Development Establishment, Fort Halstead Dr Maccoll, who was born in Aberdeenshire, graduated B Sc at the University of Glasgow in 1924, where he studied mechanical engineering and pure science, and afterwards pursued aerodynamic researches under Thom at Glasgow, Bairstow at the Imperial College of Science and Technology, where he took his Ph D in 1927, Prandtl at Gottingen, and von Kármán at Aachen He joined the Ordnance Board as ballistic research officer in 1929, to apply the principles of aerodynamics to ballistics, and it was in the 1930's that his fruitful collaboration with Sir Geoffrey Taylor led to their classic paper on 'Taylor–Maccoll' flow, and other papers Following the report of the Guy Committee in 1942, and the creation of the Armament Research Department with Prof (later Sir) John Lennard-Jones as its first chief superintendent, Dr Maccoll was first appointed deputy superintendent and, later, superintendent of the newly formed branch for theoretical research Since 1945 he has been in charge of basic research at Fort Halstead and has built up, over the years, a substantial group, with extensive experimental facilities for work on hypersonic flow, hypervelocity projection and flow in the upper atmosphere, and with up-to-date facilities for high-speed computation (see *Nature*, 185, 346, 1960) Dr Maccoll, who has always been a well-known figure at scientific meetings, will be remembered, particularly in the Scientific Civil Service, for the importance he has always attached to sound fundamental research, for his scientific foresight and his shrewd judgment Although officially retired, he has not severed his connexion with the Royal Armament Research and Development Establishment, but is maintaining his interest in the work of the Establishment by acting as a part-time consultant

Genetics in the University of Leicester: Prof R. H. Pritchard

DR R H PRITCHARD, who has been appointed to the newly established chair of genetics in the University of Leicester, has distinguished himself especially by his studies on the properties of the genetic material of micro-organisms Using a selective technique which permitted a high degree of resolution, he showed that the processes of recombination between sites very close to each other on the chromosome of *Aspergillus nidulans* obeyed rules different from those governing recombinations between more distant sites His present work, with *Escherichia coli*, is contributing greatly to the elucidation of the factors underlying thymine-less death and induction in lysogenic bacteria Dr Pritchard, who was born in 1930, gained the Carter Gold Medal and first-class honours in botany from King's College, London, prior to joining the Department of Genetics in the University of Glasgow in 1951 After completing his Ph D work, he spent a year as Rask-Ørsted Fellow in the University of Copenhagen He returned to Glasgow in 1955 and remained there as, successively, Nuffield research assistant and lecturer until his appointment to the staff of the Medical Research Council's Microbial Genetics Research Unit at the Hammersmith Hospital in 1959 The selection of Dr Pritchard to head a new Department in the University augurs well for the continued development of biological studies at Leicester

New Department of Microbiology in the Queen's University of Belfast

LORD HARDING OF PETHERTON, chairman of the National Fund for Research into Poliomyelitis and other Crippling Diseases, laid a plaque to mark the foundation of a new building for the Department of Microbiology, Queen's University of Belfast, on November 12 The National Polio Fund made a grant of £70,000 towards the cost, the Northern Ireland Hospitals Authority is contributing £50,000 and the balance of cost of approximately £350,000 is to be met by the Government of Northern Ireland Sir Hugh Casson is the architect of the new building, which is being erected near the Institutes of Pathology and of Clinical Science on the hospitals site at Grosvenor Road It is linked to these Institutes and to the Royal Victoria Hospital It provides in a podium extensive animal houses and in five floors teaching and research laboratories and a virus reference laboratory for the Hospitals Authority The building is expected to be completed by October 1964

Science and Adult Education

A REPORT entitled *Science and Adult Education*, issued by the Association of Scientific Workers, recommends that in view of the importance of science and technology to the nation, the number of science classes in adult education should be increased to 20 per cent of the total within the present quinquennium, and especially in the longer courses (Pp 11 London Association of Scientific Workers, 1963 2*s*) This extension should be directed particularly at students with little or no previous education in science, and additional funds for this extension should be made available by the Ministry of Education. Some additional full-time appointments of science tutors with responsibility for both teaching and expanding the provision of science classes should be made by extra-mural departments and by the Workers' Educational Association An immediate and substantial increase in the fees of part-time tutors is proposed as well as funds for extending special experimental schemes Special attention should be directed to including science courses in summer schools and week-end schools to create an atmosphere in which science is regarded as a normal feature of adult education, to ways of integrating science into courses in social studies and the arts, and to ways of adapting science courses for the needs of special groups More books suited for adult teaching are required and the publication of such books by successful tutors should be encouraged Branches of the Workers' Educational Association should be encouraged to discuss ways of recruiting students for science classes and of conducting publicity for such classes

Shortage of Science Teachers

THE report of a recent survey carried out by the National Union of Teachers, by means of a questionnaire, to which 22,000 schools responded, throws further light on the shortage of specialist teachers in England and Wales (*The State of Our Schools a Report of the Findings of the National Survey of Schools, 1962* Part 3 *An Analysis of the Findings Relating to Grammar Schools, Comprehensive Schools and Special Schools* Pp 19 London National Union of Teachers, 1963 2*s* 6*d*) In grammar schools, among all subjects, the greatest shortages are in mathematics, in which 28 additional teachers are required per 100 schools, and in science, for which the deficiency is 24 After these, the next most serious shortages are in English and foreign languages In comprehensive schools, which as a whole are of more recent construction, the shortages are still greater, the figures being 68 for mathematics, and 59 for science—along with 32 for English, 27 for geography, 23 for foreign languages and 22 for history Once again this survey brings out the meagre provision in both types of school for the teaching of engineering, mechanical and geometrical drawing, and rural science Most of the larger grammar schools and three-quarters of the smaller ones obtain some assistance with laboratory work Among other deficiencies of various kinds which the survey reveals, one striking fact is the acute shortage in comprehensive schools of teachers specially trained to teach backward children These deficiencies are not merely matters of school administration, for it is clear that, to a certain extent, among young people, a scientific attitude can be fostered by appropriate upbringing and training, while in varying degree there is scope for scientific ability at all levels and in all sectors of society The deficiencies, therefore, are symptomatic of weaknesses in Britain's national culture

Research in South African National Parks

THE varied subjects of the papers published in *Koedoe*, the journal for scientific research in the national parks of the Republic of South Africa (No 6, 1963), show the scale of the work being carried out under the auspices of the National Parks Board of Trustees A number of systematic and distributional investigations of both vertebrates and invertebrates is included as well as several very interesting contributions on the use of different immobilizing drugs in the capture of large mammals The use of such drugs is rapidly becoming widespread not only for bringing wild animals into captivity, but also in the scientific study of their biology, for it enables close examination to be made and marking by ear-tags or other means to be carried out An interesting collection of photographs illustrates the technique by which a syringe containing the drug is incorporated in a dart fired from a special gun or crossbow A drug for use with all species of mammals has not yet been made, but excellent results are being obtained by combining the immobilizing and tranquillizing drugs in varying doses according to species A paper by Pienaar and Van Niekerk describes the use of a tranquillizer on a number of oribi captured by driving them into nets in order to introduce them into the Kruger National Park, where the species became extinct in 1943

The National Art Gallery and Dominion Museum, New Zealand

As with so many museums and art galleries, both in Britain and abroad, the real bottleneck at the National Art Gallery and Dominion Museum, New Zealand, is not finance but space for exhibits, for storage and for working While plans under consideration for the transfer of the Art Gallery to a new building may provide an ultimate solution, the Museum must seek some immediate relief within a much shorter time than it will take to build a new Art Gallery The annual report for the year ended March 31, 1963, states that efforts have been made to persuade the Police Department to vacate the building on the Board's property which is still used as a clothing store (Pp 26 Wellington, New Zealand Government Printer, 1963 1*s* 6*d*) Public relations are given constant attention, and in recognition of a considerable degree of municipal support the Museum tries to make its contribution as a civic community

The Yale Peabody Museum of Natural History, New Haven, Connecticut

ANNUAL Report No 4–1963 of the Yale Peabody Museum of Natural History, New Haven, Connecticut, is the record of a progressive institution with a relatively large staff engaged on research and teaching as well as normal museum activities (Pp 60+13 photographs New Haven, Conn Yale Peabody Museum of Natural History, 1963) Dr S Dillon Ripley, the director, stresses the fact that research leads to the development and refinement of the exhibits Sarawak Museum in Borneo presented four specimens of *Lanthanotus borneensis*, one of the rarest and most primitive of living reptiles It is an earless animal, of which only eighteen specimens are known in the world, and figures significantly in the hypothesis that snakes were derived from some monitor-like lizard in that it possesses many of the structures to be expected in an ancestor It was discovered in 1878, and so little is known of its habits that the first observation of its feeding occurred in New Haven in 1963

The Smithsonian Institution, Washington

THE annual report of the Smithsonian Institution for 1962 is, as usual, a large volume of several hundred pages recording the strengthening of the academic staff, and progress in the renovation of the exhibits (Pp x+610+106 plates Washington, D C Government Printing Office, 1963 4 75 dollars) Attendances reached the high figure of 8,923,131—an indication of the popularity of the Smithsonian Institution The great study collections are utilized by hundreds of research workers from other Government bureaux and from universities all over the United States The total number of catalogued objects now in the Smithsonian is nearly 56 million When the east and west wings of the Natural History Building are completed and opened for use and when the great new Museum of History and Technology is open, the effectiveness of the whole pattern of public display and of the use of study collections will be greatly appreciated.

Register of Research in the Human Sciences (1960–63)

THE second edition of the *Register of Research in the Human Sciences* (*1960–63*), compiled by the Warren Spring Laboratory of the Department of Scientific and Industrial Research, has recently been published (Pp. vi+226 London H M S O, 1963 20*s* net) The new edition presents a much more comprehensive account of research in this field and in fact contains twice as many entries as its predecessor Included within this title of "Human Sciences" are abnormal psychology, demography, developmental psychology, experimental psychology, industrial psychology, industrial sociology, physiological psychology, public administration, rural sociology, social anthropology, social disorganization, social economics, social geography, social history, social medicine social psychology, social stratification, and urban sociology The entries are arranged in broad subject headings and underneath are grouped in alphabetical order the names of the research institutions Throughout, the research projects are numbered Then follows a brief description of the projects, the person (or committee) responsible for the research, research workers, approximate starting date, approximate date of completion, interim results, final results, parties concerned with enquiries and other information Two indexes are provided, the first deals with institutions giving address, telephone number, name of person in charge, etc , the second is a subject index covering all fields from "absenteeism" through "crime", "housing", "management", "rural communities", "smoking", "under-developed countries", to "youth groups", etc

Family Planning

FACED with a world population which could possibly be double that of the present 3,000,000,000 within forty years, the Family Planning Association has decided to launch a massive international campaign The fact that the Association is embarking on this campaign does not mean that it wants to urge developing nations to adopt birth control or population limitation as such Countries must decide their own population policies, but an increasing number are adopting family planning some because they have a serious abortion problem, others because their economic development is greatly hampered—indeed sometimes prevented—by population increases which rapidly absorb the results of all attempts to raise the standard of living Lord McCorquodale of Newton has agreed to become chairman of the Campaign Committee, which is composed of a number of prominent social, industrial and scientific workers Details of its work are set out in the thirty-second annual report, which also describes the remarkable increase in clinics and services which the Association is providing throughout Britain (Pp 22 London The Family Planning Association, 1963) At the end of April, 1963, 163 clinics were prescribing oral contraceptives, 51 clinics are able to offer facilities for taking cervical smears

Prehistoric Cultures of North-east Angola

Prehistoric Cultures of North-east Angola and their Significance in Tropical Africa, by Prof J Desmond Clark, is the title of a monograph published through the Dundo Museum by the Companhia de Diamantes de Angola (Diamang) (*Publicacoes Culturais*, No 62 Part 1 Pp 222, Part 2 Pp 225–385 (80 plates) Lisboa Companhia de Diamantes de Angola, 1963). It is a serious study of the prehistory of North-east Angola by one of our foremost prehistorians For many years, Prof Clark was the curator of the Museum at Livingstone and is now professor at Berkeley University in California The volumes start with an interesting table giving the radiocarbon dates and pollen analyses for the various cultures and the climatic stages during which they occur Thus, the Sangoan of the early Gamblian is dated as far back as 38,000 years, while the Makalian (Tshitolian culture) can be fixed at about 6,830 years ago In the preface, Prof Clark pays tribute to the late J Janmart, formerly head of the prospecting department, whose intense interest in the cultures of the area largely started these cultural studies He also mentions, among other colleagues, Mrs Clark, who has made the excellent line drawings of the implements which illustrate the work A short outline of the relevant geology is given, and this is followed by a note on the raw materials used by prehistoric man The various climates then come under review Chapter 3 describes the stratigraphical and cultural succession in Lunda. the terminology in general use in the Congo being used There are numerous maps and sections given, which illustrate the sequence Chapter 4 continues the story given in Chapter 3, but is concerned with more recent times There follow chapters describing in greater detail the industries produced by the various cultures present These are, of course, of very great interest to the specialist Angola has from time to time been a refuge area when climate changes elsewhere have become such that human existence became difficult As a result, the typological studies of the various industries compared with those from other localities are a matter of great interest Volume 2 is devoted to illustrations of tools and photographs of a number of sites having a separate volume for these illustrations makes close study of the different cultures very much easier The two volumes will be of great value to anyone wishing to know about the prehistory of this interesting region of Africa Prof and Mrs Clark are to be congratulated on the result, and the Companhia de Diamantes de Angola for financing these publications

Barnard's Star

BARNARD'S STAR is the second nearest known stellar system, with apparent visual magnitude 9 5, a parallax of 0″ 55 and a proper motion of 10″ 3 per annum It has been investigated at the Sproul Observatory of Swarthmore College by P van de Kamp (*Astronomical J*, 68, 515; 1963) on photographs taken over a period of forty-five years, 2,413 plates with 8,260 exposures obtained on 609 nights by many observers Barnard's Star has the largest known secular perspective acceleration in proper motion This was determined (−0″ 00014 in R A, +0″ 00118 in declination) The residuals of the observations from the predicted positions allowing for proper motion, secular acceleration and parallax were investigated The residuals showed a periodicity of about 24 years, and indicate the presence of a companion A semi-axis major of 0″ 0245 and an eccentricity of 0 6 for the main star fit the observations If the mass of Barnard's Star is 0 15 solar mass, the companion has an orbit with semi-axis major of 2″ 4, or 4 4 astronomical units, and from the displacements of the main star it can be shown that the mass of the companion is 0 0015 solar masses, or 1 6 times the mass of Jupiter Its apparent visual magnitude would be perhaps 30, far below the reach of existing telescopes

Modern Instrumentation in Science and Industry

ON January 17, 1964, the London Sections of the Institute of Biology, the Institute of Physics and Physical Society, and the Royal Institute of Chemistry will hold a one-day symposium on "Modern Instrumentation in Science and Industry" at the Institution of Electrical Engineers, Savoy Place This is the latest of a series of successful joint symposia held by the London members of three Institutes, and will deal with some general (morning session) and some specific (afternoon session) aspects of the use of instruments and automated plant in biology, chemistry and physics The chairman of the symposium will be Sir John Cockcroft Of special common interest will be a lecture by G Malcolm Dyson, research director of the Chemical Abstracts Service, on "The Correlation of Chemical, Physical and Biological Properties of Substances by Mechanized Programmes" Other speakers are W Grey Walter (Burden Neurological Institute, Bristol) on "Some Aspects of Instrumentation in Experimental Physiology", R S Medlock (George Kent, Ltd, Luton) on "Automatic Control in Chemical Industries", P H Hammond (Autonomics Division, National Physical Laboratory) on "Self-Optimizing Control Systems", J M Hirst (Rothamsted Experimental Station) on "Measurements of Foliage Infection by Fungal Pathogens", V S Griffiths (Battersea College of Technology) on "Automatic Control in the Chemical Laboratory", and S Arnott (Medical Research Council Unit, King's College, London) on "Recent Developments in Molecular Biology" The lectures will be followed by discussion There is a registration fee of £1 for members of the participating societies and £3 for non-members, which will include refreshments and pre-prints Tickets can be obtained from the Finance Officer, Royal Institute of Chemistry, 30 Russell Square, London, W C 1

The American Geographical Society. Elections

THE following have been elected Honorary Fellows of the American Geographical Society· Dr George Wust director of the Kiel Oceanographic Institute, Kiel, Germany, now visiting professor of oceanography at Lamont Geological Observatory, Columbia University, Dr John Quincy Stewart, associate professor emeritus of astrophysical sciences at Princeton University, and Dr Gilbert F White, former president of Haverford College, now professor of geography at the University of Chicago

Gairdner Foundation Awards

THIS year's Gairdner Foundation awards have recently been announced The Foundation was established in 1957 by J A Gairdner, the Toronto industrialist Annual

Awards of 5,000 dollars and Awards of Merit of 25,000 dollars are bestowed on those who "have made contributions to the conquest of disease and the relief of human suffering" The following are the most recently announced

Award of Merit to Dr Murray L Barr, head of the Department of Anatomy, University of Western Ontario, for his discovery of the fundamental difference between male and female cells, thus contributing to greater knowledge of factors governing heredity

Annual Awards to Dr Jacques Genest, director of clinical research, Hotel Dieu Hospital, Montreal, for his work on high blood-pressure, Prof C Walton Lillehei, professor of surgery, University of Minnesota, Minneapolis, for development of several pioneering techniques in open heart surgery, Dr Irvine H Page, director of research, Cleveland Clinic Foundation, Cleveland, Ohio, for discoveries linking the kidney to high blood-pressure, Prof E G L Bywaters, professor of rheumatology, University of London, for his work on the clinical features of rheumatoid arthritis which have delineated the special features of the course of the disease, Dr Pierre Grabar, director of the French National Cancer Research Institute, Paris, for contributions to the knowledge of the identity of proteins which have aided research in immunology and leukæmia

NATO Advanced Study Institutes Grants

The North Atlantic Treaty Organization is offering grants towards the organization of Advanced Study Institutes during 1964 The meetings, which may cover any scientific topic, should last for two weeks or longer and may take the form of practical experimental courses as well as the more usual type with lectures and discussions Grants may be used to cover, in whole or in part, the travelling and living expenses of visitors, costs of publication, etc Applications, which must be made before December 15, should be addressed to the Scientific Affairs Division, North Atlantic Treaty Organization, Place du Maréchal de Lattre de Tassigny, Paris 16, from which further information can also be obtained

University News

Aberdeen

N M Levy and Dr M A Lappin have been appointed to lectureships in electrical engineering and geology, respectively Dr W L Cunningham has been appointed to a research fellowship in biological chemistry

Bristol

Dr P J Randle, lecturer in biochemistry in the University of Cambridge, has been appointed to the newly established chair of biochemistry, and Mr J C Shepherdson has been appointed to a chair of pure mathematics in respect of his post as reader in mathematics in the University Both appointments will take effect as from April 1, 1964 The following appointments have also been made. *Lectureships*, Mr G A. Battersby (electrical engineering), Dr G I Fray (organic chemistry), Mr P M Keen (pharmacology), Dr J S Littler (organic chemistry), Dr T M Sutherland (chemical physiology) *Research fellowships*, Dr R R Hillier (physics), Dr J Malos (physics)

East Anglia

Mr M B Glauert, at present senior lecturer in the Department of Applied Mathematics in the University of Manchester, has been appointed professor of mathematics in the School of Mathematical and Physical Sciences Dr. N Sheppard, assistant director of research in spectroscopy and lecturer in chemistry in the University of Cambridge, has been appointed professor of chemistry in the School of Chemical Sciences Dr I Gibson has been appointed lecturer in biology in the School of Biological Sciences

London

Prof. C A Fisher, professor of geography in the University of Sheffield, has been appointed to the chair of geography (with reference to Asia), tenable at the School of Oriental and African Studies, from October 1, 1964 The title of professor of industrial and management engineering has been conferred on Prof S Eilon, in respect of his post at Imperial College of Science and Technology

Announcements

Mr E W Madge, of the Dunlop Rubber Co , Ltd , has been awarded the Colwyn Medal for 1963 of the Institution of the Rubber Industry, for his scientific and technological services to the industry Dr F H Cotton, head of the National College of Rubber Technology, London, has been awarded the Hancock Medal, for his services to the Institution and the rubber industry

The *Year Book of the Royal Society of Edinburgh, 1963*, covering the session 1961–62, includes, besides the obituary notices of Fellows, the proceedings of ordinary meetings, lists of recent awards, the accounts of the Society and the list of Fellows at October 22, 1962 (Pp. 144 Edinburgh Royal Society of Edinburgh, 1963 20*s* , 3 50 dollars)

Mr G L'E Turner, Museum of the History of Science, Broad Street, Oxford, writes "I am investigating the development of British microscopes in the nineteenth century For the investigation of the resolving power of some historical instruments I wish to have the use of a Nobert test plate and a Grayson rulings I am wondering if there is a reader in possession of one or other of these probe plates who would be prepared to lend it to me for this work If unable to lend such a plate, I should nevertheless be glad to hear of its whereabouts and any details of its construction and history "

A symposium on "Productivity in Research", arranged by the Institution of Chemical Engineers, will be held in London during December 11–12 The programme will include sessions on· the policy of higher industrial management, organization and interaction in research success, the effect of environment Further information can be obtained from the Institution of Chemical Engineers, 16 Belgrave Square, London, S W 1.

The third international congress on catalysis will be held in Amsterdam during July 20–25, 1964 The congress will be devoted to a discussion of the mechanism of heterogeneous catalysis, and papers will be presented on molecular description of the catalytic reaction and its intermediate states and selectivity in heterogeneous catalysis Further information can be obtained from the secretary of the congress, Dr D M Brouwer, P O Box 3003, Amsterdam

A symposium on "Treatment of Pain in Incurable Disease" will be held at Addenbrooke's Hospital, Cambridge on January 18 The programme will include researches on the action of phenol on nerve fibres, films of the treatment of spastic conditions with phenol, recent advances in the treatment of cancer pain, analgesic and other drugs in the treatment of chronic pain; the surgery of pain The fee for the symposium will be 1 guinea Further information can be obtained from the Secretary of the Medical School, Tennis Court Road, Cambridge

Erratum In an advertisement (*Nature*, 199, diii, 1963) of books published by the International Society of Plant Morphologists, Department of Botany, University of Delhi, Delhi 6, one title was erroneously given as *Plant Tissue and Organic Culture—A Symposium* For *Organic* read *Organ*

PARTICLE SIZE ANALYSIS AND FLOW OF POWDERS

THE second regional meeting on "Particle Size Analysis" was held on October 2 at the University of Sheffield under the auspices of the Whiting and Industrial Powders Research Council Like the first meeting at Hatfield, it attracted an audience of about 200 people from all parts of the country, and on this occasion one person from as far away as Norway There was also an opportunity of visiting a specially arranged exhibition of particle size analysis equipment, at which sixteen exhibitors displayed twenty-four instruments The day was divided into two sessions, particle size analysis being discussed in the morning and the flow of powders in the afternoon

The chairman of the morning session was Mr D C Soul, director of research of the Whiting and Industrial Powders Research Council The first lecture, by Dr B H Kaye, also of the Whiting and Industrial Powders Research Council, entitled "A Random Number Technique for Investigating the Accuracy of Microscope Methods of Particle Size Analysis", gave, as he himself said, the mathematically less-expert particle size analyst a 'do-it-yourself kit' for establishing the confidence limits to be placed in a given microscope particle count, or to compute the number of counts necessary to give a definite confidence The method depends on assigning numbers corresponding to those in the size classes of particles found or anticipated, then to obtain random numbers from tables or otherwise, and interpret each number as a particle Repetition of this process, involving no mathematics at all, allows a number of curves to be drawn, which will be enclosed by a 'scatterband' indicative of the purely statistical variations to be anticipated, but stripped of all experimental or operators' errors The technique was illustrated by discussions of several typical analyses A technique of 'stratified' sampling, in which the particles under test are divided into overlapping groups, which are counted separately and later recombined, was shown to give narrower confidence limits at no extra effort The questions dealt with the need for preliminary counts of unknown samples, 'homogenizing the results of the stratified groups to a unified whole, and the fact that the confidence limits of the whole, the average size, will be better than that of any particular group, which might be of interest, for example, for unwanted coarse material

The second lecture on "The Use of the Optical Microscope in Particle Size Analysis", by Dr V Timbrell, was read in his absence by three of his co-workers at the Pneumoconiosis Research Unit of the Medical Research Council and the Welsh School of Pharmacy Mr Reynolds described the electro-optical arrangements of the 'double image' microscope designed by Dr Timbrell, in which two images of the same particle are produced by a vibrating mirror The amplitude of vibration is adjusted until the images are just contiguous, when the particle diameter in the direction of vibration can be read from a calibrated meter Mr Cook discussed the advantages to be gained by this method, which lends itself to a certain degree of automation by comparison with the graticule method Dr Barnett amplified this theme and supported it with figures showing the vastly increased reproducibility in inter- and intra-operator comparisons, because the operator has only to find the position when two images precisely join, rather than estimate the sizes of irregular areas Up to 400 particles can be counted in 10 min The questions were concerned with the price and availability of the microscope, the need or otherwise to make sure of random orientation of the particles, the possibility of using a projection method or examining photomicrographs rather than slides, and methods of dispersing certain particles for mounting on slides Interesting answers to these latter questions suggested thixotropic liquids and, for completely three-dimensional random distribution, dispersing the particles in a thermosetting resin and eventually preparing a section

Dr J A Kitchener, of the Royal School of Mines, took the chair for the afternoon session During the first lecture, "The Flow of Powders", Dr J C Williams, principal lecturer in powder technology at the Bradford Institute of Technology, gave a series of demonstrations to show the segregation of powders by size when being filled into a hopper Fertilizer fractions differing 5 · 1 in diameter, the smaller particles being dyed green or black, segregated distinctly in the 'Perspex' containers and hoppers The effect is caused by the fact that the smaller particles cannot flow down the slope of the heap, which is dotted with excessively large 'potholes'. Hoppers with more nearly vertical walls exhibit this phenomenon less Similar demonstrations and slides showed the absence of flow at or near the hopper walls as they were emptied This means that all except monodisperse powders will unmix when being charged into or discharged from a hopper, a phenomenon serious enough to merit close attention The questions elicited a number of interesting facts—to name but one, that density and shape factors may also promote segregation, but in a conflict of factors, size is always predominant Some desegregation becomes noticeable at particle diameter ratios 1 1 2.

Mr R L Brown, deputy director of the British Coal Utilization Research Association, discussed "Angles of Friction and Sliding of Non-Cohesive Powders" The angle of repose is the steepest angle against the horizontal of a heap of material at rest, the angle of sliding is the angle to the horizontal of the interface between stationary and moving material of a bed of powder discharging through an aperture These angles depend not only on the material itself, but also on the geometry of the container and the manner of forming the heap, stress distributions are all-important, so that reproducible but mutually exclusive results may be obtained Departure of the particles from sphericity and the presence of fines tend to increase the angles In order to relate them to a more fundamental property, the angle of internal friction observed when a powder is sheared, is introduced; except against very rough surfaces, the angle of external friction is usually smaller Internal friction and sliding as shown by the crater above the circular discharge aperture appear to be related There are considerable differences in results derived from two- and three-dimensional surfaces, for example, in long, rectangular hoppers as against circular ones Questions concerned the coating of powders, which may aid flow by destroying aggregates, different forms of 'bridging' in hoppers, and the advantages (starting a movement) and disadvantages (compaction) of vibrators in hoppers

The last speaker of the day, Dr L Cohen, of Simon-Carves, Ltd , discussed "The Flow of Cohesive Bulk Solids" Rather than see how particle properties can be made to explain bulk properties, the lecturer described Prof Jenike's approach of considering the heap as a homogenous, isotropic, plastic material developing strength under its own compacting weight, a conception that has also been found fruitful in soil mechanics The principles of the Jenike shear cell, in which a compacted powder is sheared (*a*) across its bulk and (*b*) against a solid surface were explained The powder breaks down and begins to flow when its cohesive shear strength is exceeded The practical history of the powder (dampness, temperature, residence in the hopper) is of crucial importance, but given the right conditions of flow function can be derived which is an invaluable aid to hopper design, and which is capable of forecasting differences in flow behaviour of otherwise seemingly identical powders The questions dealt with the design of bunkers, the degree of standardization of Jenike's procedure and its applicability to damp and wet materials, the treatment of powders of very low bulk density (magnesium carbonate at 8–9 lb /ft ^{3}), mechanical aids to hopper discharge and the effects of flow-promoters

The meeting was closed with a vote of thanks to speakers, audience and organizers by Dr Kitchener, who also announced that preparations for a third regional meeting on powder technology topics in the spring were under way

TRANSPORT AND TRAFFIC NOISE

A SYMPOSIUM on "Transport and Traffic Noise" was held in the University of Southampton during September 27–28 The symposium, which was sponsored by the Society of Acoustic Technology and the Institute of Sound and Vibration Research of the University of Southampton, was attended by about 130 people representing various firms related to the motor industry, local government authorities, universities and colleges of advanced technology

The symposium was opened with a lecture by Prof E J Richards, the director of the Institute of Sound and Vibration, on the impact of the report of the Committee on the Problem of Noise, headed by Sir Alan Wilson Prof Richards, who was a member of the Committee, directed attention to the startling increase, which occurred between the 1948 and 1961 noise surveys, in the number of people who notice noise outside their homes—42 per cent in 1948 and 91 per cent in 1961 The statistics given in the report suggest that road traffic noise is largely to blame for this increase In fact, of the various external noises, 36 per cent of people questioned in 1961 found road traffic noise disturbing, compared with 9 per cent who were disturbed by aircraft noise Prof Richards discussed the findings of the Wilson Committee in general terms and described some of the recommendations which it had made

The second lecture was given by Dr B W Robinson (National Physical Laboratory) on the measurement of noise Dr Robinson outlined the various units which have been introduced for the measurement of noise and discussed the relation between the objective (db), the frequency weighted decibel (dbA), the unit of subjective assessment (phon), and the attempts which had been made by Stevens, Zwicker and others, to compute a single loudness figure which agrees closely with the phon Dr Robinson also discussed the standard practices which have been suggested for rating the noisiness of motor vehicles and which may soon be implemented by law

The afternoon session was devoted to two technical lectures, by Dr T Priede (C A V, Ltd, Warple Way, London, W 3) and Dr P O A L Davies (Institute of Sound and Vibration Research) Dr Priede discussed the subject of engine noise, with particular reference to Diesel engine noise, illustrating his talk not only with slides, but also with tape recordings, which proved to be a much more efficient means of showing the result of decreasing a noise by a few decibels Dr Priede discussed the mechanics by which noise was created in a Diesel engine and described some of the extensive investigations which have been carried out at C A V, Ltd, to reduce it Special mention was made of air-intake noise, the reduction in noise which may be obtained by smoothing the cylinder pressure, and the noise produced by resonance of the engine casing

In his lecture on silencer design, Dr Davies compared the results which may be obtained from the traditional acoustic theory of silencers, and the new shock wave theory which has been investigated by him and his co-workers at Southampton Single-pulse shock wave theory can be used in discussing an exhaust system, because for a typical four-stroke engine running at 3,000 r p m the primary pulses travel down the exhaust pipe at intervals of about 18 ft Dr Davies showed that the single pulse theory may be used to give a picture of the gas flow through the exhaust system, to calculate the back pressure, and to determine the attenuation which will be produced by the system The acoustic filter theory still has its place in the field of harmonic response, but the single pulse theory describes the transient response in a way the older theory could never do

The evening session of the conference consisted of an open lecture by Mr H Purkis, of the Building Research Station, on the subject of transport noise and town planning. Mr Purkis first directed attention to the way in which noise nuisance has been growing and is likely to grow in the future, owing to the tremendous increase in vehicle ownership and industrialization He then discussed some of the proposals which had been suggested for combating the nuisance in new towns Motor-vehicles could not be prohibited from a town without killing all commerce, and it could not be expected that the noise-levels which were to be laid down for cars would be able to counteract the increase in overall noise-level which would be produced by the increasing number of vehicles

Since overall noise-level must be expected to increase, means must be found to prevent the noise reaching houses, shops and offices Mr Purkis discussed sunken roads, smooth flowing motor-ways lined with specially insulated buildings to prevent the noise permeating to other dwellings, as well as some of the unsuccessful (that is, noise-producing) devices which were being used by traffic engineers to-day—one-way streets, which lead to faster, more noisy, traffic, and the use of side streets which distributes the noise to parts of the town which were previously quiet

On the Saturday morning, consideration was given to the problem of noise as it affects the passengers in a car The first lecturer was Dr G M L Gladwell (Institute of Sound and Vibration Research), who presented a review of the literature on the subject He paid particular attention to the noise caused by the passage of the tyres over the road, to the way in which this was transmitted through the car structure, and to the mechanical/acoustic properties of the passenger cabin He also stressed the need for more fundamental investigation into the vibration characteristics of a car, and the use of electronic analogue computers to make the investigation of the vibration characteristics of a projected design more logical and less a matter of guesswork In the extended discussion period following this review, representatives from Peugeot, Ford, Humber, Pirelli and Dunlop contributed from their own experience The discussion centred on the road noise problem M J Genestier, director of the Peugeot Research Laboratory, explained how they had devised the suspension system of their 404 model specifically for the Michelin *X* tyre, a tyre which excites vibration in a frequency-range much narrower than others, and had managed so to tune the suspension system that the vibrations that were excited were not transmitted to the car Other representatives stressed the need for car and tyre manufacturers to co-operate, and consider when designing a car the characteristics of the tyres which were to be fitted

Dr A Chiesa, from the Pirelli rubber laboratory in Milan, gave the next lecture on some experimental investigations which they had undertaken on the noise inside cars After a general discussion on the various origins of the noise, Dr Chiesa described the basic experimental method which is used The noise produced in a running car varies in intensity and in frequency content It must therefore be investigated by using statistical methods Most of the important information about the noise could be obtained from its frequency spectrum, and Dr Chiesa discussed the instruments which were used in the Pirelli laboratories to obtain this spectrum completely automatically He then showed how the various kinds of vibration could be distinguished by an inspection of the spectrum, illustrating his remarks with slides of typical spectra obtained by driving over various kinds of road Dr Chiesa again emphasized the importance of co-operation between car and tyre manufacturers, and described the kind of research programme they carry out when a certain manufacturer considers fitting one of their tyres

The final lecture of the symposium was on the subject of hovercraft noise and was given by Prof Richards He began by pointing out that hovercraft present an extremely difficult noise problem, much greater than that of conventional aircraft or helicopters They operate at ground-level, very often near to dwellings, their most likely means of propulsion is an airscrew, which is basically noisy, and at present they develop very high horse-power in a relatively flimsy structure Prof Richards went on to define the various noise sources—engines, propellers, fans, air jets, etc All these sources can generate noise, which in turn can produce resonances in the aircraft structure He then stressed that a fair estimate of the likely noise production of a hovercraft could not be obtained from prototypes, which inevitably were constructed from components already in use in aircraft, motor-cars, etc , and which were not designed specifically for hovercraft Provided that proper attention was directed to the components, the design of the hovercraft could undoubtedly be modified to minimize the noise that was generated Prof Richards directed attention to the fact that the noise problem for conventional aircraft was realized only when they had been in use for many years, but that, provided sufficient pressure was exerted on designers, it could and should be dealt with at an early stage of the development of hovercraft

Reports on the research work on which some of the lectures were based are to be published in forthcoming issues of the new *Journal of Sound and Vibration* (Academic Press, Inc , London, Ltd)

G M L GLADWELL

FUNDAMENTAL ASPECTS OF COMBUSTION

THE annual Coal Science Lecture of the British Coal Utilization Research Association was established in 1951 in the belief—to use the words of Sir Charles Ellis, then its president—"that a Research Association should in its own particular field play a part analogous to that of the great learned societies and should, in addition to applying knowledge and attempting to produce immediate results, also take its share of responsibility in the progress of the fundamental work of its subject" The previous Lectures, which have proved eminently successful, were given by eight leading British scientists and three from overseas Prof D. W van Krevelen (University of Delft), Monsieur R Cheradame (Centre d'Etudes et Recherches des Charbonnages de France). and in 1962, Mr H Seidl (Deutsche Babcock and Wilcox Dampfkesselwerke)

The twelfth of the series was delivered by Dr D T A. Townend at the Institution of Civil Engineers on October 16 Dr Townend, who was until 1946 Livesey professor of coal gas and fuel industries in the University of Leeds, retired as director general of the British Coal Utilization Research Association in September 1962 and, when inviting him to give the lecture, the Association's Council suggested that he should speak on a subject to which his earlier work on the fundamental aspects of combustion was relevant hence his title "Some Reflexions on Combustion"

Dr Townend said that, on reflecting on a suitable theme, he had been led more and more to appreciate how dominating an influence the combustion of the elementary combustibles, hydrogen and carbon monoxide, must play in the overall combustion and gasification of all solid fuels For coal was first pyrolysed to yield combustible gases, volatile hydrocarbons and coke, the primary combustible gases being hydrogen and methane, and at temperatures above 700° C, hydrogen was almost the sole product. Carbon monoxide was the primary product of the oxidation of coke and the volatile hydrocarbons yielded on pyrolysis ultimately hydrogen and carbon Finally, even hydrocarbons were first transformed essentially into carbon monoxide and hydrogen before their overall combustion was completed Some 30 per cent of the potential heat in coal was released during the production of carbon monoxide by the direct oxidation of carbonaceous material, and the remainder was released from the combustion of carbon monoxide and hydrogen The presence of hydrogen and carbon monoxide in the combustion gases within a pulverized-fuel-fired furnace was illustrated from the present work of the International Flame Foundation at Ijmuiden

Dr Townend next directed attention to the important part played by hydrogen and oxygen atoms in the chain mechanisms inherent in the combustion of hydrogen and carbon monoxide, in flames their concentrations were greater than would be expected from theoretical considerations The presence of hydrogen atoms was readily demonstrated by the phenomenon of candoluminescence whereby certain activators (for example, oxides of bismuth, manganese and lead) added to the oxides of host materials (for example, calcium, strontium and barium) cause a characteristic light emission (fluorescent spectra) when brought in close proximity to the flames of hydrogen-containing combustibles The hydrogen atoms recombine, however, in the presence of diluent gases and at critical diluent concentrations the light emission is repressed Moreover, at the point of the repression (*a*) the flames of hydrocarbons are rendered non-luminous, and (*b*) in the presence of sodium salts the yellow *D*-line emission is also quenched In further illustration of the part played by hydrogen atoms and their recombination by molecular collisions or on surfaces, it was shown how the heat conduction from a hydrogen flame to a surface was 20 per cent greater than that from a fairly dry carbon monoxide flame, although the calorific values are much the same

The presence of oxygen atoms in carbon monoxide flames had been established some years ago in connexion with work on boiler availability, and there was little doubt that they were mainly responsible for the oxidation of sulphur dioxide to sulphur trioxide with the ultimate formation of sulphuric acid

Another important problem concerned with the combustion of carbonaceous fuels was the presence of chemisorbed layers on the fuel surface At low temperatures, an unstable carbon–oxygen–water-complex (peroxygen) controlled the oxidation of the coal substance, at about 70°–80° C its breakdown could lead to rapid oxidation and with certain fuels to spontaneous ignition At combustion temperatures the presence of a layer, defined as oxycarbon, was an important factor in the combustion process

Reviewing the overall picture, Dr Townend pointed out that in the practical field a matter of importance was the control of the aerodynamics of a combustion system to provide adequate mixing of solid particles with the reactant gases, including hydrogen, carbon dioxide, water and atoms and radicals, for gasification and oxidation were mutually involved He also considered the likely advantages to be gained by combustion under pressure, having regard to the chemical and physical factors involved

In conclusion, Dr Townend emphasized that many combustion phenomena accepted to-day as commonplace would not have been predicted forty years ago, and as an illustration he mentioned the manner of his discovery of the two-stage process of the ignition of hydrocarbons which had proved the key to the elucidation of the problem of 'knock' in internal combustion engines

After the lecture a dinner in honour of Dr Townend was held at the Savoy Hotel, at this function the Coal Science Medal was presented to Dr Townend by Mr E H. Browne, president of the British Coal Utilization Research Association

A CHANNEL LINK

ALTHOUGH the report of the working group of British and French officials on *Proposals for a Fixed Channel Link*[*] was published two months later than the Broadsheet *Transport in the Common Market*, issued by Political and Economic Planning in July[†], it is significant that in the Broadsheet Mrs Trench makes no reference at all to either a tunnel or a bridge for the English Channel After indicating the three objectives of a common transport—removal of obstacles which transport would offer to the establishment of the general Common Market, creation of healthy competition of the widest possible scope, provision of means of transport meeting in quantity and in quality the requirements of the European Economic Community—the Broadsheet reviews the measures proposed These include a tariff policy for freight, and after considering the general proposals the Broadsheet considers international transport by road and the domestic road transport of goods

The investigation finds that there is still no sign of an agreement between member States on the proposals or even of the policy being implemented in 1963–65, and it is unlikely that there will be any substantial progress towards implementing a common policy until after this The proposals in the Action Programme for the Common Transport Policy presented to the Council of Ministers in May 1963 are themselves the result of compromises between conflicting objectives of the policy and also between existing practices in the member States, they are so framed that they stand some chance of being acceptable to all the countries in spite of the differences between their present transport systems The objectives of the policy are much more ambitious and extensive than the minimum necessary to secure the free working of the Common Market, and the instruments chosen, notably the system of forked tariffs, have far-reaching implications Nevertheless, some of the major transport problems are left untouched Own-account transport of goods is left free to develop in a way which could well frustrate the objectives of the policy to secure an optimal use of transport facilities of the Community as a whole There are no proposals about private cars, although the growth in their numbers and the pattern of their use affect road expenditure and traffic congestion, and thus the cost of operating goods vehicles, as well as the passenger revenue of the railways, the size of the railway system and its costs of provision

Any attempt to secure a real improvement in a community's use of transport resources should, the Broadsheet points out, rest on a full investigation of the social benefits and costs of transport operations, and the Commission is at present studying 'infra-structure costs' in order to reconstruct the basis of taxation on different forms of transport to redistribute the burden of Government expenditure as between different users It is suggested that the Commission should broaden these investigations to take into account costs and benefits dispersed among the community as a whole as a result of the expansion or contraction of different kinds of transport Policy could then be based on a much better knowledge of what different developments are likely to cost the community in terms of lost amenities, increased congestion, reduced scope and frequency of public services, etc

This kind of consideration is lacking in the report on the proposals for a Channel tunnel and Channel bridge Unfortunately, the report is also markedly lacking in either imagination or enthusiasm, and it appears to be preoccupied with financial and economic considerations in the narrower sense to the exclusion of social and political and even technical aspects whether short or long term Charged with considering the project for a tunnel proposed in March 1960 by the Channel Tunnel Study Group and the project for a bridge proposed in October 1961 by the Channel Bridge Study Group, its findings are in favour of the rail tunnel project It finds this means satisfactory from the technical point of view and constituting from the economic point of view a preferable solution to the continued use and development of established means of transport, while at the same time being free from the practical disadvantages of the bridge—which is likely to have a capital cost almost double The working group foresees no increase in traffic or other advantage to offset this higher cost, and even the financing of the rail tunnel it regards as an uncertain risk and recommends that the two Governments should contemplate direct guarantee of loans, but also that the bounds of the privately owned undertaking should be guaranteed This would be a new departure in United Kingdom practices and one that in France is only used on an extremely limited scale

It is recognized that the bridge, which offers a continuous road and rail Channel link in the open, is a more attractive proposal to road users than the tunnel project, in which vehicles are driven on and off special car ferry trains operating at intervals of 5–30 min according to demand, carrying either 150 or 300 cars, and completing the journey in an average of 65 min, of which 45 min would be occupied by the journey proper The working party regards the bridge as offering a new and serious hazard and source of delay to shipping, also its construction would involve international agreement as to safety regulations for sea traffic as well as to the bridge in principle It does not consider that these objections would be removed by foreseeable developments in navigational aids within the next few years However, it did not seriously consider a third proposal, for an immersed road-rail tunnel, which was submitted in March 1963 and for which the capital cost is estimated to be £236 million, compared with £329 million for the bridge and £160 million for the rail tunnel

[†] *Planning*, Vol 29, No 473 (8 July, 1963) *Transport in the Common Market* Pp 223–286 By Sylvia Trench (London Political and Economic Planning 1963) 6*s*

The proposals for a bridge and for a road tunnel both rely largely on tax reliefs to improve the financial prospects of their respective projects, but the risks do not appear to be excessively high, and while the means of Government assistance here proposed may be open to objection, the decision as to whether the project should be supported or not is one for Government level The decision, moreover, is urgent and ought not to be postponed If the determining considerations are those that fall outside the scope of the working party itself, and even if the proposals represent little that could not have been advanced half a century or more earlier, to delay is only to increase the ultimate cost of a favourable decision—a cost that has multiplied many times since the proposal was first advanced in the last century (see, for example, *Nature*, 1, 160, 303, 631, 1869)

EMPLOYMENT OF WOMEN IN INDUSTRY

A RECENT investigation of the industrial employment of women throughout their middle working lives*, to which the Director of the Nuffield Foundation contributes a foreword, is essentially in continuation of the investigations which the Foundation has for some time been promoting on the employment prospects of older men Insisting that the basic unit of society is the indissoluble complex of relationships that controls both men and women, Mr Le Gros Clark takes account of this subtle but changing element in dealing with the influx of women into employment. Considering first the life rhythms of modern women he concludes that there will be far fewer single women in middle life and a diminishing number of widows, though this large impact of widowhood will not be felt until most married women are passing beyond their employable age Of necessity, if employers still need female labour, they will have to depend on married women, and mostly on those of mature years Moreover, Mr Le Gros Clark insists also on the importance of the contribution which married women and mothers make outside the labour market, he regards as misleading the classification of many women by economists as merely 'dependants' Women as a whole are not free to go out to work until they feel that they have among them accounted for their multifarious domestic and family commitments

His analysis of available and relevant figures of part-time employment indicates that age makes remarkably little difference in the opportunities most women have of limiting the hours they work, and that the older women still have their domestic commitments as well as some impairment of health in mind when they stipulate for a part-time job Most of them would also seem to take it for granted that at their age they may have to gravitate to a catering. domestic or cleaning job Now that working hours per week are contracting in most industries, the stipulations made by many married women seem likely to appear more realistic It is not easy to say at what ages and for what reasons women finally move out of the labour market, but, in the present state of medical knowledge, women seem more susceptible than men to the kinds of ailment which one might expect to hasten their withdrawal from work outside their homes

Their rates of withdrawal from the manufacturing industries are most noticeable, and while the possibility of moving the older married women to lighter or modified work requires examination, it can at least be said that, although most middle-aged women are not on such exacting work, the differential withdrawal rate among those who are could easily affect the average rate at which women leave employment At present they do so in substantial numbers in their early fifties, and probably nearly one in three has departed by the time they approach sixty Some leave by choice and some subject to retirement regulations, but a proportion which is not negligible complain of industrial strain or incipient ill-health, so that women still at work in their late sixties represent only about a quarter of those who are at work ten years younger, and most are working on their own or managing the work of others, or in some 'domestic' form of employment

Mr Le Gros Clark suggests some of the female–male adjustments that are likely to be needed particularly if middle-aged married women are required in employment In large measure he predicts they will be able to make their own terms, particularly about their hours of work This is likely to be felt particularly in health, welfare and educational services, but he suggests too that the amenities, the codes of behaviour and the conventions habitual through industry are likely to be affected ultimately He points to the desirability, in the general education of girls, of making an effort to break down the barrier between the sciences and the arts and of stressing the æsthetic qualities of the former subjects This is largely a matter of finding imaginative teachers, but it has a great bearing on equipping girls for life, especially as, ultimately, married women may have to show themselves more prepared to take on posts of skill and responsibility

SCIENTIFIC RESEARCH IN BELGIUM

THE annual report for 1962 of the National Council for Scientific Policy, Brussels*, is of special interest in view of the present discussions on scientific policy in Western Europe generally Moreover, it exemplifies the type of report which the Office of the Ministry for Science might be expected to provide regularly for the United Kingdom and which, on a lesser scale, the annual report of the Advisory Council on Scientific Policy has sometimes supplied in part Following an introduction, the report is in two parts the first outlines the functions of the Council, including the general structure of scientific work in Belgium, the second records the activities of the Council during December 1, 1961–December 1, 1962, including those of its committees and institutions and Government measures affecting the work of the Council Among appendixes which list the membership of various committees, etc, is a note on the meeting of the Ministerial Committee for Scientific Policy and the Bureau of the Council last July at which the Budget for 1963 was fixed at 4,904 million francs, a 20 per cent increase on the previous year, and including an 18 per cent increase for the universities

The first part of the report is of the most general interest The budget for 1962 was for 4,080 million francs, an increase of 14 4 per cent over 1961 Of this, 2,316 million francs were for education, 1,156 million francs for economic interests, 179 million francs for agriculture, 153 million francs for defence (a decrease of 9 per cent) and 77 million francs for public health By institutions the distribution of the budget is as follows (figures in brackets give the percentage increase on 1961) universities and other higher educational institutions, 2,434 million francs (11 2), State scientific establishments, 748 million francs (11 7), public service institutions supported by the State, 627 million francs (27), industrial enterprises and co-operative centres, 170 million francs (16 4), and international organizations, 101 million francs (– 6 5) By sciences, etc, the distribution is as follows fundamental research, 533 million francs (16), of which 221 million francs was for the exact sciences, 114 million francs for biology and other natural sciences, and 80 million francs for the medical sciences, 601 million francs for applied research (18), of which 276 million francs was for agriculture and veterinary medicine and 325 million francs for industrial research, 826 million francs for nuclear science (19 7) and 120 million francs for economic and social science (33 3)

---

* Conseil National de la Politique Scientifique Rapport Annuel, 1962 Pp 171 (Bruxelles Conseil National de la Politique Scientifique, 1963)

The second chapter of this first part of the report analyses further the research effort as supported by the Foundation for Scientific Research, and in special fields such as nuclear energy and space research, for which 14 8 million francs was allocated among four groups Fifteen groups working on molecular biology received 26 million francs, six on medical enzymology, 3 million francs, and seven on human genetics, 4 5 million francs Information regarding the universities, similar to, but less detailed than, that supplied in the annual returns from the University Grants Committee, is contained in the following chapter, which also includes figures for the support and staff of national scientific institutions Student numbers at the four universities of Ghent, Liège, Brussels and Louvain have risen by 23 7 per cent since 1958 to 28,346 in 1962, and other institutions of higher learning bring this total to 32,726 University grants have increased in the same period from 646 to 1,336 5 million francs

STRYCHNINE-RESISTANT CENTRAL INHIBITION

Strychnine-resistant Inhibition in the Brain

In the spinal cord it has been shown that strychnine very effectively depresses the activity of the postsynaptic inhibitory synapses which are formed by a variety of pathways converging on motoneurones[1–4] Strychnine depresses the inhibitory action of the olivo-cochlear bundle on sensory fibre terminals and on the hair cells of the organ of Corti[5] Since this alkaloid has this specific depressant action on so many types of inhibitory synapses it has been suggested that it acts competitively against the same inhibitory transmitter substance[6] Large and prolonged inhibitory postsynaptic potentials (IPSPs) have been recorded from a variety of neurones in the higher centres of the brain pyramidal cells of the motor cortex[7–10], of the sensory cortex[11–13] and of the hippocampus[14,15], and also mitral cells of the olfactory bulb[16], cerebellar Purkinje cells[17,18] and thalamic neurones[19–21] If there is the same inhibitory transmitter at all these synapses, it would be expected that strychnine would similarly be a very effective depressant

However, Green, Mancia and Baumgarten[22] and Baumgarten, Green and Mancia[23] found that strychnine failed to block the inhibition of mitral cells and cells of the plexiform layer of the olfactory bulb in response to stimulation of the lateral olfactory tract and of the anterior commissure In the investigation reported here it is shown that strychnine is without any detectable effect on three examples of postsynaptic inhibition in the brain even when given in doses that virtually eliminate postsynaptic inhibition in the spinal cord

Adult cats were anæsthetized by pentobarbital sodium and intracellular recordings made by glass microelectrodes filled with solutions of 3 M potassium chloride (5–40 MΩ) or 2 M potassium citrate (7–30 MΩ) Microelectrodes filled with 4 M sodium chloride (1–4 MΩ) were usually used for extracellular recording

In Fig 1*A* are the intracellular and just extracellular records from a hippocampal pyramidal cell in response to stimulation of the fimbria hippocampi Subtraction of these two records reveals that the pyramidal cell had responded by a typical large and prolonged inhibitory postsynaptic potential In Fig 1*B* it is seen that 10 min after the intravenous injection of 0 3 mg strychnine hydrochloride per kg body-weight a similar inhibitory potential was evoked in another pyramidal cell close to the first Postsynaptic inhibitory potentials of comparable amplitude and duration were observed in 174 out of 178 impaled hippocampal cells in strychnine-free preparations and

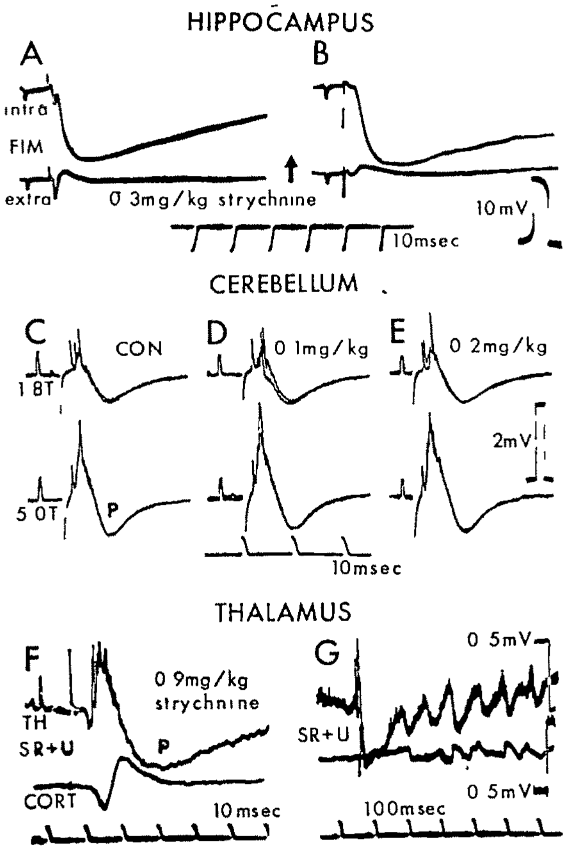

Fig 1 *A*, inhibitory postsynaptic potential from hippocampal pyramidal cell, produced by fimbria stimulation (*FIM*) *B*, similar inhibitory potential after intravenous injection of 0 3 mg strychnine hydrochloride per kg *intra*, intracellular, *extra*, extracellular recording In *A* and *B* positivity is upwards, in *C–G* positivity is downwards *C*, responses evoked by stimulation of parallel fibres at 1 8 and five times threshold (upper and lower traces) and recorded from the layer of Purkinje cell bodies in the cerebellum A negative wave with spike discharges is followed by a positive wave (*P*) which is associated with an inhibitory hyperpolarization of the cell-body membrane (ref 18) *CON*, control response before strychnine *D* and *E* are similar responses after intravenous injection of 0 1 and 0 2 mg strychnine hydrochloride per kg, respectively *F*, responses recorded from the ventrobasal complex of the thalamus (*TH*) and the post-cruciate gyrus (*CORT*) in response to a combined volley in the contralateral superficial radial (*SR*) and ulnar (*U*) nerves after intravenous injection of 0 9 mg/kg strychnine hydrochloride Both the thalamic positive wave (*P*) in *F* and the repetitive *P*-waves in *G* are associated with large inhibitory postsynaptic potentials (refs 20, 21) and are resistant to this large dose of strychnine

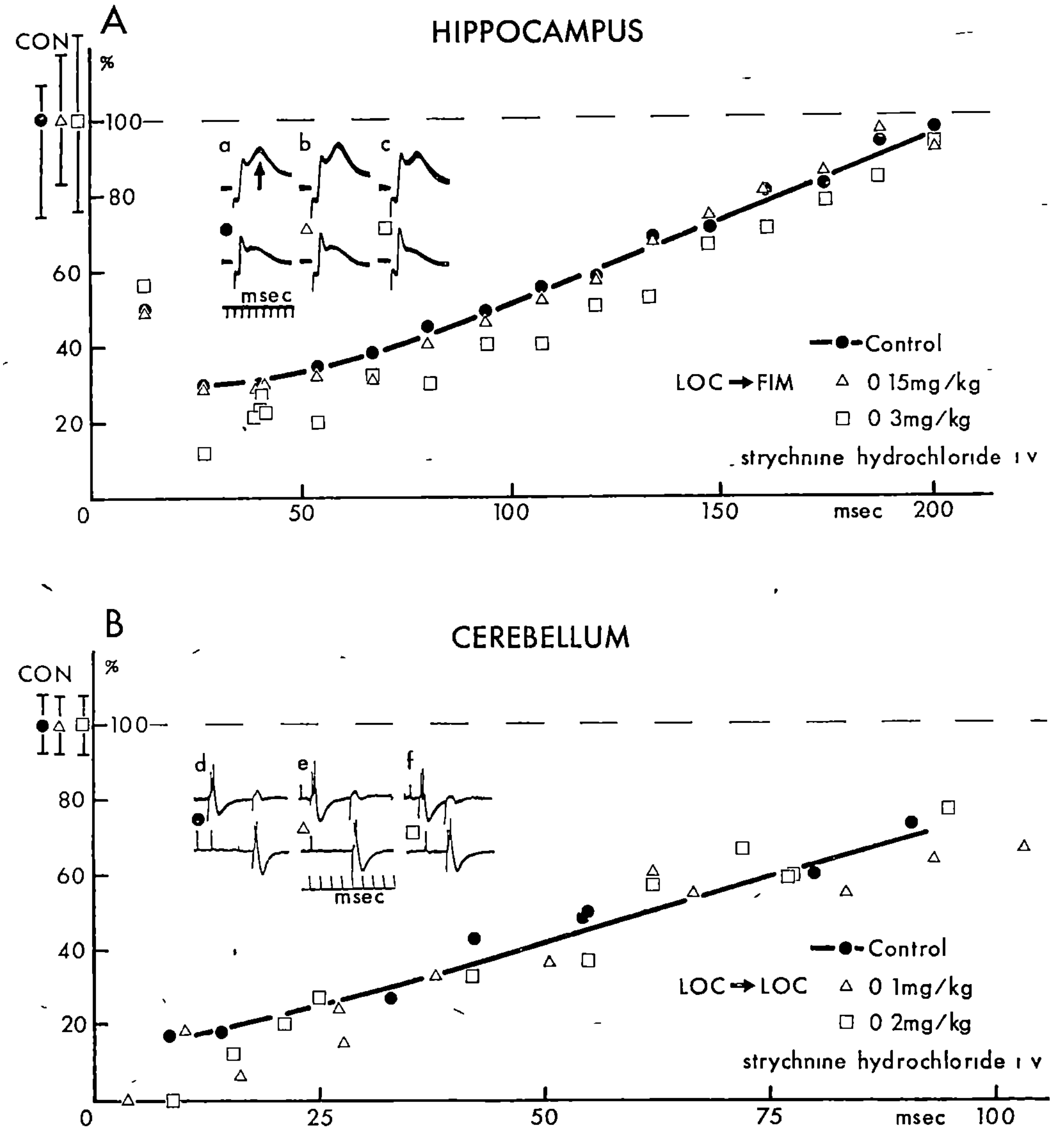

Fig. 2. *A*, upper traces in inset records are surface hippocampal responses to stimulation of fimbria. The first deflexion is due to antidromic invasion of pyramidal cells, the second (arrow) to synaptic excitation of these cells. The lower traces are the responses to the same test stimulus preceded 42 msec earlier by a conditioning local volley (*LOC→FIM*)—*a* is the control response, *b* and *c* are taken after intravenous strychnine injections. Symbols and doses indicated on the right in the figure. In the graph the size of the synaptically evoked pyramidal cell response to test volley is plotted against the conditioning-test interval. The inhibition lasts for about 200 msec and is unaltered by strychnine in doses up to 0·3 mg/kg. *B*, upper traces in insets show inhibitory effect of parallel fibre stimulation on the response of cerebellar Purkinje cells to a second and similar stimulus (*LOC→LOC*). Lower traces are test responses only. *d* is the control response, *e* and *f* the responses after strychnine administration. Symbols and doses indicated to the right. In the graph, the size of the negative wave is plotted against conditioning-test interval. Inhibition lasts more than 100 msec and is unaffected by 0·2 mg/kg strychnine hydrochloride. *CON*, control value, vertical bars indicating the scatter.

in every one of the 25 cells impaled after intravenous strychnine administration in doses of 0·3 mg/kg or higher.

In the cerebellum strychnine is likewise without action on the large extracellular positive potentials (Fig. 1*C*, *D*, *E*) which are produced by postsynaptic inhibitory action on Purkinje cells and recorded just outside the cell bodies[18]. Similarly, in the thalamus the large inhibitory postsynaptic potentials in the relay cells of the ventrobasal complex have as their counterparts large positive waves (*P*-waves) extracellularly[20,21]. Fig. 1*F* shows that the initial part of the *P*-wave set up by a large cutaneous volley was present and of normal size after a total dose of 0·9 mg/kg of strychnine, and in Fig. 1*G* there was still the normal series of rhythmic *P*-waves with associated burst responses. The intracellularly recorded counterpart of this response pattern is a series of large IPSPs.

In the hippocampus and the cerebellum strychnine also does not depress inhibitory actions such as those displayed in Fig. 2. In Fig. 2*A* the upper row of the insets show hippocampal surface records of responses to fimbrial stimulation. The first deflexion is a sign of the antidromic invasion into pyramidal cells, whereas the second wave denotes the synaptic activation of the same neurones. The lower row illustrates the effect of a local shock preceding the fimbrial stimulation by 42 msec, *a* gives the results before, and *b* and *c* after, the intravenous injection of 0·15 and 0·3 mg/kg strychnine hydrochloride, respectively. The graph in Fig. 2*A* is a plotting of the sizes of the synaptically evoked deflexion to fimbria stimulation against the time after a local stimulus, measured in per cent of the control value. The filled circles show the results before the strychnine administration, the open triangles after 0·15 mg/kg, and the open squares give the results after 0·3 mg/kg strychnine hydrochloride. Fig. 2*B* is a similar plotting for the cerebellar inhibition. The response here is the second of two potentials evoked by local stimulation of the parallel fibres about 2 mm from the recording electrode The latter was situated at the Purkinje cell body layer and picked up the *P*-wave associated with the inhibitory postsynaptic potential (cf Fig 1*C*, *D*, *E*) Filled circles give the control responses, open triangles the responses after 0 1 mg/kg and open squares the responses after 0 2 mg/kg strychnine hydrochloride The insets *d*, *e* and *f* show the inhibition of the second response after the same doses respectively The upper traces show the inhibition of the test response, the lower traces are the test responses alone Neither in the hippocampus nor in the cerebellum inhibitory curves is there any trace of a depressant action by strychnine Crawford, Curtis, Voorhoeve and Wilson (following communication) have also found that strychnine has no depressant action on inhibition of spontaneous or drug-induced repetitive firing of Purkinje cells, nor on the inhibition of sensimotor pyramidal cells following antidromic stimulation of the pyramidal tract

Our conclusion is that the powerful inhibitory action on hippocampal pyramidal cells, cerebellar Purkinje cells and ventrobasal thalamic relay cells is resistant even to large doses of strychnine.

It does not seem possible that this failure of strychnine action can be due to blockage by the blood-brain barrier There is ample evidence that the strychnine administration is having a convulsant action at the higher levels of the brain For example, in our experiments there was an increased rate of spontaneous discharge of cells, an augmented background noise and a large increase in the potential waves recorded from the surface of the cerebellum and hippocampus

Thus, there seem to be just two possible explanations for the failure of strychnine action on the inhibitions investigated One is that the transmitter or transmitters responsible for the inhibition examined in these higher centres are different from that which produces strychnine-sensitive postsynaptic inhibition in the spinal cord and the cochlea The other possibility is that the inhibitory transmitter may be the same in all areas mentioned, but receptor sites of the subsynaptic membrane may differ between the various parts of the nervous system Consequently, strychnine may differ in its effect on account of the effectiveness of its competitive attachment to the receptor of the inhibitory synapses on various nerve cells

The strychnine-resistant postsynaptic inhibitions are remarkable for the long duration of the unitary IPSPs and also for the potency of the IPSP Possibly these features are related to the strychnine-resistant property For example, they may arise either because there is a different inhibitory transmitter that is much more efficient or because the transmitter receptor sites react much more effectively Furthermore, the large size of the hyperpolarization suggests that conductance for K^+ ions plays a much larger part than with inhibitory actions on motoneurones[24] However, with all these IPSPs there is also an increased Cl^- ion permeability It will be appreciated that many of the strychnine-resistant inhibitions reported in the literature are due to pre-synaptic inhibition[25]

Strychnine and Cortical Inhibition

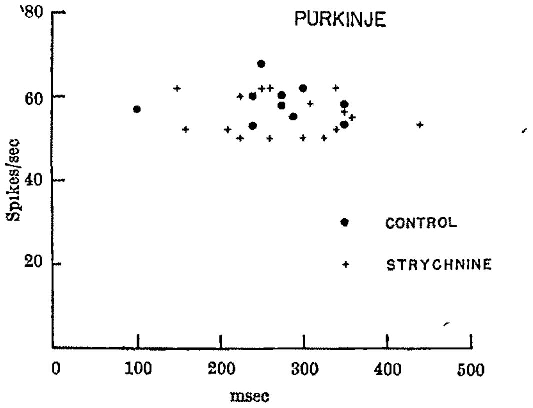
In view of the potent depressant action of strychnine on the postsynaptic hyperpolarizing inhibitory potentials of spinal motoneurones[1], it has been assumed that the enhancement of evoked potentials of the cerebral cortex which is produced by topically administered strychnine is associated with the depression of similar inhibitory potentials of cortical neurones[2] However, strychnine, which also augments the evoked potentials of the cerebellar cortex[3], has been shown not to block the prolonged hyperpolarizing potentials of Purkinje cells which result from local stimulation of this cortex[4] An investigation has therefore been carried out to determine the effect of this alkaloid on the inhibitions of Betz cells in the pericruciate cortex and of Purkinje cells in the vermis of the feline cerebellum

All experiments were performed on artificially respired cats which were anæsthetized with either 'Dial' or pentobarbital sodium, and paralysed with gallamine triethiodide Extracellular spike potentials of single neurones were recorded by means of the central barrel of five-barrelled micropipettes[5] and were photographed from an oscilloscope The cells were excited by the electrophoretic ejection of DL-homocysteic acid from one barrel of the multi-barrelled micropipette[5], and the duration of inhibition which resulted from an appropriate stimulus was measured as the period of suppression of this amino-acid-induced, or the spontaneous, firing The duration of this suppression of firing of both Purkinje and Betz cells was usually inversely related to the pre-stimulus rate of firing, which was varied by suitable adjustment of the electrophoretic current used to eject DL-homocysteic acid

Purkinje cells were identified by the position beneath the surface of the vermis the response to stimulation near the ipsilateral fastigial nucleus and the depression of spontaneous or induced firing which followed electrical stimulation of the surface of the cerebellar cortex within 1–2 mm of the recording site[4] This depression has been shown to be associated with an intracellularly recorded hyperpolarizing inhibitory postsynaptic potential[4] Betz cells were identified by the depth beneath the cortical surface (pre- and post-cruciate) and by the responses evoked by single and tetanic stimulation of the exposed pyramids[6] The spontaneous and amino-acid-induced firing of these cells was suppressed by repetitive stimulation of the pyramids (6 impulses, frequency 100/sec) which produces a hyperpolarizing inhibitory postsynaptic potential of Betz cells[6] ('recurrent' inhibition), and by stimulation of the cortical surface 3–4 mm from the site of recording[7].

Fig. 3 (upper) illustrates results from a Purkinje cell which was discharging spontaneously at a rate of approximately 55 spikes/sec. The control points (●) demonstrate that there was a considerable variation in the period of inhibition produced by local cortical stimulation at an interval of 2 sec. 3 min after 0·33 mg/kg of strychnine hydrochloride had been injected intravenously there was no change in the spontaneous firing rate and no significant alteration in the period of surface-evoked inhibition (+). Strychnine increased the spontaneous firing rate of other cells, possibly as a result of actions elsewhere in the nervous system[3], but nevertheless an examination of the period of inhibition with respect to this new firing rate, and to even higher rates produced by DL-homocysteic acid, failed to demonstrate any significant alteration in the relationship between firing frequency and the duration of inhibition. Similar experiments have shown that picrotoxin (0·9–1·1 mg/kg) and pentamethylene-tetrazol (80–90 mg/kg) are also without action on the afore-mentioned type of cerebellar inhibition.

Fig. 3 (lower) plots a curve for the depression of firing of a Betz cell by stimulation of the ipsilateral pyramid before (●) and 15 min after (+) the intravenous administration of 0·6 mg/kg of strychnine hydrochloride. This figure shows clearly that the relationship between firing frequency and the period of depression was unaltered by strychnine. Similar results were observed with the depression of firing produced by local cortical stimulation, both this and 'recurrent' inhibition of Betz cells were unaffected by doses of strychnine as high as 1·0 mg/kg.



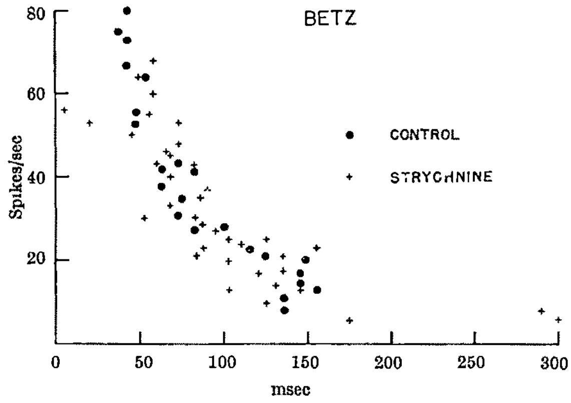


Fig. 3. Upper, duration of surface-evoked inhibition of a Purkinje cell plotted in relation to the spontaneous firing frequency (spikes/sec) before (●) and after (+) the intravenous administration of 0·33 mg/kg of strychnine hydrochloride. Lower, duration of the 'recurrent' inhibition of a Betz cell, evoked by six stimuli (100/sec) applied to the ipsilateral pyramid, plotted in relation to the frequency of firing (spikes/sec) elicited by the electrophoretic ejection of DL-homocysteic acid. Before (●) and after (+) 0·6 mg/kg of strychnine was administered intravenously

These results confirm that the inhibition of cerebellar Purkinje cells resulting from stimulation of the parallel fibres, and which is presumably mediated by the basket cells[4], is resistant to doses of strychnine which are more than adequate to suppress the postsynaptic inhibitions of spinal motoneurones. In addition, the 'recurrent' inhibition of Betz cells, and the inhibition of these cells produced by local cortical stimulation, are also apparently resistant to strychnine. A recent report[8] suggests that in unanæsthetized cats strychnine does block the 'recurrent' inhibition of Betz cells, but the method by which this inhibition was tested, using the invasion of a Betz cell by an antidromic volley, was probably not rigorous enough to permit a distinction to be made between the blockage of inhibition by strychnine and an increase in the background excitatory synaptic drive on the neurone.

Since it is possible that strychnine blocks spinal postsynaptic inhibition by preventing the access of the responsible transmitter substance to the appropriate sub-synaptic receptor sites[1], it may be proposed that this transmitter, presumably common to all strychnine-sensitive inhibitions, differs from the transmitters responsible for the strychnine-resistant postsynaptic inhibitions of cerebral, cerebellar, olfactory[9], thalamic[4] and hippocampal[4] neurones. Alternatively, one substance could be a common transmitter for all these various postsynaptic inhibitions, but, because of differences in nature of sub-synaptic receptors, this substance is blocked by strychnine at some synapses and not at others. It may be pertinent in this respect that in contrast to most forms of spinal postsynaptic inhibition, the hyperpolarizing inhibitory potentials of olfactory, thalamic, hippocampal, cerebral and cerebellar neurones are of prolonged duration. Furthermore, tetanus toxin, which presumably blocks the release of spinal inhibitory transmitters[1], reduces the 'recurrent' inhibition of evoked cortical activity[10], an observation which suggests that there are similarities between spinal and supra-spinal inhibitory transmitters. Preliminary experiments in which electrophoretically administered strychnine excited Purkinje cells provide an explanation for the excitatory action of this substance when applied to the cerebellar cortex[3]. A similar mode of action could account for the action of strychnine on neurones within the cerebral cortex. Alternatively there may be other forms of inhibition operating on cerebral and cerebellar neurones, apart from those studied here, which are sensitive to strychnine.

CHANGES IN THE ESTERASES OF RAT BRAIN AND BLOOD SERUM FOLLOWING ACUTE CRANIAL EXPOSURE TO X-RAYS

By Dr. E. B. MASUROVSKY and Dr. C. R. NOBACK

College of Physicians and Surgeons, Columbia University, New York

THERE have been increasing reports, in recent years, of significant changes in the activity of certain esterases of the nervous system, and other important regulatory systems throughout the body, which result from acute cranial and/or whole-body exposure to X-rays and other ionizing radiations.

Zeaman *et al.*[1] have presented histochemical evidence of increased esterase activity in the brain tissue of mice 2–10 days after cranial irradiation with a 1-mm beam of 20-MeV deuterons at doses ⩾ 16,000 rads. They attributed this esterolytic activity to Type-*C* cathepsins activated in, and/or released from, the lysosomes within radiation-damaged cells. Cholinesterases (especially cholinesterase II), on the other hand, have been found to exhibit decreased activity in the tissues and blood serum of a variety of mammalian species following irradiation with X-rays[2,3]. The assay procedures utilized in these investigations, however, were not suitable for detecting changes which might have occurred in the individual enzyme forms which constitute a given esterase system. Such changes may be demonstrated by the application of high-resolution zone electrophoresis in combination with selective multi-substrate and inhibitor characterization of the esterase components of the resulting zymogram patterns. This analytical approach was utilized in the experiments reported here, concerning changes in the esterases of the central nervous system and associated hæmato-circulation of the rat, following localized X-irradiation of the brain.

Brain homogenates and blood sera were prepared from mature ♂ Long-Evans rats, exposed to 20,000 r. of collimated 184-kVp. X-rays (generated at 30 m.amp, filtered with 0·28 mm copper plus 0·50 mm aluminium, half-value layer = 0·67 mm copper) delivered to a 30-mm² area of the right visual cortex 48 h prior to sampling. The dose rate was approximately 300 r./min in air as measured with a calibrated Victoreen r.-meter, model 570.

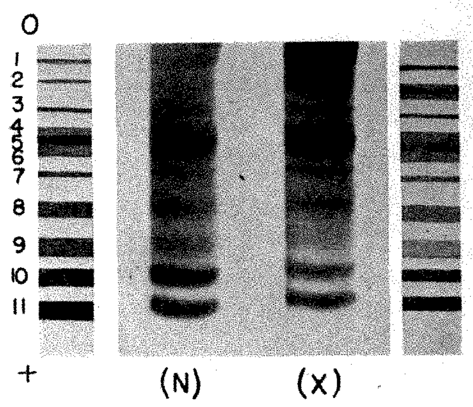
The animals (irradiated and normal controls) were killed by bleeding after relaxation under light ether. The blood thus obtained was allowed to clot at 20° C for 3 h, and the serum pipetted into centrifuge tubes for clarification. The brain of these animals was immediately perfused clear of blood under syringe pressure with > 500 ml. of a 0·9 per cent sodium chloride–2·4 per cent gum acacia solution at body temperature. It was then quickly excised from the cranial cavity and frozen solid with dry ice.

A cylindrical core, corresponding to the 30-mm² circular area exposed to the collimated X-ray beam (2·5 g), was removed from the right irradiated half and left control half of the brain, and individually minced in a glass—'Teflon' pestle homogenizer using normal saline at a 1 : 1 proportion with brain tissue. Alternate mincing and rapid freezing–thawing were performed six times before pipetting the homogenate into centrifuge tubes for clarification.

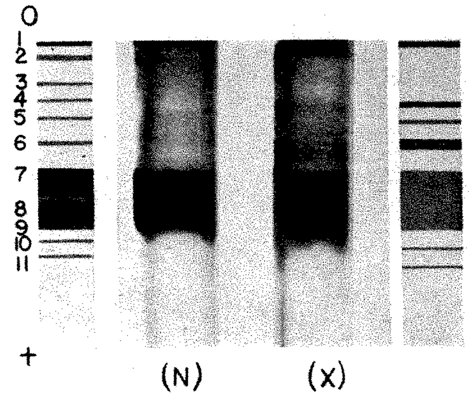
Brain homogenates and blood sera were centrifuged in a Servall model *RC*-2 refrigerated ultracentrifuge at 20,000*g* at 2° C for 60 min, following the method of Barron *et al.*[4]. The clear supernatant fractions of the brain homogenates were concentrated to about 40 per cent of their original volume at 3° C with 'Sephadex *G*-25' (Pharmacia) by the procedure of Flodin *et al.*[5], pipetted into clean tubes, and stored at 3° C prior to electrophoresis.

Electrophoretic separation of the samples was performed in polymerized acrylamide matrices consisting of a 12·5 per cent acrylamide lower gel and 3·3 per cent acrylamide spacer and sample gels, cast in soft glass tubes 64 mm long by 5 mm inside diameter, according to the technique described by Ornstein and Davis[6]. Eight replicate gel columns of both concentrated brain homogenate supernatant (100 µl.) and blood serum supernatant (10 µl.) were separated concurrently at a constant current setting (Beckman Duostat model *RD*-2) of 3 m.amp per tube (~ 120–155 V) for 80 min at 15° C using 0·05 M *tris*-glycine buffer, *p*H 8·3. Immediately following electrophoresis the gel-containing tubes were placed in ice water, and the gel plugs removed within 15 min for transfer to the appropriate substrate solution, selective inhibitor, or acetic acid/amido-Schwartz reagent.

Esterase substrates included α-naphthyl acetate, α-naphthyl butyrate, and 5-bromoindoxyl acetate (Sigma) in 0·2 M *tris*-maleate buffers, *p*H 6·0–7·5, prepared according to the methods of Allen and Hunter[7] and Barron *et al.*[4]. Fast blue *RR* (Sigma) was the diazo-coupling agent utilized. Esterase (including cathepsin) inhibition was performed with diisopropyl fluorophosphate (DFP) 10^{-6} M,



BRAIN TISSUE



BLOOD SERUM

Fig. 1. Protein patterns of rat brain tissue and blood serum from normal (*N*) and X-irradiated (*X*) animals. Major differences in brain tissue proteins appear at anodic bands *A* 2–4 and 6–10. Blood serum protein differences occur at anodic bands *A* 2, 3, 4, 6 and 10–11

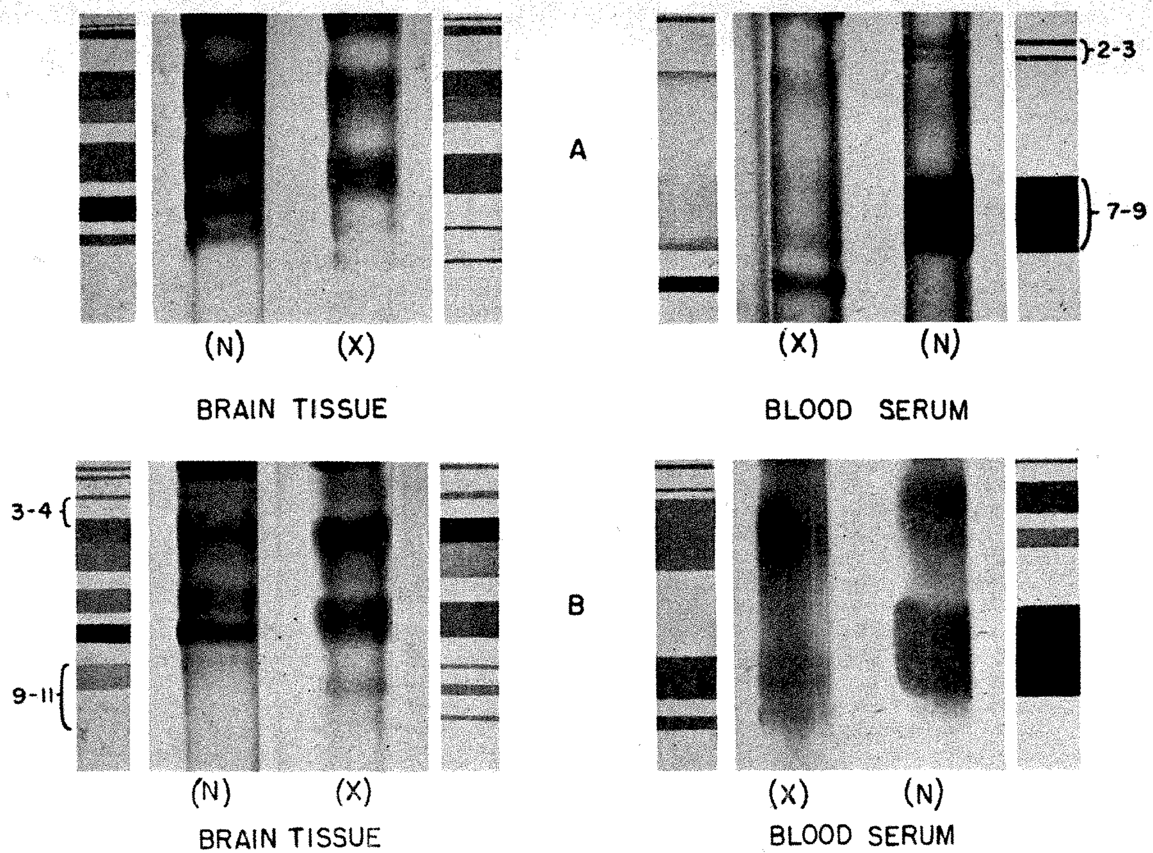


Fig. 2. Esterase patterns of rat brain tissue and blood serum from normal (*N*) and X-irradiated (*X*) animals. α-Naphthyl acetate (*A*) and α-naphthyl butyrate (*B*) substrates in 0·2 M *tris*-maleate buffers, *p*H 6·8. Major differences in brain tissue esterases at anodic band regions *A* 3–4 and 6–10. Blood serum differences in anodic band regions *A* 2–3 and 7–11

0·2 M *tris*-maleate buffers, *p*H 5·0–7·5, at 25° C for 2 h prior to transfer to the appropriate esterase substrate solutions. Incubation in the substrate solutions ranged from 2 to 16 h at 25° C. Protein staining in amido-Schwartz reagent was carried out for 16 h at 25° C, and electrophoretically de-stained in 10 per cent acetic acid at 8 m.amp for 90 min.

Figs. 1 and 2 show clear-cut differences in the protein and esterase patterns of the irradiated and control halves of the rat brains. The major differences in the protein patterns (Fig. 1), anodic bands *A* 2–4 and 6–10, correspond fairly closely to the different position and intensity of the esterases demonstrable with α-naphthyl acetate (*A*) which occur in those regions. This is brought out more clearly for the *A* 8–10 band region with α-naphthyl butyrate (*B*) as the substrate. 5-Bromoindoxyl acetate, the substrate utilized by Zeaman *et al.*[1] in conjunction with DFP to demonstrate Type-*C* cathepsins, did not reveal any noticeable differences in activity between irradiated and normal brain tissue, as only band regions *A* 3–5 (and possibly 11) showed any distinguishable reaction with this substrate.

DFP at 10^{-6} M markedly inhibited bands *A* 1, 4 and 6–7, but only partially blocked the activity of the other esterase bands. Thus, the differences in esterase activity produced by irradiation appear to be not only attributable to the Type-*C* cathepsins proposed by Zeaman *et al.*[1], but to other esterases as well. The proteolytic activity of these bands was tested with *N*-benzoyl-DL-arginine-β-naphthylamide (BANA) according to the method of Ravin[8], as modified by Barron *et al.*[4]. The results indicated a similar distribution as that demonstrated by the naphthol and indoxyl ester substrates with DFP, thereby confirming the proteolytic nature of some of these DFP-resistant esterases.

Blood serum protein and esterase patterns (Figs. 1 and 2) differ markedly between normal and irradiated animals. The major differences appear in anodic bands *A* 2, 3, 4, 6 and 7–11, with the albumin and pre-albumin regions (~*A* 7–11) exhibiting striking alterations from irradiation. Note that the esterase activity of the pre-albumin region is faint-to-absent in the blood from the normal animal, and quite distinct in the X-irradiated rat serum. However, the albumin region adjacent to it (bands *A* 7–9) shows just the converse esterase activity in these animals. This notable difference is brought out vividly by assay with both α-naphthyl acetate (*A*) and α-naphthyl butyrate (*B*). It is interesting that the amido-Schwartz protein stain appears to show a similar protein density in the albumin region of both sera, yet the esterase components of the irradiated serum were markedly inactivated. When α-naphthyl acetate was used as the esterase substrate bands *A* 2–3 were clearly distinguishable in the normal serum, but were almost totally absent in the irradiated serum electrophoretic pattern. 5-Bromoindoxyl acetate did not react with these bands (*A* 2–3), but did with bands *A* 7–9. Thus, although esterase bands *A* 2–3 coincide in some measure with esterase bands *A* 3–4 of the brain homogenates, they are most probably of a different constitution, at least so far as the nature of their esterolytic activities is concerned.

DFP greatly reduced the activities of all the esterase components of normal and irradiated sera except *A* 8, a possible cholinesterase I. BANA revealed significant proteolytic activity only in bands *A* 6–7.

The changes brought about in the esterases of brain cells and blood serum by cranial X-irradiation would therefore seem, on the basis of the differences in electrophoretic migration and substrate–inhibitor reactivity, to be largely indigenous to the respective systems. The most profound changes occurred in the blood, which is known to be more sensitive to the effects of X-rays than the central nervous system[3]. Several of the esterase components of the blood serum zymogram patterns were decidedly inactivated by irradiation, while the brain tissue zymogram patterns exhibited an apparent increase and/or decrease in the activity of certain esterolytic proteins These divergencies in the zymogram patterns may not only represent additions and/or deletions of enzymatically active molecules from the various cellular elements comprising the brain tissue, but also certain ancillary changes in their structural configurations and charge distributions as well Work is being carried out to characterize further those esterases which are effected by X-irradiation, and determine their role in the progression of functional changes brought about by irradiation of the central nervous system and its vital circulatory network

We thank Dr Roberts Rugh, Department of Radiological Research, for advice and assistance in the X-irradiation and other important phases of this work

PARTIAL AGONISTS IN THE CENTRAL NERVOUS SYSTEM

By GLENDA M. LAYCOCK and A. SHULMAN
Department of Physiology, University of Melbourne

THE concept of a drug possessing dual action, both agonist and antagonist, has been derived from studies in a variety of *in vitro* systems Such drugs have been called partial agonists, and hypotheses have been proposed to explain their action in terms of 'occupation' theory[1,2] and 'rate' theory[3] of drug action Although drugs showing both agonist and antagonist action in the central nervous system have been reported previously[4-8], no explanation has been offered for these observations

We wish to report the existence of substances with the properties of partial agonists among a series of β-substituted glutarimides and related drugs, the actions of which in mice range from convulsive and analeptic (agonist) to anticonvulsive and hypnotic (antagonist)[9-11] The following suggestions are based on quantitative titrations over a wide dose range with a series of structurally related and structurally unrelated hypnotics and analeptics in mice and on structure-action studies with β-substituted glutarimides and related drugs which will be reported fully elsewhere It is proposed that hypnotics and analeptics produce their opposed actions at common sites in the central nervous system[12-14] and that, in terms of 'rate' theory, convulsant and analeptic drugs are agonists with high k_2 (dissociation rate constant of drug-receptor complex), hypnotic and anticonvulsive drugs which antagonize convulsions induced by pentylenetetrazol are competitive antagonists with low k_2, and partial agonists have intermediate values of k_2 which may be closer to those of agonists or to those of competitive antagonists, 'occupation' theory can also be applied to explain the action of such drugs[15] It is considered that convulsive and analeptic drugs and likewise hypnotic and the foregoing anticonvulsive drugs differ primarily in their affinity for the common receptor surfaces

The glutarimide and related partial agonists (Tables 1 and 2) may for convenience be divided into two classes depending on whether their actions resemble more closely those of agonists or antagonists The first class of partial agonists, the k_2 values of which appear to lie closer to those of agonists, have lethal convulsive action and are analeptic to pentobarbitone, in higher doses they antagonize the maximum tonic extensor component of pentylenetetrazol or bemegride convulsion, provided that the mice are protected from the initial lethal convulsive action of the partial agonist Although they have no definite hypnotic action when given alone, in still higher doses they significantly increase the number and generally the sleeping time of mice given the HD_{50} dosage of pentobarbitone Mice which lose righting reflex may show associated signs of stimulation and on awakening a state of hyperexcitability and limb spasticity which may be followed later by mild convulsions These partial agonists are also analeptic to trimethadione and in higher doses synergize with its hypnotic action except in cases where death by respiratory depression intervenes

The second class of partial agonists, with values of k_2 presumably closer to those characteristic of antagonists, produce convulsions which, if not lethal, decrease in intensity to be followed by sedation and sometimes loss of righting reflex which is generally associated with stimulant action While the majority of such partial agonists are analeptic to trimethadione but not to pentobarbitone,

‡ New compound synthesized by Handley, G F, and Somers, T C (personal communication).

they are generally more powerful antagonists to the lethal convulsive action of pentylenetetrazol or bemegride and synergists of hypnosis induced by pentobarbitone or trimethadione

It may be seen (Tables 1 and 2) that the following series of very small changes in the components of the agonist bemegride (β-methyl-β-ethylglutarimide) gives rise to a number of partial agonists of distinct chemical types

(1) The introduction of a methylene group into the β-alkyl side-chain, for example, β-methyl-β-*n*-propylglutarimide and β,β-diethylglutarimide, (2) the introduction of a methyl group on to the α-carbon atom (α,β-dimethyl-β-ethylglutarimide), (3) the replacement of both oxygen atoms of the carbonyl groups by sulphur atoms (β-methyl-β-ethyldithioglutarimide), (4) the replacement of one or both carbonyl oxygen atoms by hydrogen atoms (4,4-methylethylpiperidone-2 and 4,4-methylethylpiperidine hydrochloride), (5) the replacement of the —CO—NH— grouping by the —CH_2—O— grouping (β-methyl-β-ethylvalerolactone), (6) the introduction of an ethyl, allyl, phenyl or phenethyl group on to the glutarimide ring nitrogen atom

These structural alterations presumably all increase the strength of the bond formed between the drug and receptor surface, since k_2 of a partial agonist is lower than that of an agonist, whereas certain small structural modifications of the hypnotic β-methyl-β-*n*-butylglutarimide appear to decrease the strength of the drug-receptor bond to produce partial agonists, for example, *N*-ethyl-β-methyl-β-*n*-butylglutarimide or the *N*-allyl analogue (7) and β-methyl-β-*iso*butylglutarimide (8) (Table 1) Types (1), (2), (3), (5) and (8) are partial agonists of the first class described, while (4), (6) and (7) belong to the second class, full experimental details and the possible mechanisms involved will be described elsewhere[15,16] It is of considerable interest that sodium diphenylhydantoin ('Dilantin'), which is highly effective in antagonizing convulsion induced by electroshock but not by pentylenetetrazol[17], shows many of the characteristics of a partial agonist of the second class

The foregoing observations permit the following conclusions

(*a*) The existence of drugs which are structurally closely related to both agonists and antagonists and which show both agonist and antagonist action supports the postulate that convulsion and hypnosis are initiated by these drugs at common receptor surfaces The progressive change within the homologous series of β,β-dialkylglutarimides (Table 1) from agonist (β-methyl-β-ethylglutarimide) to partial agonist (β-methyl-β-*n*-propylglutarimide) to antagonist (β-methyl-β-*n*-butylglutarimide) is analogous to that found among a variety of closely related homologues in *in vitro* systems[1-3,18,19]

In this context it is of marked importance that *N*-ethylation or *N*-allylation of the agonist bemegride and the closely related antagonist β-methyl-β-*n*-butylglutarimide gives rise, in both cases, to drugs with partial agonist action (Table 1) If hypnotic and convulsive action were taking place at separate sites, it would be very difficult to explain how the introduction of the same *N*-alkyl substituent could convert a convulsive drug to one which is able to act at both sites and likewise a hypnotic drug into one which can act at the convulsant as well as the hypnotic site However, if hypnotic and convulsive action both occur at the same site it might be expected that the *N*-ethyl or *N*-allyl substituent would decrease the exactness of fit to the receptor surface of a hypnotic drug, which most likely fits closely since k_2 is low, while increasing the capacity for binding of the smaller convulsant drug, thus enabling it to form a stronger bond with the receptor surface Thus the *N*-ethyl or *N*-allyl substituent by increasing k_2 of the hypnotic and decreasing k_2 of the convulsant could convert both to partial agonists

(*b*) Since the structural modifications which produce alteration in pharmacological action from agonist or antagonist to partial agonist are small, the associated changes in the value of k_2 would also be small; this might be anticipated from observations in rats and mice with analgesics and their antagonists[20] and has been demonstrated[3] for a homologous series of alkyltrimethylammonium cations on isolated guinea-pig ileum

(*c*) Since a small structural alteration at each position of the bemegride molecule leads to a change in pharmacological action from agonist to partial agonist, it would seem that the bemegride molecule as a whole, and presumably those of its closely related homologues and derivatives, must contribute to the strength of the drug-receptor bond and that the degree of steric and polar complementariness of the drug and receptor surface are most important in determining the resultant pharmacological response It may be predicted that, as in the case of β-substituents, a progressive change in action from agonist to partial agonist to antagonist will occur as substitution or modification of the α-carbon or nitrogen atoms or modification of the carbonyl groups of bemegride progressively increases the strength of the drug-receptor bond

(*d*) β-Substituted glutarimides are poorly ionized at physiological *p*H (refs 21 and 22) and presumably the type of bonds by which the drugs are bound to the receptor surface are van der Waals's forces, dipoles and hydrogen bonds Their pharmacological action and interaction with structurally related and structurally unrelated agonists and antagonists must therefore be a physical rather than a chemical process, a suggestion consistent with that proposed in many theories on the mode of action of central nervous system stimulant and depressant drugs[6,23] The variety of chemical types found among the partial agonists related to bemegride supports such a concept and suggests that the receptor surface lacks precise specificity in its requirement of drug structures to which it will respond, specificity is strict, however, with respect to the type of pharmacological response produced The increase in basicity associated with the conversion of the agonist bemegride to the partial agonists, 4,4-methylethylpiperidone-2 and 4,4-methylethylpiperidine hydrochloride suggests that the receptor surface has some cationic character

A hypothesis suggesting that β-substituted glutarimides are but one of a series of central nervous system stimulant and depressant drugs[4-8,20] which act and interact at common receptors in the central nervous system of mice, and probably of other animal species, will be reported elsewhere[15]

We thank the Directors of Nicholas Pty Ltd , Victoria, Australia, for supplying the drugs used in this investigation and for giving us access to the results of screening tests carried out in the Nicholas Institute for Medical and Veterinary Research, Victoria, during 1955–60 This work was supported by the National Health and Medical Research Council of Australia

RESISTANCE TO FINGER COOLING RELATED TO PHYSICAL FITNESS

By Dr CHARLES J EAGAN

Arctic Aeromedical Laboratory, Fort Wainwright, U S Air Force, Alaska

PREVIOUS investigations[1,2] in this laboratory showed that subjects maintained higher peripheral temperatures during standardized cold exposure after a 3-week regimen of physical training The authors concluded that higher levels of physical fitness were "alone responsible for the physiological differences manifested between the control and experimental periods"[1] These conclusions have been widely quoted although it has been inferred by Hammel[3] and others that a "metabolic acclimatization"[3] was the salient feature, higher extremity temperature might be an incidental consequence of a higher metabolic rate after the training regimen This explanation was compatible with the results of the first investigation[1] but not the second[2] In subsequent work at this laboratory it was casually noted that there seemed to be little or no correlation between level of physical fitness and resistance to cooling of the fingers The two experiments to be described substantiate this

(1) The investigation of which this experiment is part was made during May–July 1962 Some of the results are reported elsewhere[4]

Two groups of subjects were compared Physical results are given in Table 1 The five mountaineers had all attained high levels of physical fitness in the course of training for and making an ascent of Mount McKinley, Alaska They returned directly from the expedition to the Arctic Aeromedical Laboratory, where they lived for three days The controls were 19 U S Air Force personnel of the laboratory staff, all were of mainly sedentary habitus

At individual nadir		0 96 ± 0 50	0 95 ± 0 24	NS
Average over 10 min		3 36 ± 0 76	3 86 ± 0 33	NS
Tolerance factor (units)‡ (air at −22° C, 850 kcal/m²/h 'windchill')		253 ± 50	234 ± 60	NS

* Standard error

† Basal metabolic rate was measured on only five of the control subjects

‡ Tolerance factor (units) = duration of cooling (min) × average finger temperature (°C) during the exposure

The same treadmill test[5] for physical fitness was used as in the first investigations mentioned[1,2]. The mountaineers were each tested twice, but most of the controls only once The thermal and metabolic tests were done with the subjects in the basal state, having slept overnight at the laboratory Finger temperatures were measured using stranded No 30 copper-constantan thermocouples and a recording potentiometer The thermocouples were attached at standard sites on the distal digital volar pads Conditions of severe cooling were imposed on the fingers, first on the index fingers immersed 2 8 cm in stirred 0 0° C water for 10 min while the subject was prone in bed. Then he arose, dressed in his usual clothes plus a heavy parka, moved to an adjoining room and exposed the index and middle fingers of the left hand in a refrigerated box at a temperature of −22° C, 'windchill' was approximately 850 kcal/m²/h This test was for 30 min, but was stopped if either finger supercooled below −5° C or superficial freezing was observed

A 'tolerance factor' equal to the duration of exposure in minutes multiplied by the average finger temperature during exposure was computed for each subject.

Table 1 shows the results. The responses to severe cooling of the fingers were essentially the same in the highly fit mountaineers and the sedentary controls

(2) The investigation of which this experiment is part was made during April–May 1963 The main part of the work was a comparison of thermal responses to cooling of the extremities in the following groups 6 Alaskan Eskimos, 6 Alaskan Indians and 6 Navajo Indians, all of whom had attended the Chemawa Indian School in Oregon for the nine months before the investigation, 6 University of Oregon students who were 'controls' All groups were matched for age and body-size The results reported here are of comparisons between equal numbers of the subjects separated on the basis of level of physical fitness The 'highly fit' group consisted of the 3 Eskimos, 3 Alaskan Indians, 3 Navajos and 3 controls who had the highest physical fitness scores[5] The 'less-fit' group consisted of the other 12 subjects The treadmill test[5] was made twice on each subject Fat percentages were estimated from skinfold measurements[6]

Resistance to cooling of the extremities was assessed using mild and severe cooling of the fingers (in 0° C air

Table 2 PHYSICAL DATA AND THERMAL RESPONSES ON SUBJECTS OF DIFFERENT LEVELS OF PHYSICAL FITNESS

‡ Finger excess temperature = finger temperature minus calorimeter temperature

and 0° C water, respectively) and moderate cooling of the whole hand involving rise-in-temperature calorimetry (starting at 4 5° C) Duration of cooling for each test is listed in Table 2 Finger temperatures were measured as already described Test conditions were similar to those for the first experiment Subjects slept overnight at the laboratory Finger cooling (both in air and in water) was carried out with the subject supine and in the basal state. Hand calorimetry was performed in the afternoon after lunch Cooling was not begun in any of the tests until finger temperatures were at least 35° C

Table 2 shows the results There is a marked similarity in the means for all factors except for physical fitness Most of the criteria for resistance to cooling had been shown to be efficient measures from comparisons of the Alaskan versus Navajo and control groups where highly significant differences were found (unpublished results) But level of physical fitness seems unrelated to the thermal responses to cooling of the extremities

The results of these two experiments seem conclusive When the resistance to cooling of the extremities is investigated under standardized conditions, there are no differences that can be attributed to level of physical fitness How, then, may these results be related to the opposite conclusion from previous work[1,2] where differences were found in the responses of subjects after training ? It may be relevant that habituation to a test procedure can improve resistance to cooling of the fingers[4] Perhaps more salient is the work of Osiba[7], who showed that a high protein intake combined with high physical activity resulted in a sustained increase in basal metabolic rate. Subjects on a regimen of strenuous physical training[1,2] who were allowed food *ad libitum* could be expected to eat more protein Thus, Osiba's conditions for a sustained elevation in basal metabolic rate would be satisfied In fact, Adams and Heberling[1,2] did find a higher resting metabolism for their subjects after training in the first investigation[1] but not in the second[2]

It is concluded that the results of Adams and Heberling are probably being wrongly interpreted when improved resistance to extremity cooling is ascribed to improved physical fitness There is probably no causal relationship The validity of the important finding of these workers that many of the indices for cold acclimatization can be explained on the basis of increased physical activity is not being questioned But the importance of change in level of physical fitness *per se* is indeed questionable

I thank the test subjects for their co-operation and especially for their forbearance during tests which caused severe cold pain I also thank the Bureau of Indian Affairs, the Superintendent and staff of Chemawa Indian School, Oregon, and the staff of the Department of Health, Recreation and Physical Education of the University of Oregon, especially Prof P O Sigerseth, for co-operation; Staff Sergeant Paul Felts, U S Air Force, for assistance; Dr Eugene Evonuk and Dr F A Milan for their interest and assistance

CHANGES IN THE RATE OF METABOLISM FOLLOWING ADMINISTRATION OF ETHANOL IN THE MOUSE

By PROF F W. KINARD

Department of Physiology, Medical College of South Carolina, Charleston

THE mouse, with its ease in handling, convenience in housing, and relatively low cost, has been increasingly used by us in investigations of ethanol metabolism Of some concern is the finding of Marshall and Owens[1] that although the rate of oxidation is relatively constant 1 h after administration of ethanol, the rate may be twice as fast during the initial 60 min On the contrary, Nelson *et al* [2] found no statistically significant difference between the rates determined at the end of either 1 or 3 h Marshall's hypothesis was confirmed in general by Forney *et al* [3], but the early accelerated rate was found to occur during the first 30 min following injection of the alcohol This problem in metabolism, viewed somewhat differently by three groups, is of sufficient practical and theoretical importance to deserve further investigation If the mouse does not metabolize ethanol at a constant rate, the maximal rate of metabolism cannot be obtained by rate determinations during randomly selected intervals, for example, between the second and third hours after administration

The recent development of improved methods of homogenizing and the availability of accurate hypodermic syringes led us to attempt to develop a standard technique of determining the rate of ethanol metabolism in mice The various steps in the technique were examined critically The intervals of study were selected to include the important ½- and 1-h periods plus a longer period of 4 h

Mice, Carworth Farms white females, weighing 19–25 g, were given free access to Purina checkers and water until the beginning of the experiment The experimental animal was weighed, injected intraperitoneally with ethanol, 4 g/kg/body-weight, using a stock 20 per cent w/v solution of ethanol in physiological saline A Hamilton syringe, calibrated in 0 01 ml, was used routinely At the end of the experimental period, either 0 5, 1 or 4 h, the mouse was killed by breaking its neck The entire carcass was divided four or five times with scissors and homogenized for 5 min in sufficient water to give a 1 5 homogenate The homogenation was carried out in a semi-micro blending assembly, surrounded by ice water, and adapted to the motor drive of the gallon-size Waring blender Following homogenation, an aliquot of the homogenate, approximately 5 ml, was pipetted into a tared stoppered distilling flask The flask was re-weighed to determine the weight of homogenate added and to permit calculation of the weight of tissue utilized The reagents, that is, sodium sulphate, sodium tungstate and sulphuric acid, were added and the ethanol content determined by the distillation method of Aull *et al* [4]

The adequacy of the methods used was determined by the following experiments

(1) *Chemical method* Repeated analyses of the stock solution of ethanol were made, using calibrated pipettes and burettes instead of the Hamilton syringe This experiment was expected to show the degree of reproducibility in the chemical method

(2) *Homogenation, water* Ethanol, 0 5 ml of stock solution, was introduced by syringe into water, 25 0 g and homogenized for 5 min The resulting solution was treated as though it were tissue of an experimental animal and the ethanol concentration determined This experiment was intended to reveal losses during homogenation and variations occurring when measurements were made with the syringe

(3) *Zero hour mouse* An animal was killed, weighed, injected intraperitoneally by syringe with stock solution of ethanol, 0 5 ml /25 g body-weight The procedure from this point onwards was identical with that described for the experimental animals This experiment had a two-fold purpose, namely (*a*) to indicate whether pooling of the dose of ethanol in the peritoneal cavity, which occurs in the dead mouse without circulation, would result in complete dispersion of ethanol during homogenation, and whether the tissues would be sufficiently comminuted to permit representative sampling, (*b*) to give the exact concentration of ethanol in the mouse, as determined by analysis following the various procedures necessary to prepare the tissue for analysis The mean value of these determinations should indicate the concentration of ethanol considered to be present in an experimental animal, immediately following injection, and before metabolic activity had begun

The results of these investigations are summarized in Table 1 In the method described, as noted in homogenation, water and stock solution, respectively, the combined basic mechanical operations and the chemical method introduce the smallest errors The larger error, in the zero hour series, stems from the difficulty in completely homogenizing the various components of the carcass, thereby preventing representative sampling The duration of homogenation can be prolonged to secure better comminution, but this is accompanied by increased heating of the homogenizer and increased opportunity for evaporation It is now suspected that the 5-min period selected is not optimum The results, in the remaining three groups where experimental animals are used, appear to be within the range expected in this type of experiment

When the results in Table 1 are used to calculate the rates of ethanol metabolism found in Table 2, the standard deviations of the mean, as well as the range, increase noticeably Obviously, any variation is compounded since the rate of metabolism is calculated by the following steps (½ h) 398 1 − 375 2 = 22 9 × 2 × 10 = 458, (1 h) 398 1 − 342 5 = 55 6 × 10 = 556, (4 h) 398 1 − 159 4 = $\frac{238\ 7 \times 10}{4} = 594$ These results are not identical with those in Table 2 since the tabulated results represent the mean of the individual experiments The mathematical processes, therefore, play a part in producing the wide range in the results, particularly in the ½-h series

Table 1 ETHANOL IN TISSUE OR SOLUTION
(mg ethanol/100 g tissue, or solution)

	No of expt	Mean, *S D*	Range
Stock solution	12	399 6 ± 1 6	396–401
Homog , water	12	399 8 ± 2 9	392–402
Zero h mice	12	398 1 ± 11 5	378–409
½-h mice	12	375 2 ± 8 7	361–386
1-h mice	11	342 5 ± 7 3	332–353
4-h mice	11	159 4 ± 27 4	118–194

Table 2 RATE OF ETHANOL METABOLISM
(mg ethanol/kg/h)

	No of mice	Mean, *S D*	Range
½-h	12	455 0 ± 173 3	240–740
1 h	11	555 5 ± 73 1	450–660
4 h	11	595 5 ± 68 3	510–700

The decision to utilize the mean concentration of ethanol determined in the zero hour groups as the actual concentration of ethanol present in each individual experimental mouse at the start of the experiment was made in order to obviate the various errors introduced by the mechanical and chemical operations Instead of this approach, one can consider the concentration of the stock solution, as determined by analysis, to represent the actual concentration of ethanol administered Using the latter method, the mean values for the rate of ethanol metabolism, expressed as mg ethanol/kg/h, as indicated as follows, are approximately 7 per cent higher than those determined through utilization of the zero hour series: ½-h series 488, 1-h series 571, 4-h series 600

The mean calculated rate of oxidation, by Marshall and Owens[1], was 536 mg/kg/h This is in approximate agreement with my presently reported rate of 555 and well below the previously reported[2] rate of 625 in the 1-h group The rates given by Marshall and Owens for the direct determinations, 1,322 for ½ h, 1,123 for 1 h and 691 for 3 h, differ markedly, in the first two instances, from my present results of 455 for ½ h and 555 5 for 1 h, and less drastically, in the last instance, from the 595 5 I found in the 4-h group If the mice examined by Marshall and Owens oxidized ethanol during the first ½ h at the rate of 1,322 mg/kg/h, this would mean that only 462 mg/kg were oxidized during the second ½ h (1,123 − 661 = 462) During the 3-h period, oxidization of 2,073 mg/kg (3 × 691), with 661 mg/kg being oxidized during the initial ½ h, indicates that 282 mg/kg of ethanol were oxidized during each ½ h following the initial ½ h ($2{,}073 - 661 = \frac{1{,}412}{5} = 282$) Therefore, Marshall and Owens found a declining rate of oxidation, for example, 661 during the initial ½ h, 462 during the second, and a mean rate of 282 per ½ h over the remaining four periods of ½ h. By similar calculations, the rates of oxidation in our investigations were found to be 227 mg/kg during the initial ½ h, 328 during the second ½ h, and a mean rate of 308 per ½ h over the remaining six periods of ½ h each

In view of the fact that the lowest rate in our investigations was obtained in the ½-h experiments and the highest in the 4-h series, an explanation has been sought A possible explanation is that during the early phase of each experiment, insufficient alcohol had been absorbed to bring the oxidative reaction to its maximum rate, hence an overall slower rate was exhibited in the shorter experimental periods In the longer experiments, although we did not investigate this specific phenomenon, one would expect more alcohol to be lost by excretory routes, mainly through lungs and kidneys, with the result that such losses would sum with the loss due to oxidation to give an erroneously high rate of metabolism The loss of ethanol by excretion is probably not great in these experiments of relatively short duration, for of the total amount of alcohol administered, according to Lester and Greenberg[5], 1–5 per cent may appear in the expired air Contrariwise, Lundquist *et al*[6] consider that the loss of ethanol through the lungs is very considerable in the rat The best explanation appears to be that the shorter duration experiments indicate a rate which is not representative of the mean rate in a 3- or 4-h experiment In the longer experiments, this period of sub-optimal rate of oxidation occupies a proportionately smaller portion of the total time, thus leading to higher rates in the longer experiments

Statistical analysis of our results indicates that there is no significant difference between the rates during ½, 1 or 4 h . The disturbingly large standard deviations, especially in the ½-h series, indicate such wide ranges of individual values that this conclusion must be expected If one wishes to determine the rate of ethanol metabolism during the peak rate, the duration of the experiment must be sufficiently long to minimize the interval required for absorption As the period of investigation is prolonged, the quantity of ethanol lost by excretory routes will be increased Obviously, other factors can be controlled, such as magnitude of the dose administered and consequently the level of concentration in the blood In these experiments, the dose of 4 g/kg was chosen in order to work at the same concentration levels which had been used earlier It appears that the duration of such experiments can be limited to 3 or 4 h, but shorter periods of investigation yield rates which have not yet reached maximum values

AGGREGATION OF CULTURED MAMMALIAN CELLS

By PROF MERWIN MOSKOWITZ

Department of Biological Sciences, Purdue University, Lafayette, Indiana

THE histotypic aggregation of dissociated embryonic cells has been extensively studied in recent years[1] This aggregation is observed with cells from young embryos, and the ability of the cells to aggregate declines and eventually disappears as the age of the embryo increases or if the cells are cultured[2]. I have observed that under appropriate cultural conditions cells of established strains form aggregates that resemble those obtained with dissociated embryonic cells Following this observation, an investigation of the factors affecting the aggregations of cells of established strains was undertaken and the initial findings are presented here The investigations carried out so far indicate that these factors are not susceptible to simple definition Different strains of cells vary markedly in their ability to aggregate, and different cultural conditions seem to be required for the aggregation of strains that have been observed to aggregate

The term 'aggregate' is used here to denote a group of cells tightly packed together into an oblong or spherical structure usually having a continuous layer of peripheral cells forming a relatively smooth surface (Figs 1 and 2) A group of cells loosely held together with a rough edge, appearing as if individual cells randomly attached to each other, is termed a 'clump' (Fig 3) These two types of groupings of cells were observed and they are distinguished inasmuch as there appear to be qualitative differences in their behaviour All the cells of a clump appear to attach and spread out when it is allowed to settle to a glass surface, and the cells of a clump are readily dissociated by trypsin An aggregate of cells acts like a tissue fragment under these conditions, it retains its structure on a glass surface and cells grow out from it as with a tissue explant, and it takes a relatively long while for trypsin to dissociate the cells in the aggregate

The fibroblastic cells used were clone cultures derived from the *Mox*[3] and *L* strains, and strains *WISH*, Girardi's Heart, *Hep* 2, and Salk Monkey Heart comprised the epithelial cells The cells were grown in nine volumes of Eagle's medium[4], modified by adding four times the vitamin concentration and three times the amino-acid concentration, plus one volume of horse (unless otherwise specified) serum or the dialysate of a tissue extract The latter protein-free medium is similar to one previously described[5], except that dialysates of saline extracts of porcine pancreas tissue were utilized instead of serum dialysates.

The cell inoculum was prepared by scraping off the surface growth from the culture vessel with a rubber policeman and dispersing the cells with a capillary pipette Only single cells were present in suspensions of fibroblastic cells, and single cells plus occasional clumps of two or three cells were present in suspensions of the epithelial strains Cells were agitated in tubes containing 1 ml of medium on a roller drum apparatus at 60 r p m or in 25-ml Erlenmeyer flasks containing 3 ml of medium on a rotary shaker at 70 r p m The cultures were incubated at 37° for 7 days without a change of medium

All the strains of cells used grew as monolayers in stationary cultures in serum supplemented medium, in the protein-free medium the *Mox* and *L* strains appear the same as in serum, the *WISH* and *Hep* 2 strains have a tendency to grow in patches, and the Girardi's Heart and Monkey Heart strains did not become attached to the glass but formed aggregates

Initial investigations by rotating cells on the roller-drum apparatus were carried out with the *Mox* strain In serum-supplemented medium the cells remained discrete and some clumps formed, in protein-free medium aggregates formed on the third day which increased in size during the remaining four days of incubation A number of clone cultures of the *Mox* and *L* strains were then tested on the roller drum in serum-supplemented and protein-free medium One culture aggregated only in protein-free medium, one culture aggregated only in serum-containing medium, two cultures aggregated in both media, and two cultures did not aggregate The *WISH* and Girardi's Heart of the epithelial strains aggregated on the roller drum to a slight extent and only in serum-supplemented medium

Further experiments were carried out on the rotary shaker The behaviour of the fibroblastic strains was similar to that observed on the roller drum, and, although all the epithelial strains aggregated, there was a variation in aggregative behaviour with different media.

The effect of variation in media on aggregation was tested by determining the aggregation of the epithelial cells in media supplemented with different sera and in protein-free medium. The results of such an experiment are given in Table 1. In addition to the variation in aggregation in a given medium, even the immediate past history of the strains appears to be a factor in their aggregatability. For example, the aggregation properties of cells grown for four passages in medium supplemented with agamma horse serum or fœtal calf serum were different when tested in various media than cells grown in horse serum-supplemented medium.

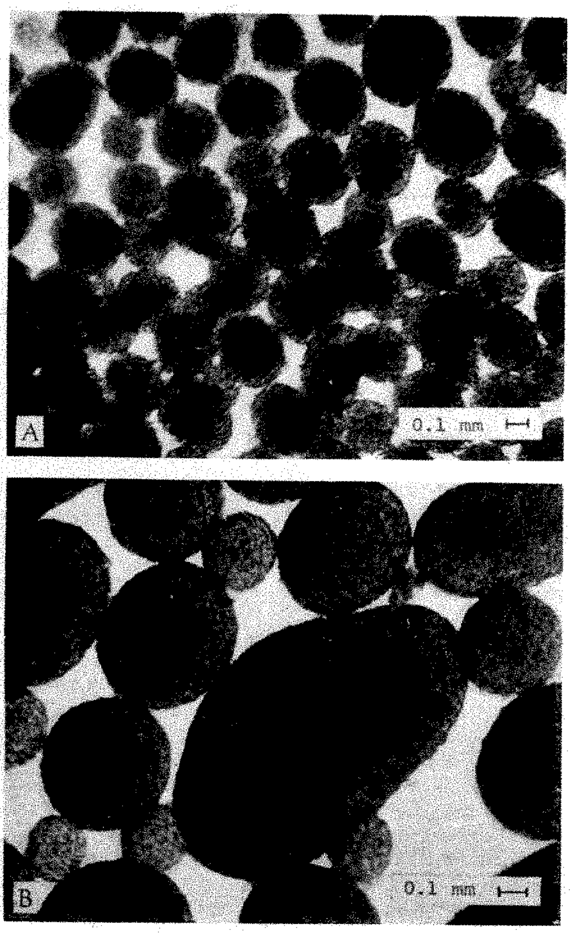

Fig. 1. Aggregates: *A*, strain *WISH*; *B*, *L* strain

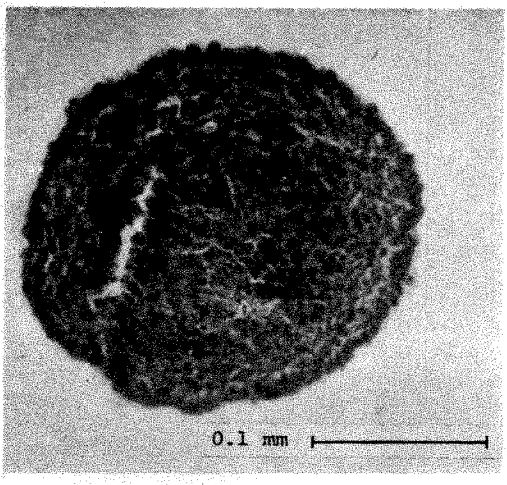

Fig. 2. Section through aggregate. *L* strain (safranin and fast green)

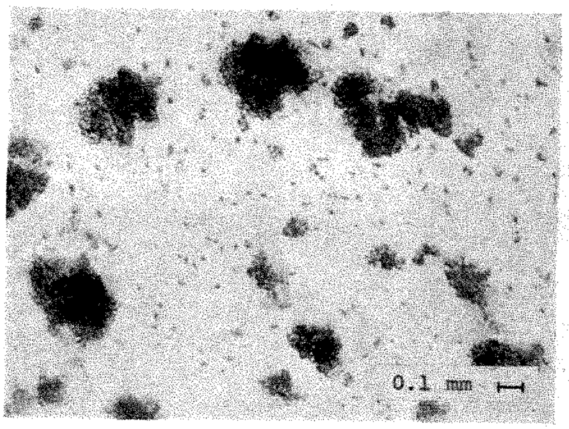

Fig. 3. Clumps. Strain *WISH*

The effect of the inoculum size was tested by determining the aggregation of the epithelial strains in media containing horse, agamma horse or fœtal calf serum with inocula of 5 × 10^5, 2 × 10^6, and 6 × 10^6 cells per flask. In flasks where aggregation occurred, it occurred earliest and there were larger aggregates with the smallest inoculum, the aggregates were slightly smaller with 2 × 10^6 inoculum, and extremely small aggregates formed late in the experiment with 6 × 10^6 inoculum. With Monkey Heart cells in fœtal calf serum, aggregates formed with the smallest inoculum and not with the larger inocula. An inoculum of 1 × 10^6 per flask was finally standardized in further experiments.

Inasmuch as the number of cells in suspension is a factor in the aggregation of the cells, the attachment of a portion of the cells to the glass surface with some of the media and conditions of rotation utilized affects the aggregation of the cells. In order to prevent the attachment of the cells to the glass, flasks were coated with silicone. Occasionally a thick layer of cells which had attached to the glass would break off and would be observed as a ribbon-like clump of cells. On the roller drum, aggregates would sometimes be seen among the cells attached to the glass. Sheets of cells were observed floating on the surface in a few fibroblastic cultures on the rotary shaker. Such sheets of cells were noted previously[6] and were quite distinct from the aggregates and clumps reported here.

In a few instances single cells were observed during the entire period of agitation. In the usual pattern of events, however, clumps formed within a few hours after agitation was initiated, and they usually increased in size during the course of the agitation period. They varied in size from a few cells to large clumps up to 0·5 mm in diameter. The density of clumps varied with different strains and media. In some instances aggregation occurred within 24 h, but aggregates usually did not form for two or three days. It appeared that cells comprising the clumps underwent some change which caused the clumps to acquire the property of an aggregate. The aggregates were often quite uniform in size (Fig. 1), but with some strains and media they varied in size from 0·2 to 1 mm.

Aggregation is not merely the association of cells which results when they are placed under conditions which do

Table 1. AGGREGATION OF CELLS IN DIFFERENT MEDIA

Cell strain	Medium supplement: Horse serum	Agamma horse serum	Fœtal calf serum	Tissue extract dialysate
Monkey heart	*A**	*C*	*C*	*C*
WISH	*A*	*C*	*A*	*C*
Girardi heart	*A*	*A*	*C*	*C*
Hep 2	*S*	*A*	*A*	*A*

* *A*, aggregate; *C*, clump; *S*, single cells.

not permit their attachment to the glass surface. Under such conditions cells usually remain single or form small clumps. The following observations suggest that aggregation occurred because of a change in the cells induced by the conditions under which they were cultured: the clumps, which formed in a matter of hours, did not invariably become aggregates; it took from 3 to 7 days for aggregates to form; and aggregates have properties qualitatively different from clumps. This change is undoubtedly related to a change in their surface properties, and it is apparent that subtle differences in the cultural conditions under which these cells are grown affect these surface properties. Specific substances, such as enzymes or other proteins, may be produced in association with the changes in the cells that cause them to aggregate. The possibility that such substances are produced will be investigated inasmuch as any new substance produced by the cells, or a marked increase in the production of one of their normal constituents, may provide information regarding the nature of the changes occurring in the cells which cause them to aggregate.

Although most established strains of cells have lost many of the properties of the cells of the tissue from which they were derived, the information to produce such properties is probably retained. The ability to join with other cells to form a tissue is one of these lost properties, and it may be speculated that the conditions which induce established strains to aggregate are those which permitted the expression of this bit of information. Further expression of the information within the cell may result in the formation of structures with a greater degree of organization. No specific histotypic structural features have thus far been observed, but we have on occasion noted what appeared to be organized regions in the aggregates. Investigations are in progress to determine if established strains of cells and mixtures of such different cell strains can form aggregates with structures resembling those of the tissue from which they were derived.

Leighton has observed the formation of relatively small aggregates when established cell lines were grown within a cellulose sponge[7]. He directs attention to the fact that most clinical carcinomas appear as aggregates or nests of cells, and suggests that factors intrinsic to the formation of aggregates are involved in the spread of the cancer. The specific conditions that cause the formation of aggregates in agitated cultures may thus be related to the development of neoplastic potentialities by the cells. This possibility will be explored.

I thank Dr. Grace Amborski for her assistance. This work was supported by a grant from the U.S. National Institutes of Health (*GM* 07733).

ON THE UNIVALENT FRAGMENTS OF HUMAN 7 S GAMMA-GLOBULIN

By D. STOLINSKY and PROF. H. FUDENBERG

Department of Medicine, University of California School of Medicine, San Francisco 22

HYDROLYSIS of 7 *S* rabbit antibody by papain yields three 3·5 *S* fractions separable by chromatography on carboxymethyl cellulose[1,2]. Two of these fractions, designated I and II by Porter, resemble each other in possessing univalent antibody activity[3–5] and in antigenic characteristics and molecular weight. Fraction III lacks antibody activity. Palmer, Mandy and Nisonoff[6] recently demonstrated that fractions I and II are derived from different parent molecules rather than being fragments of the same molecule (as originally thought), and showed that the relative amounts of fractions I and II vary reciprocally, depending on the chromatographic behaviour of the parent γ-globulin. Confirmatory evidence for this concept was recently furnished by Stelos *et al.*, using another method[7].

Various methods of fractionating the papain digest of human 7 *S* γ-globulin have been developed[8–12]. Only the method of Franklin, however, is comparable with that of Porter in producing three fractions. These fractions, designated *A*, *C* and *B*, correspond to fractions I, II and III, respectively, of rabbit γ-globulin[9]. (A small fourth fraction, designated *D* and probably representing intact 7 *S* material, is sometimes observed.) According to Franklin's results, the relative amounts of *A* and *C* in digests of pooled human Cohn fraction II varied, depending on the chromatographic and electrophoretic behaviour of the parent γ-globulin, whereas the proportion of *B* was relatively constant[9]. The basic fraction was rich in the positively charged fragment *C* while the more rapidly migrating fraction contained primarily the more negatively charged fragment *A*. However, no conclusions were made on the basis of this observation on whether or not *A* and *C* are derived from the same parent molecule. The apparent heterogeneity of Cohn fraction II in this respect might merely reflect its origin from γ-globulins of different individuals. The work recorded here attempted to clarify this point by sub-fractionating γ-globulin derived from single individuals on the basis of charge.

Sera from normal subjects, four patients with multiple myeloma, and three with an 'incomplete' anti-Rh antibody were the source of γ-globulin. In brief, the 7 *S* γ-globulins were isolated by diethylaminoethyl cellulose (DEAE) chromatography and separated into 'acidic' and 'basic' components by carboxymethyl cellulose chromatography or starch-block electrophoresis. These 7 *S* sub-fractions were then digested with papain and the resultant 3·5 *S* products were separated by sequential chromatography on carboxymethyl cellulose and DEAE columns. Experiments were also performed with fragments *A* and *C* of the 'incomplete' anti-Rh antibodies to evaluate their serological attributes.

Normal γ-globulin was prepared from 50-ml. samples of serum from two normal donors (P. S., Gm(a^{+}), Inv(a^{+}), and J. D., Gm(a^{-}), Inv(a^{-})) by elution from a 4 × 40 cm DEAE column[13] with 0·01 M phosphate buffer, *p*H 8·0. This yielded pure 7 *S* γ-globulin as shown by immunoelectrophoresis[14]. A 250-ml. sample of each protein was further separated into four sub-fractions on a 2 cm × 30 cm carboxymethyl cellulose column, using stepwise elution as follows: buffer 1, 0·005 M phosphate, *p*H 6·6; buffer 2, 0·01 M phosphate, *p*H 6·6; buffer 3, 0·025 M phosphate, *p*H 6·9; buffer 4, 0·05 M phosphate, *p*H 7·1, plus 0·04 M sodium chloride. In a further experiment, normal γ-globulin was applied to a carboxymethyl cellulose column with 0·025 M phosphate, *p*H 6·9, plus 0·025 M sodium chloride to elute the 'acidic' and 'intermediate' portions; 0·05 M phosphate, *p*H 7·6, plus 0·5 M sodium chloride (buffer 5) was then used to elute the most 'basic' portion. The 7 *S* γ-paraproteins of two patients with multiple myeloma were prepared similarly by elution from a DEAE column. The γ-cryoglobulins of two other myeloma patients were isolated and purified by repeated cold precipitation and washing. All the globulin preparations were concentrated to 15 ml. by dialysis against polyethylene glycol and then against phosphate-buffered saline, *p*H 7.0. The solutions were made 0.01 M in cysteine and 0.002 M in disodium ethylenediamine tetraacetate, mercuripapain (Worthington Biochemicals) was then added in the amount of 1 per cent of the protein by weight. Digestion was allowed to proceed at 37° C for 16 h and was then stopped by dialysis against 100 ml. of 0.01 M phosphate buffer, *p*H 7.6, in the cold. The amount of dialysable material formed was determined by a modified Folin technique[15]. The digests were fractionated in the cold by the two-step chromatographic method of Franklin[9] (carboxymethyl cellulose columns at *p*H 7.6, followed by DEAE columns at *p*H 8.0). The same batch of ion exchanger and the same conditions of flow rate and buffer were used for each run. The amount of protein in each fraction was determined by optical density at 280 mμ. γ-Globulin possessing incomplete anti-D (anti-Rh_0) activity was isolated in the same manner as the γ-globulin devoid of demonstrable antibody activity for this specific antigen. Anti-Rh activity was assayed by standard methods[16]. In all negative serological tests, serial dilutions were used to ensure that a prozone did not exist.

Table 1 shows the relative amounts of protein in the fractions (expressed as percentage of the parent protein) obtained from digests of normal γ-globulin (J. D.), its chromatographic sub-fractions, and the myeloma proteins. As shown, the most 'acidic' sub-fraction of normal γ-globulin (that is, the sub-fraction most easily eluted from the carboxymethyl cellulose column, and hence presumably possessing the lowest isoelectric point) yielded *A* but no *C*. The most 'basic' sub-fraction (that is, the sub-fraction eluted last) yielded mainly *C* and little *A*. The intermediate sub-fractions yielded intermediate ratios of *A* to *C*. Similar results were obtained with chromatographic sub-fractions of another normal γ-globulin (P. S.). The myeloma proteins resembled the artificially produced sub-fractions of normal γ-globulin in yielding markedly unequal amounts of *A* and *C*. (The property of cold precipitation was lost by the cryoglobulins after papain digestion, and was not present in any of the fractions or various mixtures thereof.) In confirmatory experiments, 'fast' and 'slow' sub-fractions of the two normal γ-globulins (P. S. and J. D.) were isolated by starch-block zone electrophoresis[17]. The relative amounts of *A* and *C* fragments obtained from papain digests of 'fast' and 'slow' sub-fractions isolated by starch-block electrophoresis were similar to those obtained from the 'acidic' and 'basic' chromatographic sub-fractions, respectively. Agar diffusion examination of the isolated *A*, *B* and *C* fragments of the 'acidic' portion obtained by chromatographic fractionation gave bands of identity with the comparable fragments obtained by isolation of the 'fast' γ-globulin from starch-block electrophoresis. The same was true of the papain fragments of the 'basic' (chromatographic) and 'slow' (starch-block) fractions of the 7 *S* γ-globulin.

Table 2 shows the representative results obtained with one (Ri) of three incomplete anti-Rh antibodies. The parent γ-globulin possessed incomplete anti-Rh activity as measured by antiglobulin test and by its ability to agglutinate *D*-positive erythrocytes treated with ficin or suspended in 30 per cent albumin. No agglutination was observed in saline. The papain digest of the Ri γ-globulin and its *A* and *C* fractions retained anti-Rh activity as measured by the antiglobulin test with rabbit anti-serum to the *A* and *C* fragments, but showed no detectable activity against red cells pre-treated with proteolytic enzymes (ficin, trypsin and papain) or suspended in albumin. The *B* fraction was inactive by all three methods. These results are in accord with those obtained by Fudenberg, Mandy and Nisonoff[18] with rabbit 7 *S* hæmagglutinins. (The localization of anti-globulin activity of incomplete anti-Rh antibody to the *A* and *C* fragments was previously observed by Deutsch *et al.*[19].) In a further experiment, the intact anti-Rh γ-globulin (Ri) was sub-fractionated chromatographically into 'acidic' and 'basic' portions. The papain digest of the 'acidic' portion yielded mainly fraction *A* and little *C*, whereas the 'basic' portion yielded the reverse. As before, anti-Rh activity was confined to *A* and *C*. As a control on the chromatographic method, a part of the 'acidic' anti-Rh γ-globulin (*A*/*C* ratio 59:1) was mixed with a ten-fold excess of the 7 *S* γ-globulin (not sub-fractionated) of 'normal' sera lacking anti-Rh activity. The mixture of 'acidic' anti-Rh and of normal γ-globulin was then digested with papain. Although comparable amounts of *A* and *C* were obtained, the anti-Rh activity was limited to fraction *A*. When the 'basic' fraction of anti-Rh γ-globulin was mixed with normal γ-globulin, the anti-Rh activity was confined almost exclusively to papain fraction *C* of the resultant mixture.

These observations indicate that the differences in the net charge of γ-globulin molecules in the serum of a single individual are reflected in the varying proportions of *A* to *C*. The relative amounts of *A* and *C* depend on the charge of the parent γ-globulin. The fact that only these two fractions, *A* and *C*, are obtained from a parent γ-globulin consisting of molecules having a spectrum of charges is probably attributable to the chromatographic method[6,20]. Since molecular weight data[8,9,11] indicate that each 7 *S* γ-globulin molecule consists of two sub-units of the *A*–*C* type and one of the *B* type, it seems likely that some γ-globulin molecules contain either two *A* or two *C* sub-units, that is, two identical univalent fragments. Present results, however, are not sufficient to support the hypothesis that this holds true for all γ-globulin molecules. The fact that the electrophoretically homogeneous myeloma proteins (Table 1) yielded either almost two parts of *A* and almost no *C*, or two parts of *C* and almost no *A* (relative to one part of *B*), is in keeping with this hypothesis. (The trace amounts of *A* in myelomas 1 and 4 and of *C* in myelomas 2 and 3 presumably are due to small amounts of normal (non-myeloma) γ-globulin in the myeloma sera.)

In parallel experiments, the 3.5 *S* fragments of two 7 *S* γ-globulins containing incomplete anti-Rh activity were prepared by sequential treatment with pepsin and a reducing agent[21], their behaviour when tested by anti-

Table 2. TITRES* OF ANTI-RH ANTIBODY (RI) AND ITS PAPAIN DIGEST FRACTIONS BY VARIOUS TECHNIQUES

γ-Globulin preparation	Method Antiglobulin	Ficin†	Albumin	Saline
Intact (7 *S*)	1:10,000	1:10,000	1:200	—
Papain digest	1:1,250	—	—	—
Fraction *A*	1:1,000	—	—	—
Fraction *B*	—	—	—	—
Fraction *C*	1:1,000	—	—	—

* End-point of final dilution causing detectable reaction. Initial concentration of protein solutions was 10 mg/100 ml.

† Similar results were obtained when cells were treated with trypsin or papain.

globulin, ficin and albumin methods was identical with that of similar fragments prepared with papain The 3 5 *S* fragments of a human 7 *S* anti-*A* isoagglutinin also failed to agglutinate the appropriate erythrocytes, whether or not the latter were treated with enzymes or suspended in a high protein medium However, combination of these fragments with the homologous antigens did occur, as shown by the occurrence of agglutination when an antiserum specific for the 3 5 *S* fragments was added (In a few experiments, the digest of the antibody appeared to retain a slight ability to agglutinate erythrocytes treated with enzymes or suspended in a high protein medium, but in each case this was found to be caused by the persistence of small amounts (1–3 per cent) of intact 7 *S* material, removable by gel-filtration on 'Sephadex *G*-200') Similar results have been obtained previously with rabbit bivalent 7 *S* agglutinating antibodies[18]

The results obtained with the papain digest of the incomplete anti-Rh antibodies merit further comment, in that they provide some basis for speculation on the relationship of the structure of such antibodies to their 'incomplete' character The serological behaviour of the papain digest and its *A* and *C* fractions is what would be expected of truly univalent antibodies, that is, combination with antigen (as detected by the antiglobulin technique), but inability to cause agglutination of appropriate erythrocytes, even when the latter are pre-treated with ficin or suspended in a high protein medium The parent 'incomplete' antibody, which reacts by all three methods, presumably is bivalent[18] The means by which enzyme treatment of erythrocytes or the presence of a high protein medium enables 'incomplete' blood group antibodies to produce agglutination remain to be clarified The mechanisms responsible for the serological behaviour of 'incomplete' antibodies are at present being investigated in studies with univalent fragments of chromatographically sub-fractionated human γ-globulin

REPRODUCTION IN A FREE-LIVING POPULATION OF DOMESTIC RABBITS, *ORYCTOLAGUS CUNICULUS* (L.), ON A SUB-ANTARCTIC ISLAND

By E. SHIPP

AND
K. KEITH, R L. HUGHES and K. MYERS
CSIRO Division of Wildlife Research, Canberra

SINCE 1948 the Australian National Antarctic Research Expedition (ANARE) has maintained a station at Macquarie Island (54° 30′ S , 158° 57′ E) Situated in latitude mid-way between New Zealand and Antarctica, the Island represents the southern limit of rabbit distribution in the Australasian region

The climate is bleak, temperatures varying little from the mean of 40 0° F The mean difference between the hottest and coldest months is 6 0° F and the mean diurnal range is only 5 7° F

Precipitation is evenly distributed throughout the entire year (Table 1) and the average relative humidity is extremely high (92 per cent) Wind gusts exceeding 60 m p h are frequent in every month The average annual sunshine is 1 8 h/day and is concentrated during the period of maximum plant growth (October–March) when a mean monthly maximum of 3 h/day may be reached[1] Even under these bleak conditions the domestic rabbit has continued to thrive since its original introduction by sealers about 1880 The relatively narrow variations in so many climatic factors provide the ecologist with a unique opportunity to investigate those factors which determine the duration of breeding

Observations were made in two separate years by two of us (1950–51 (E S) and 1956 (K K)) while members of ANARE parties at Macquarie Island The number of animals examined each month appears in brackets in Table 1 The large animals were selected in shooting, and the obviously immature ones were ignored in the analysis of the results Body-weight, number of embryos, stage of pregnancy (determined from gross inspection of the uterine horns) and number of corpora lutea were recorded soon after animals were shot Testes were fixed in 10 per cent formalin and were later cleaned and weighed Frozen sections of testes were cut at 20μ and stained with hæmatoxylin and eosin

The combined reproductive data for the two separate years 1950–51 and 1956 are shown in Fig 1

It can be seen that the proportion of females either pregnant or lactating increased from a few per cent in July to 100 per cent in December and thereafter decreased until the cessation of breeding in May. Both testis weight and spermatogenetic activity (determined by the percentage of testes containing either sperm or spermatids) showed a similar trend, although maximum reproductive activity in the males was reached earlier and persisted longer Two other trends were apparent in females Pre-natal reproductive wastage, based on corpora lutea counts of pregnant females, was highest in the earlier months of breeding, being 50, 72 and 80 per cent in September, November and December compared with 15 per cent in February and 24 per cent in March and

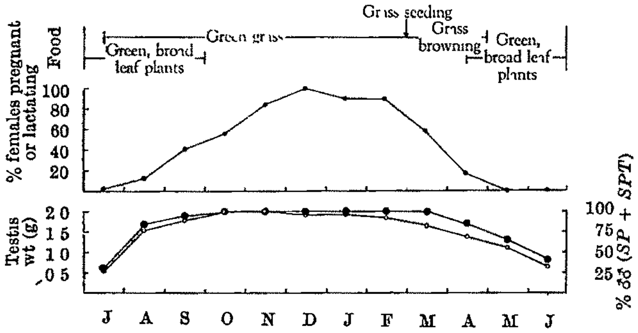

Fig 1 The breeding season of rabbits on Macquarie Island Upper graph ●, percentage females pregnant or lactating, lower graph ○, testis weight in grams, ●, percentage males in which the testis was producing either sperm or spermatids (or both), *SP*, sperm, *SPT*, spermatids

April The number of eggs shed at each ovulation showed a gradual increase in all but the last month of breeding, being 6, 7, 7 4, 7 8, 6 8 in September, December, February, March and April respectively

A prominent feature of reproduction is the relatively long breeding season (July–May) The short annual anœstrus (May–July) corresponds with the season of no plant growth when the preferred pasture species (grasses) are not available (Fig 1). Anœstrus is accompanied by variable loss of weight (Table 1), which is probably caused by fluctuations in both the availability and nutritional value of food

The importance of nutrition is underlined by comparisons between reproductive data (August 1950–April 1951) from two adjacent but dissimilar areas, one with luxuriant plant growth, the other over-grazed and relatively bare, to the extent that rabbits were digging for roots A very small creek, which rabbits were not seen to cross, separated these areas sharply

It can be seen from Fig 2 that females occupying the well-vegetated habitat apparently have a longer and more effectual breeding season than those living in the denuded area In the vegetated area the height of breeding, as judged by the percentage of females pregnant, was reached about one month earlier and continued at a level some 6–20 per cent above that found in females taken from the over-grazed area. The results also suggest that females on the better pasture maintain maximal breeding for about one month longer

The picture in the males is essentially similar Males from the vegetated area almost always have a higher mean

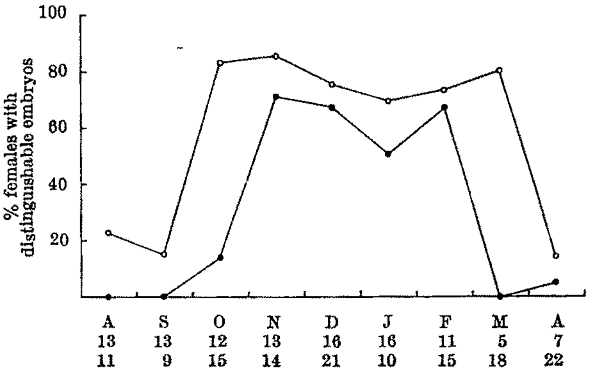

Fig 2 Effect of habitat difference on breeding, 1950–51 season, Macquarie Island
Upper curve ○, well-vegetated area, lower curve ●, denuded area Pregnancy was ascertained from gross inspection of the uterine horns The figures which appear below the letters denoting the month refer to the sample size The upper and lower figures correspond to the upper and lower curves, respectively

testis weight (Table 2) The annual enlargement of testis and accompanying weight increase occurs two months earlier and probably persists at least a month longer than that found in males living in the bare region The testis tubules of all but one male from the better pasture contained either sperm or spermatids during the period August–April (Table 2) In contrast, males from the denuded area during the same period exhibited reduced spermatogenic activity during August, September and particularly April In addition, low levels are shown in Fig 1 for June and July when males were taken only from the bare area

These differences in reproductive performance, and in weight (Table 2), between the rabbits of the two areas may be primarily related to nutritional values of the pastures, though some effect may be ascribed to increased cover and variations in microclimate

The two factors which appear to be correlated with the initiation and maintenance of breeding are day length and season of plant growth Day length *per se* appears to be of little importance, as wild rabbit populations throughout their entire range in the Australian region have overlapping breeding seasons (pregnancy and lactation) which cover every month of the year[2-4] However, a large portion of the Australian range is of a Mediterranean-type climate where summer anœstrus is the rule, and this is in marked contrast with the Macquarie Island breeding pattern A common factor pertinent to breeding in

Mean body-weight males and females (g)	*a*	2,153	2,096	2,068	1,954	2,124	2,040	2,090	2,068	2,068
	b	1,816	1,812	1,700	1,812	1,898	1,898	2,011	1,954	1,954

Group *a*, animals from well-vegetated areas, group *b*, animals from denuded area almost all regions, including Macquarie Island, is nutrition In all areas where adequate studies have been made, breeding is initiated by the commencement of the growing season—the shooting of green grass or equivalent preferred plant species being a potent stimulator (Fig 1) Reproduction falls off and eventually ceases in the latter portion of the growing season when pastures deteriorate The importance of nutrition in domestic rabbit reproduction was recognized by Hammond and Marshall[5]

Preliminary observations have been made on natural populations of wild rabbits in sub-tropical Queensland, Australia Although the season of plant growth is here coincident with spring and summer rains, the proportion of pregnant and lactating adult females is reduced during the hottest months suggesting that temperature and not nutrition may be limiting[4]

We thank the many members of the ANARE who helped with the field work on the Island

DETERRENT EFFECT OF INSECTICIDES ON MALARIA VECTORS

THE effect of residual insecticides on malaria vectors is commonly assessed in the laboratory by using treated panels or containers lined with paper impregnated with the insecticide under examination, with which anophelines from laboratory cultures of known age and feeding conditions are brought into contact The effect of the toxicant investigated is usually judged by knock-down counts and by immediate and 24-h delayed mortality figures For the assessment in the field, the investigator relies largely on the numbers of vector species caught in treated houses resting or biting, and, since the pioneer work of Muirhead-Thomson[1] in Africa, on the results obtained in experimental huts fitted with exit traps, in which it is possible to count the number of mosquitoes dead on the floor and the number found in the exit trap dead or alive and, by holding the latter for a 24-h period, to estimate the delayed mortality Feeding conditions and ovary development of the females caught are usually noted, and to this has been added in recent years the determination of their physiological age by one of the methods described by Detinova[2]

These comparatively simple techniques have shown that the action of the residual insecticides against a winged insect like an anopheline mosquito, free to enter human dwellings in search of food or shelter, is more complex than would perhaps have been suspected Kennedy[3] was probably the first to observe in the laboratory that DDT had an irritant effect on mosquitoes, an observation that was confirmed in the field by Muirhead-Thomson[1], Davidson[4] and many others, but the implications of the irritant effect of this insecticide on the transmission of malaria are not yet completely understood A repellent effect of DDT on house-haunting anophelines was noticed by Gebert and was confirmed later by Muirhead-Thomson[5], Downs and Bordas[6] and others DDT, it appeared, prevented anophelines from entering treated houses, and that it was not due to the irritation produced by this insecticide was shown when other chlorinated hydrocarbons with non-irritant properties, like BHC and dieldrin, also prevented anophelines from entering treated houses The importance of this action of residual insecticides has perhaps not been fully appreciated in the past, but recent observations in Africa indicate that it must have great operational significance

In the course of a successful malaria eradication pilot project in the district of Kigezi in Uganda, experimental huts with mud walls and thatched roofs were used, fitted with exit traps of the type described by Muirhead-Thomson[1] and Davidson[4] Each hut was baited with two men, and it was found that the one treated with 2 g DDT (75 per cent w d p) per m^2—the dosage applied in the area—caught, during the nine months it was in operation, only 30 5 per cent of the number of *Anopheles gambiae*—the local vector—that were captured in an identical unsprayed control hut[7] A clear-cut finding like this, it was considered, deserved further investigation, and, since the success of the campaign in Kigezi had reduced the population of *A gambiae* to practically nil after one year of spraying, it was decided to build a new series of huts in another part of Uganda where DDT or other residual insecticides had not been used in public health campaigns This was done in the district of Masaka, and there it was found that DDT in the form of 75 per cent w d p and at the dosage of 2 g per m^2, and dieldrin in a 50 per cent w d p formulation and at the dosage of 0 8 g/m^2, greatly reduced the number of *A funestus* and *A gambiae*—the two vectors in the area—entering sprayed huts Since in Kigezi our experimental huts, and indeed all the local huts in the area, had been sprayed not only indoors, as is the common practice, but also on the outside 'ingress surfaces' with which a mosquito will probably have been in contact when gaining access to a hut, it was decided to have some of the new experimental huts sprayed inside only and in others to have the insecticide applied to the inside surfaces as well as to the 'ingress surfaces' on the outside These were the door and door frame of the hut (they had no windows other than that to which was fitted the exit trap) and the portion of the eaves and upper part of the walls close to the approximately 0 5 m -1 m opening between the roof and walls through which mosquitoes entered

The reduction produced by DDT and dieldrin on *A funestus* in a seven-month period of observation is summarized in Table 1.

Table 1

	A funestus caught in window trap and floor captures		Per cent reductions in relation to the number caught in control hut	
Hut No	Females	Males	Females	Males
3 (control)	2,692	1,780	—	—
1 (DDT inside only)	534	334	80 2	81 2
4 (DDT inside and 'ingress surfaces')	299	203	88 9	88 6
2 (dieldrin inside only)	528	379	80 4	78 7
5 (dieldrin inside and 'ingress surfaces')	573	380	78 7	78 7

The greatest reduction observed was in hut No 4, where the irritant effect of the DDT applied to the outside surfaces may have contributed to preventing mosquitoes gaining access to the hut Altogether, DDT and dieldrin produced a reduction of 82 1 per cent in females and 81 8 per cent in males of *A funestus* There was also a marked reduction in the numbers of *A gambiae* caught in this experiment, but the numbers in this case were too small to warrant analysis Of great interest was the finding that mosquitoes of the genus *Mansonia*—practically all *Mansonia* (*Mansonioides*) *uniformis*—were not reduced in numbers by either DDT or dieldrin whether applied to indoor as well as outdoor 'ingress surfaces' or to indoor surfaces only There was in fact a slight increase of 9 per cent in the treated huts when compared with the control, unsprayed hut, and this, it should be noted, was observed in a particularly large sample 43,595 individuals, practically all females

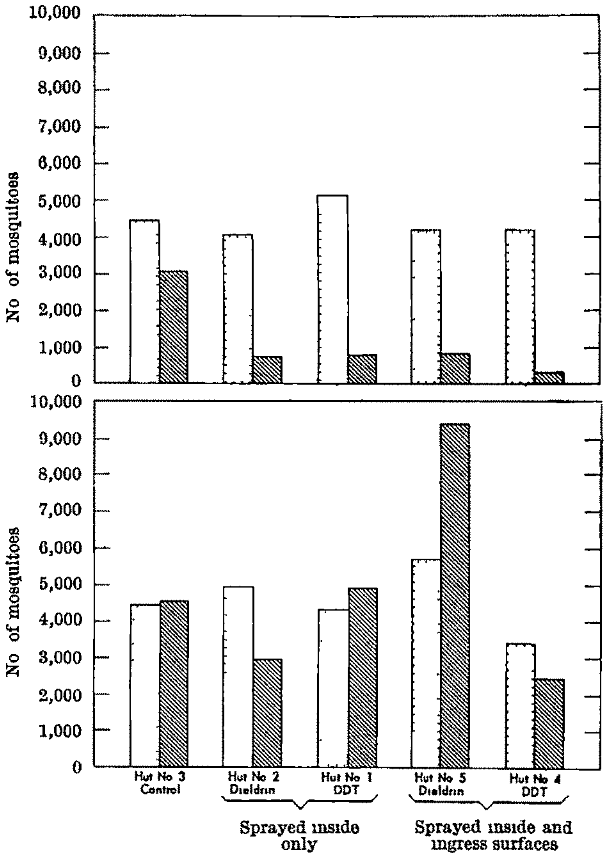

Fig. 1. Effect of DDT and dieldrin on female anophelines (above) and culicines (below) entering experimental huts. 'Before-spraying' (stippled) adjusted to equal time as 'after spraying' (hatched)

The very different effect of DDT and dieldrin on the anophelines and culicines in this experiment can also be appreciated by comparing in each individual hut the results before spraying with the results obtained after application of the insecticides. This has been done graphically in Fig. 1, where the period 'before spraying' has been adjusted to equal time as 'after spraying'.

Another series of observations made in Masaka, comparing the effect of DDT and dieldrin in metal-roofed and thatch-roofed huts, confirmed the phenomenon of reduced entry in anophelines. There was an overall reduction of 89·9 per cent in females and 96·4 per cent in males of *A. funestus* in the treated huts. A sufficient number of *A. gambiae* females were caught this time to show a reduction of 71·4 per cent. As in the previous experiment, *Mansonia* was not reduced in numbers in the treated huts, but showed, on the contrary, a slight increase of 12·5 per cent.

A full account of these observations will be published elsewhere, but it may be worth emphasizing here the importance of the phenomenon of reduced entry when assessing the effect of residual insecticides in anopheline mosquitoes. That the reduction was not an artefact in our results is clear from the finding of *Mansonia* in the same or slightly larger numbers in the treated huts, and also by the work carried out by other investigators like Wharton, Wilkinson[8] and Kuhlow[9], proving that a reduced catch in a treated hut was due in fact to a reduced entry and not to increased and unaccountable exit.

The reduced entry appears, therefore, as a very important factor when considering the overall action of residual insecticides, since a reduced entry means in fact a reduced contact between man and vector. Mortality figures, feeding conditions, physiological age of the mosquitoes captured, will not give a complete picture without a comparison of the numbers caught in treated and untreated huts, or those caught before and after treatment in the same hut.

If the importance of the reduced entry seems clear, the cause or causes of the phenomenon still remain uncertain. That irritation is not the main cause is proved by the fact that a reduced entry has been observed with non-irritant insecticides, such as dieldrin and BHC. That the presence of the insecticides is felt before contact with the deposits inside treated houses also seems clear. The effect then must be felt at a distance, and this must be due either to vapour released from the insecticide deposits or to particles drifting in the air in the vicinity of treated houses. Wilkinson[8] suggested that a reduced catch might be due to the masking of the attractive human odour by the smell of the insecticide, but this would leave unexplained the fact that engorged females are prevented from entering treated dwellings in search of a resting-place. We believe, therefore, that a cause or causes of a more general nature must be at work and that the use of the term 'repellency' either in the sense of contact repellency or of repellency at a distance, would not be adequate. We propose instead the use of the term 'deterrency' or 'deterrent effect' to embrace all possible causes that may prevent mosquitoes from gaining access to houses treated with residual insecticides.

THIS Institute assesses the toxicities of new insecticidal compounds to mosquitoes entering experimental huts. Because toxicity of the insecticide is greatly influenced by the time that mosquitoes spend resting in houses, our work has developed into a very specialized subject requiring a detailed knowledge of feeding and resting habits of the species of mosquito under assessment[1-3]. Our techniques have become more elaborate to assess concurrently the toxic effects of an insecticide and its effects on the behaviour of hut-entering mosquitoes. The chief remaining source of error in our routine assessments is that we have no measure of the proportion of hut-entering mosquitoes that leave through the eaves, or of the survival of these mosquitoes after egress. We have therefore investigated eave-egress in two ways by means of specially constructed huts.

(1) *By surrounding an experimental hut with a cage of mosquito netting.* A simple experimental hut, with a window-trap, was surrounded by a cage of mosquito netting, the sides of which were furled up to allow mosquitoes to enter the hut and unfurled to ground-level to trap mosquitoes leaving the eaves. The species examined were *A. gambiae* and *M. uniformis* which were collected by (1) hand-catches indoors; (2) a window trap in the east wall, (3) hand-catches outdoors within the cage. It was possible to examine the behaviour of unfed and fed mosquitoes, but not of gravid mosquitoes, because collections were made daily. Overall egress throughout the night was determined by combining the results of three periods, examined separately: dusk (5 p.m.–8 p.m.), darkness (8 p.m.–5.30 a.m.) and dawn (5.30 a.m.–7.30 a.m.).

The results in Table 1 are for forty collections. They show that nearly all unfed *A. gambiae* and *M. uniformis* left the experimental hut by dawn, with one-third of the total egress of *A. gambiae*, compared with 97 per cent of *M. uniformis*, leaving by the eaves.

Table 1 SHOWING THE EGRESS OF *A gambiae* AND *M uniformis* INTO A WINDOW-TRAP AND THROUGH THE EAVES OF AN UNTREATED EXPERIMENTAL HUT, IN THE MAGUGU AREA OF TANGANYIKA

	Unfed			Fed		
	Resting indoors	Egress by window	Egress by eaves	Resting indoors	Egress by window	Egress by eaves
A gambiae						
No	4	148	78	2,772	422	361
Per cent	2	64	34	78	12	10
M uniformis						
No	20	25	1,498	211	126	840
Per cent	1	2	97	18	10	72

Table 2 SHOWING THE NUMBERS OF *A gambiae* INDOORS (RESTING + DEAD ON FLOOR), IN WINDOW-TRAPS AND IN EAVE-TRAPS OF EXPERIMENTAL HUTS IN THE TAVETA AREA OF KENYA

Month	Untreated hut			Hut with dichlorvos in dibutyl phthalate			Hut with dichlorvos only		
	Indoors	Egress by window	Egress by eaves	Indoors	Egress by window	Egress by eaves	Indoors	Egress by window	Egress by eaves
1	807	999	142	1,263	338	292	961	302	182
2	704	811	64	438	139	163	747	590	116
3	631	265	42	601	299	165	919	648	124
4	470	259	62	831	547	149	654	630	108
5	290	158	57	690	373	106	357	272	54

The proportion of recently fed *A gambiae* in the window-trap was similar to that found in similar types of untreated experimental huts in Kenya[4], with about equal numbers of the recently fed *A gambiae* leaving by eaves and window-trap

The behaviour of *M uniformis* was quite different from that of *A gambiae* 72 per cent of recently fed *M uniformis* left by the eaves compared with 10 per cent of *A gambiae* This finding indicates that the present type of experimental hut, used for insecticide-assessment[5], would be unsuitable for assessing insecticides against *M uniformis* and other species with similar habits

(2) *By experimental huts fitted with eave-traps* The investigations were made in three wooden portable huts 8 ft. × 8 ft. and with walls $5\frac{1}{2}$ ft high Each hut was fitted with eight egress traps situated between the top of the walls and the roof, which was thatched but completely lined with ivory-faced fibreboard Each egress-trap extended 2 ft along the top of a wall and was V-shaped, the mouth being fitted with mosquito-netting to form a broad inset funnel with a mouth half an inch wide Light entered each trap from outside through a broad slit at the bottom, screened with wire mosquito-gauze Mosquito entry was through eight apertures, each 2 ft long, situated between shutters on the top of the walls and the roof, and alternating with the egress-traps The shutters were sited in relation to the roof to form V-shaped ingress-traps The ingress apertures were 1 in wide in these studies and were screened from mosquitoes inside the hut by narrow strips of cloth placed 3 in. in front of the shutters Provision was made for fitting window-traps in each wall. and the huts were made ant-proof by a method successfully used at Magugu[5] The work recorded here involved all eave-traps and one window-trap placed in the east wall

Investigations were made in an untreated hut and another containing a dichlorvos dispenser (Ciba VIII) that contained the insecticide in solution with dibutyl phthalate The third hut also had a dichlorvos dispenser (Ciba IX) which contained only technical dichlorvos. Mosquitoes resting in the huts were counted *in situ* in addition to observations required to determine overall mortalities[3], so that egress could be related to toxicity of the insecticide

Table 2 shows details of the egress of *A gambiae* into window-traps and eave-traps over a period of five months, and Table 3 shows that the proportion of the total egress that occurred through the eaves increased with overall mortality, as had previously been suspected[3] This latter finding indicates that the present type of experimental hut, used for routine insecticide assessment, is not entirely suitable for assessing irritant or repellent insecticides against *A gambiae* due to loss in efficiency of the window-trap when the insecticide is repellent

Table 3 SHOWING THAT THE PROPORTION OF THE TOTAL EGRESS OF *A gambiae* THAT LEFT BY THE EAVES VARIED DIRECTLY WITH OVERALL MORTALITIES TO DICHLORVOS

Month	Untreated hut		Hut with dichlorvos in dibutyl phthalate		Hut with dichlorvos only	
	Overall mortality (%)	Total egress by eaves (%)	Overall mortality (%)	Total egress by eaves (%)	Overall mortality (%)	Total egress by eaves (%)
1	2	12	85	46	80	38
2	10	7	86	54	32	16
3	11	14	34	36	19	16
4	16	19	24	21	27	15
5	8	27	11	22	11	17

Experimental huts fitted with veranda traps as well as window-traps might be better

The results in Table 3 confirm as yet unpublished findings from experimental huts at Magugu that it is the dichlorvos itself that affects the behaviour of *A gambiae* and not the plasticizer as was first suspected[3]

Finally, the details of the eave-egress of *A gambiae* and *M uniformis*, described here, show that the observations of Zulueta and Cullen—although striking—do not constitute proof that the malaria vectors were greatly deterred from entering treated huts The reduced numbers of *A funestus* and *A gambiae* that they observed may equally be explained by the insecticides irritating many of them to leave by the eaves An increase in numbers of *M uniformis* is in fact what would be expected in an insecticide-treated experimental hut with only a window-trap as normally most of them leave the hut by the eaves the same night as they enter it, toxic effects of the insecticide could reduce the numbers leaving the hut but irritant or repellent properties could not appreciably increase the number leaving

I thank Mr R E Rapley for designing and building the portable trap-huts at Taveta

GAS YIELDS FROM ELECTRON-IRRADIATED COTTON CELLULOSE

By DR F. L DALTON, M. R HOULTON and J A SYKES

Radiation Branch, Isotope Research Division, Wantage Research Laboratory, U K Atomic Energy Authority

MEASUREMENTS by several workers have shown that the principal gaseous products produced when cellulose is irradiated in vacuum or in an inert atmosphere are hydrogen, carbon monoxide and carbon dioxide[1-3] In all cases irradiations have been carried out in sealed tubes at a limited number of high radiation doses in the range 10^7–10^8 rads Such experiments allow the build-up of considerable pressures of reactant gases above the cellulose, and hence introduce the possibility of back reaction In some cases, the outgassing procedure has not been sufficiently rigorous to remove all oxygen from the cellulose, so that some oxidative breakdown may have

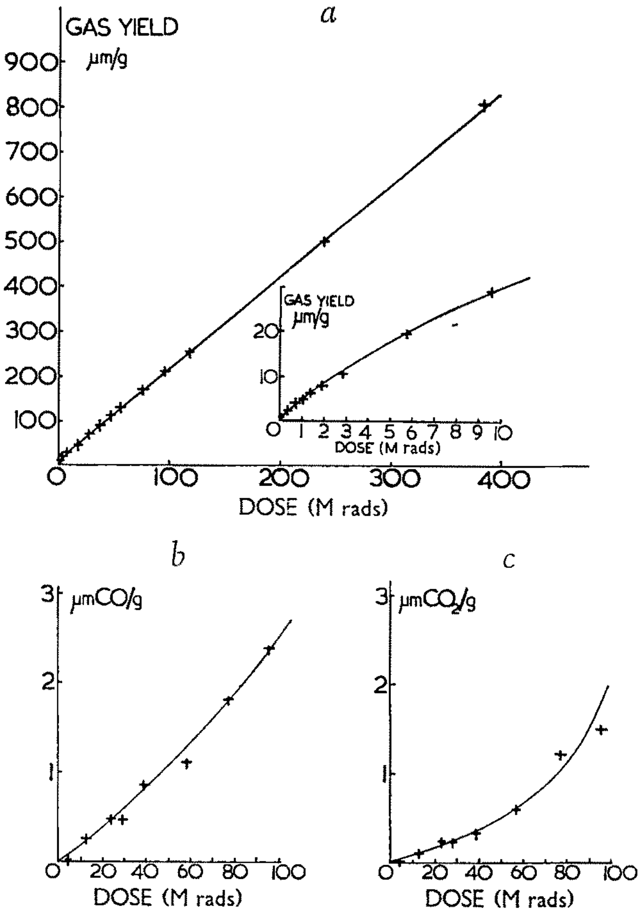

Fig. 1. (a) Total gas yield as a function of radiation dose (inset expands the scale at low doses); (b) carbon monoxide yield as a function of radiation dose; (c) carbon dioxide yield as a function of radiation dose. In all cases the dose rate was 1·30±0·02 Mrads/min

occurred. No systematic study of the G value of products as a function of dose has been reported.

The purpose of this article is to show that the G value of hydrogen, the principal gaseous product, is dependent on total dose and that the reaction products depend critically on the efficiency of the outgassing of the cellulose.

The cellulose used was a 'middling' American cotton which was received as a gift from the Shirley Institute at Manchester, where it had been purified by boiling in 1 per cent caustic soda solution containing 0·15 per cent castor oil soap for 3 h at 35 lb./in.^{2} excess pressure, washing with hot water, treating with cold 0·1 normal hydrochloric acid, washing with cold water and then re-boiling at 35 lb./in.^{2} in 1 per cent caustic soda without soap. After this it was washed as before and dried.

Samples of 0·1–2 g in weight were outgassed on a conventional high vacuum apparatus at 60° C overnight, the pressure being below 10^{-5} mm mercury. It was shown that further pumping under these conditions for a period of one week did not affect the results obtained. The cellulose, contained in a small tube attached to a bulb of sufficient size to prevent the pressure of product gases rising above 1 mm mercury, was then sealed off and irradiated at ambient temperature by means of a 4-MeV Metropolitan Vickers linear accelerator, the dose rate being 1·30±0·02 Mrads/min. Radiation heating was kept below 20° C at the centre of the cellulose by playing compressed air over the reaction vessel. After irradiation, the amount of gas produced was measured by means of a Saunders–Taylor apparatus[4] and its composition afterwards determined by mass spectrometry.

In view of the possibility of small quantities of atmospheric nitrogen contributing to the carbon monoxide peak, carbon monoxide was also determined by gas chromatography. These latter results confirm the mass spectrometry data and will not be discussed further. To remove gas from the cellulose completely, the irradiated material was held at 40° C overnight before admission to the Saunders–Taylor apparatus. This produced no change in the gas yield at doses above 1½ Mrads, but eliminated the retention of small but significant quantities of hydrogen in the cellulose at very low doses.

The results obtained are shown in Tables 1 and 2, while Fig. 1 shows yield curves for hydrogen, carbon monoxide and carbon dioxide. It is clear that the gas is almost entirely hydrogen, a result which is in conflict with the conclusion of other workers. Fig. 2 shows a plot of G value versus dose for total gas (≏ hydrogen), and it can be seen that the G value rises from near 2 at high doses to around 6 at 0·1 Mrads. Both carbon monoxide and carbon dioxide are produced at an increasing rate as the total dose increases. This behaviour is typical of secondary products. The initial G values are 0·02 and 0·008 respectively. From Table 2 it can be seen that a material of mass 34, which may well be hydrogen peroxide, is also produced but in very low yield with a G of about 0·001.

In view of the much lower rate of production of carbon monoxide and carbon dioxide obtained in this work than

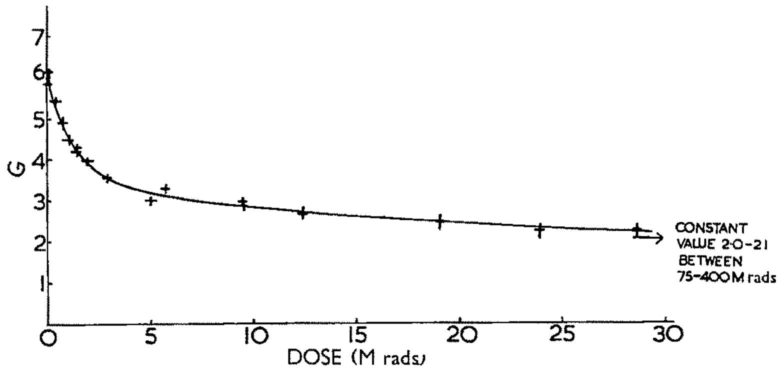

Fig. 2. $G_{\text{total gas}}$ ($=G_{H_2}$ to within experimental limits) as a function of radiation dose

in earlier studies, a check was made on the effect of outgassing. It was found that if 5 g of cellulose were packed into a tube of about 15-ml capacity, evacuated to a pressure of 0·002 mm mercury at room temperature and sealed off, irradiation to a dose of 47·8 Mrads gave a gas which was 82 per cent hydrogen, 5 per cent carbon monoxide and 13 per cent carbon dioxide. This compares with an interpolated analysis of 98·6 per cent hydrogen, 0·96 per cent carbon monoxide and 0·41 per cent carbon dioxide by our usual technique. From this experiment it would appear that unless the outgassing of the cellulose is carried out rigorously a considerable amount of carbon monoxide and carbon dioxide may be formed by oxidative processes, and this may well explain the discrepancy between our results and those of earlier workers. There is also some indication that if the pressure of product gas is allowed to build up above the sample, carbon monoxide and carbon dioxide yields are affected somewhat, but this has not yet been investigated thoroughly.

The change in *G* value with dose is of considerable interest and could arise from several causes, three of the most likely of which are outlined here.

(1) The existence of a small number of hydrolytically weak links in cellulose has been debated for many years, such links, if also weak in radiolysis, would lead to the observed behaviour.

(2) Waite[5] has shown that reactions in condensed phases may be partly or wholly diffusion controlled, and that in such a case, though the rate may be expressed by a conventional 'mass action' equation, $R = k(A)(B)$, the rate constant k is no longer a true constant but varies with time. In view of the complex nature of the degradation of cellulose we may envisage several bi-molecular processes occurring and in so rigid a medium diffusion control is to be expected. If a repair mechanism behaved in this way, the *G* value versus dose curves could well have their observed form.

(3) We have found by electron spin resonance investigations that the concentration of unpaired spins in cellulose irradiated under conditions identical to those used for the gas yield work rises to a maximum within 10 Mrads and then remains sensibly constant. (This result is in agreement with a more detailed examination of electron spin resonance of irradiated cellulose recently published[6].) This would suggest that radical–radical reactions are occurring at an increasing rate during the early stages of irradiation, and if at least a proportion of such reactions remove hydrogen atoms, then the observed behaviour would result.

It is not proposed to present a detailed theory of cellulose radiolysis, since an examination of the solid residues, which is at present being carried out, should enable this to be done more reliably. In this connexion it is of interest to note that the *G* values for both chain breaks and acid production behave in a similar manner to the hydrogen yield and fall to a limiting value as the dose is increased.

MECHANISM OF FORMATION OF EXCITED CN IN ATOMIC REACTIONS

By DR. D. W. SETSER* and DR. B. A. THRUSH

Department of Physical Chemistry, University of Cambridge

MANY reactions involving free atoms yield excited species. In general, electronically excited species are commonly formed in recombination reactions, whereas the excitation of molecules formed in transfer reactions is normally vibrational rather than electronic. The following afterglow reactions are examples of recombinations which yield electronically excited species, active nitrogen from N+N (ref. 1), NO emission from N+O (ref. 2), air afterglow from O+NO (refs. 3 and 4), sulphur dioxide afterglow from O+SO (refs. 5 and 6) and HNO emission from H+NO (refs. 7 and 8). For some of these reactions, the radiating state does not correlate with ground-state atoms. In these cases, emission occurs from levels with energies below that corresponding to dissociation into normal atoms, and there is evidence that, during recombination, molecules are formed in excited electronic states which correlate with normal atoms and from which they can cross into the radiating state (this crossing is normally a radiationless process induced by collisions). It is to be expected that all the stable molecular states which can be formed from ground-state atoms will be populated when such atoms recombine as, apart from states which correlate via an avoided crossing, the only energy barrier to combination is that due to rotation which is normally negligible.

For diatomic molecules, the potential curves of excited states do not normally cross that of the ground state as the internuclear distance is increased. If potential surfaces for the atomic transfer reaction:

$$A + BC = AB + C$$

are constructed by one of the normal methods[9,10], it is found that the potential surface leading to an electronically excited state of AB lies above that leading to the ground state except where $r(A - B)$ approaches infinity. This is represented diagrammatically in Fig. 1*a*, which shows that the reaction yielding electronically excited AB would be expected to have a higher activation energy than that yielding AB in its electronic ground state.

Such arguments should also apply to atom transfer reactions involving polyatomic species, and it has recently been shown[11] that the transfer reaction

$$NO + O_3 = NO_2 + O_2$$

has an activation energy of 2·5 kcal/mole to yield ground-state NO_2 molecules and 4·2 kcal/mole for the formation of electronically excited NO_2 molecules which give the red emission characteristic of this reaction. In fact, very few transfer reactions which yield electronically excited species are known, and most exothermic transfer reactions which are known to produce excited products give instead molecules in their electronic ground states with excess vibrational energy in the newly formed bond, for example, $H + O_3$ (ref. 12), $O + ClO_2$, NO_2 (ref. 13), $O + O_3$ (ref. 14), $H + Cl_2$, Br_2 (ref. 15). The preferential formation of ground-state molecules is to be expected on the model given, but the presence of vibrational excitation is clearly a function of the shape of the potential surface near the saddle point and will not be discussed here.

A particularly interesting case is the mechanism of CN chemiluminescence which is observed in many reactions between active nitrogen and substances containing carbon. The reaction of active nitrogen with halogenated methanes

* Present address: Department of Chemistry, Kansas State University.

has been investigated in detail by Broida *et al.*[16,17], who have shown that, in these systems, excited CN radicals are formed almost exclusively in the $A^2\Pi$ state (which emits the CN red system) in vibrational levels up to $v' = 10$ They also showed that the $v' = 0$ level of the $B^2\Sigma^+$ state (which emits the CN violet system) is populated by collision-induced transitions from the adjacent levels of the $A^2\Pi$ state[18]. Bayes[19], who also investigated CN red emission from reactions involving active nitrogen, used the notation P_2 for this distribution, which has its maximum population at or near level $v' = 7$ of the $A^2\Pi$ state In the reaction of active nitrogen with HCN, C_2N_2 or ClCN he observed a different distribution which he classed as P_1 and showed it was not formed by the relaxation of the P_2 distribution.

We have recently made kinetic and spectroscopic investigations of these reactions and of the reaction of oxygen atoms with cyanogen, observing both CN red and violet systems in emission Our results confirm Bayes's conclusion that the CN red emission from these reactions can be classified as two groups, P_1 ($v' \leqslant 3$) and P_2($v' \geqslant 3$) We further find that each of these groups is associated with a characteristic distribution in the CN violet emission, the P_2 distribution corresponding to level $v' = 0$ of $B^2\Sigma^+$ being predominantly populated as observed by Broida[16-18] The P_1 distribution in the red system is accompanied by CN violet emission mainly from the higher levels of the $B^2\Sigma^+$ state, transitions from levels $v' = 5$ and 6 and the headless bands just above them being the most intense, the 'tail' bands are also observed decreasing in intensity from $v' = 11$ to $v' = 15$, which is the highest level seen In our experiments this emission and the associated P_1 red distribution predominated in those reactions where the parent molecule contained a CN group (that is, active nitrogen with HCN or C_2N_2 and O + C_2N_2), while the P_2 emission was dominant in the reaction of active nitrogen with halo-methanes where the CN bond was formed in the reaction The active nitrogen plus cyanogen chloride system showed both types of emission from both red and violet systems; this point is discussed later

The excitation energies involved in the CN violet emission which accompany the P_1 distribution are very high (133 kcal/mole for the fairly prominent $v' = 11$ level), and it is almost impossible to find reactions which are sufficiently exothermic to produce CN radicals with these amounts of energy from the CN-containing compounds used We therefore consider that these levels of the $B^2\Sigma^+$ state and the P_1 levels of the $A^2\Pi$ state which accompany them are populated in collisions between previously formed CN radicals and some excited species. This view is substantiated by the observation of NO emission from levels $v' = 0$ and 1 of the $A^2\Sigma^+$ state and $v' = 0$ of the $B^2\Pi$ state when NO is introduced into the O + C_2N_2 reaction showing that NO molecules are acquiring up to 133 kcal/mole of energy in collisions with some species A similar experiment is not feasible for reactions involving active nitrogen owing to the rapidity of the reaction[20]

$$\mathrm{N + NO = N_2 + O}$$

The large excitation energies involved and the fact that both CN and NO have an unpaired electron, which could assist spin reversal in another molecule during a collision, suggest that the species by which they are excited is the metastable triplet state of $N_2(^3\Sigma^+_u)$ which has an energy of 142 kcal/mole This species is known to be present in active nitrogen[21], and there is good reason to believe that it or CO molecules in the corresponding triplet state ($^3\Pi$), which has an energy of 139 kcal/mole, are formed in the O + C_2N_2 reaction. The ratio of the CN violet emission intensity to the red P_1 emission intensity showed some variation between different reactions suggesting that other species capable of exciting only the CN red system might be present.

The reaction between active nitrogen and halomethanes where CN bonds are formed during the reaction shows P_2 emission as a well-defined flame. For this and other reasons, they are believed to be chain reactions and the observed products are explained by a generalized chain mechanism of the type.

$$\begin{array}{llll}
\mathrm{N_2}^* & + \mathrm{C}X_4 & = \mathrm{C}X_3 & + X \\
X & + \mathrm{C}X_4 & = \mathrm{C}X_3 & + X_2 \\
\mathrm{CN} & + \mathrm{C}X_4 & = \mathrm{C}X_3 & + X\mathrm{CN} \\
\mathrm{N} & + \mathrm{C}X_3 & = X\mathrm{CN} & + 2X \\
X & + \mathrm{C}X_3 & = \mathrm{C}X_2 & + X_2 \\
X & + \mathrm{C}X_2 & = \mathrm{C}X & + X_2 \\
\mathrm{N} & + \mathrm{C}X_2 & = \mathrm{CN} & + X_2 \\
 & & = X\mathrm{CN} & + X \\
\mathrm{N} & + \mathrm{C}X & = \mathrm{CN} & + X
\end{array}$$

where X is H, Cl or Br Although the heats of formation of some of the species involved are not known, it is probable that all the essential reactions are exothermic if the parent molecule is a partly or fully halogenated hydrocarbon.

In this scheme, the last reaction is very exothermic. Accepting the lower of the two recently published values of D(C–N), that is, 174 kcal/mole (refs 22 and 23), rather than 184 kcal/mole (ref. 24), this reaction is 94 kcal/mole exothermic for X = H, at least 80 kcal/mole for X = Br (ref 25), and probably 80–90 kcal/mole exothermic for X = Cl, D(C—Cl) being unknown From previous observations it would be expected that this reaction would yield vibrationally rather than electronically excited CN radicals, however, CN is a somewhat unusual species, in that the $A^2\Pi$ state crosses the ground state ($X^2\Sigma^+$) at an internuclear distance of 1 50A and lies below it for greater nuclear separations[26]. If potential surfaces are constructed for this reaction

$$\mathrm{N} + \mathrm{C}X \rightarrow \mathrm{N - C} - X \rightarrow \mathrm{NC} + X$$

the surface leading to the $A^2\Pi$ state which emits the CN red system will lie below that leading to the ground state where $r(\mathrm{C-N}) > 1{\cdot}50A$, as illustrated in Fig. 1*b*. The intersection of the $A^2\Pi$ and $X^2\Sigma^+$ states occurs at an energy of 60 kcal/mole corresponding to level $v' = 7$

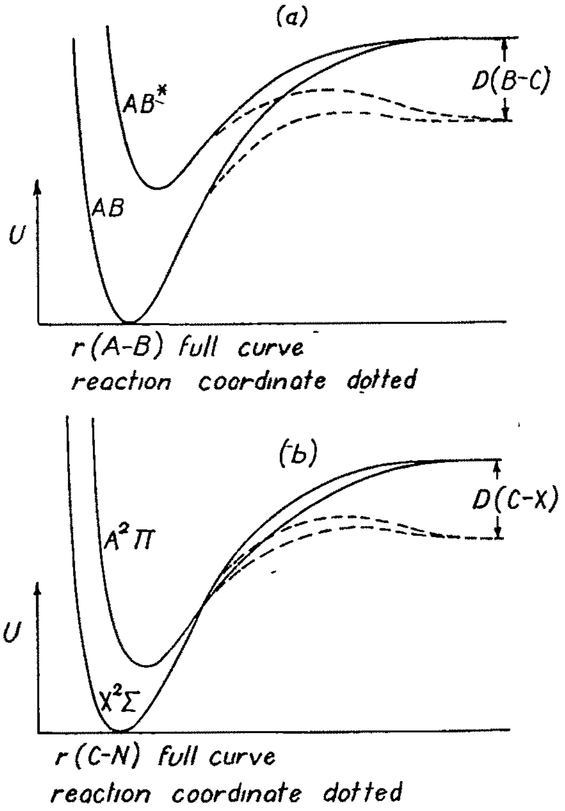

Fig 1

of the $A^2\Pi$ state, it is therefore to be expected that CN radicals formed with energies close to or greater than this will be produced preferentially in the $A^2\Pi$ state which gives the CN red emission. This reaction provides a convincing explanation of the P_2 distribution of the CN emission which has its maximum intensity at level v′ = 7 of the $A^2\Pi$ state and extends up to level v′ = 10 corresponding to an excitation energy of 74 kcal/mole It also explains why the $B^2\Sigma^+$ state, which has its outer limits at smaller internuclear distances than the $A^2\Pi$ state[26], is populated from the latter state rather than directly

In our experiments, the only other reaction which gave significant P_2 emission was that between active nitrogen and cyanogen chloride. While this is a complex reaction giving surface deposits, the P_2 emission is explained by the reactions

$$N + NCCl = N_2 + CCl$$
$$N + CCl = NC^* + Cl$$

The first reaction is exothermic, whereas the corresponding step for HCN would be thermoneutral and probably has a large activation energy.

Thus, the emission from high vibrational levels of CN violet systems including 'tail' bands and the associated P_1 red emission are believed to be due to collisional excitation of previously formed CN radicals By contrast, the P_2 emission is due to formation of electronically excited CN in $A^2\Pi$ state in a highly exothermic transfer reaction The crossing of potential curves which makes the latter process possible is due to the configurations of the states involved, the ground state $X^2\Sigma^+$ is $KK(\sigma g2s)^2(\sigma u2s)^2(\pi u2p)^4(\sigma g2p)$, while the $A^2\Pi$ state is . $(\pi u2p)^3(\sigma g2p)^2$ The promotion of an electron from the $\pi u2p$ to the $\sigma g2p$ orbital increases the bonding at greater internuclear distances but decreases it at shorter distances[27] (the u and g notation can be used since the transition $B \rightarrow A$ which is $^2\Sigma^+_u \rightarrow {}^2\Pi_u$ is not observed) C_2 is another molecule in which excited electronic states cross the ground state at large internuclear distances, and a similar explanation may hold for the 'high pressure' bands from the v′ = 6 level of the C_2 Swan system ($^3\Pi_g \rightarrow {}^3\Pi_u$) which can appear unaccompanied by other bands of C_2 under conditions when C atom concentrations are thought to be high[28]. It has been shown[29] that the recently discovered $^3\Sigma^-_g$ state of C_2 (ref 30) perturbs the v′ = 6 level of the $^3\Pi_g$ state It is likely that if C_2 molecules are formed with the appropriate energy in a reaction involving C atoms, they would be formed preferentially in the $^3\Sigma^-_g$ state (configuration . $(\pi u2p)^2(\sigma g2p)^2$), which at these energies has its outer turning point at a greater internuclear distance than to the ground state . . . $(\pi u2p)^4$, $^1\Sigma^+_g$ or the first excited state . $(\pi u2p)^3(\sigma g2p)$, $^3\Pi_u$ of C_2 Thus the selective excitation of the 'high pressure' bands of C_2 would be associated with a high population of the $^3\Sigma^-_g$ state which has only been observed by the infra-red $^3\Sigma^-_g \rightarrow {}^3\Pi_u$ emission[30]

We thank the National Science Foundation for a postdoctoral fellowship to one of us (D W S) and the Department of Scientific and Industrial Research for a special research grant

ANOMALOUS BEHAVIOUR OF SOME AMINO-ACIDS AS ICE NUCLEATORS

By N. BARTHAKUR and DR. J MAYBANK

Saskatchewan Research Council, Saskatoon, Canada

FOR a long time, certain inorganic compounds of hexagonal structure with lattice parameters similar to those of ice have been known as good cloud-seeding materials Recent work has shown that a few crystalline organic substances will nucleate ice almost as effectively as silver iodide Power and Power[1] were first to determine the nucleating efficiency of some amino-acids which nucleate ice from supercooled vapours at threshold temperatures as high as −4 5° C However, it was Schaefer[2] who first found proteins to be good ice nucleators Head[3,4] has claimed some steroids and α-phenazine to have excellent ice-nucleating properties. Mason and Fukuta[5] have recently investigated more closely the epitaxial growth of ice on organic crystalline substrates and found several steroids to be the most effective substances, forming ice crystals at temperatures close to −1° C Fukuta[6] has recently found metaldehyde to have remarkable ice-nucleation properties, producing ice crystals at temperatures as high as −0 4° C

Several fundamental nucleation techniques were utilized in the present work to investigate more closely variations in the behaviour of some amino-acids as ice nucleators with the view of their practical utility as potential cloud-seeding agents Following the technique of Mason and Maybank[7], mixing cloud chamber tests were carried out using wire-supported supercooled soap films as detectors of ice crystals or active ice nuclei

The appearance of one crystal in 10^4 particles was arbitrarily defined as the threshold for activity for each substance Each compound was tested for ice-nucleating ability at −18° C, and then at successively higher temperatures to determine a threshold for their activity The relevant temperatures were measured within a centimetre of the film surface using a copper–constantan thermocouple No significant difference in results was obtained by using as detectors dishes of supercooled sugar solution enclosed in a copper cylinder Supercooled sugar solution has an advantage over the soap film technique due to the slower growth-rate of the ice crystals.

As recent research has indicated the occurrence of some amino-acids in trace amounts in the atmosphere[8,9], some of these simpler, naturally occurring compounds were first tested for their activity. Peptides, which are polymers that contain only a small number of amino-acid units, were then selected for similar experiments. Table 1 gives the threshold temperatures for ice nucleation of those amino-acids and peptides found to be active at or above −10° C. The bulk water freezing temperatures were determined for these compounds by observing the freezing behaviour of millimetre-size water drops containing suspended particles of each test material. The mean supercooling values so obtained are also listed in Table 1 in order of increasing activity.

Table 1

Compound	Solubility (g/100 g of water)	Mixing chamber threshold temperature (°C)	Bulk water freezing temperature (°C)
L-Valine	5·36 at 20° C	−7·0	−15·0
D-Valine	9·15 at 16·5° C	−6·0	−14·5
L-Tryptophan	1·14 at 25° C	−5·0	−13·5
DL-Tryptophan	Slightly soluble in cold water	−10·0	−12·5
Glycine	25·3 at 25° C	−10·0	−12·0
Glycyl-DL-serine	—	−7·5	−7·0
L-Leucylglycine	—	−6·5	−6·0
L-Isoleucine	4·12 at 25° C	−6·0	−6·0
D-Isoleucine	4·12 at 25° C	−6·5	−6·0
L-Leucine	2·43 at 25° C	−5·0	−5·0
D-Leucine	2·02 at 19° C	−5·5	−5·0
L-Methionine	—	−5·0	−5·0
D-Methionine	—	−5·0	−5·0

Out of 40 amino-acids chosen for investigation, it was found that the racemic variety is generally less effective than the optically active type. D-Leucine and L-leucine nucleated ice at −5·5° C and −5·0° C respectively, whereas DL-leucine gave a threshold temperature of −12·0° C. Similar results are found for valine, isoleucine and tryptophan. Differently prepared samples of DL-leucine were tested for their activity and found to yield varying threshold temperatures. This might be due to the dependence of nucleating site density and crystal form on the method of preparation.

Efficient cloud-seeding nuclei require stability in sunlight. Two-hour exposures to a 550-W mercury vapour lamp at 20 cm or to strong sunlight produced no significant change in activity of the powdered samples.

Table 1 shows, for the first five compounds, the discrepancy between the threshold temperature obtained from the freezing of supercooled water vapour and that of bulk water. This is particularly pronounced in L-valine, D-valine (each of which possessed a very well marked onset of activity in the mixing chamber) and L-tryptophan. Maybank[10] observed a similar effect in the case of three clay minerals, namely, gibbsite, kaolinite and vaterite, and concluded that the freezing ability of a particular nucleus is dependent on the manner in which it is introduced into the supercooled water droplets, particularly if solubility is a factor. The discrepancy with some of the amino-acids might be explained in a similar way.

Serine, tyrosine, cysteine and threonine are all found to be inactive, regardless of their stereoisomers. Several peptides such as DL-phenylalanylglycine and glycyl-L-leucine were observed to have moderate threshold temperatures of −11° and −12° C, respectively. Despite the fact that serine was ineffective, glycyl-DL-serine gave a fairly consistent threshold temperature of −7·5° C.

It is interesting to note that glycine, alanine and other amino-acids have been recently reported to be synthesized in the laboratory by irradiating simpler compounds[11]. It is suggested that amino-acids, the origin of which in the atmosphere, rain and snow is yet unknown, might be synthesized by radiation and by lightning discharge, thus influencing the precipitation mechanism by the formation of additional ice nuclei.

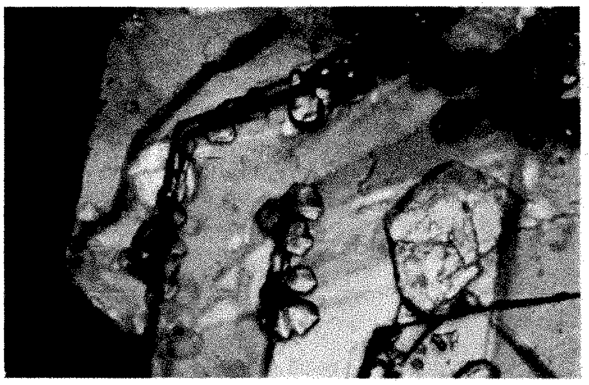

Fig. 1. Pseudo-hexagonal ice crystals growing preferentially on the steps of a D-leucine substrate at −15° C. (× c. 190)

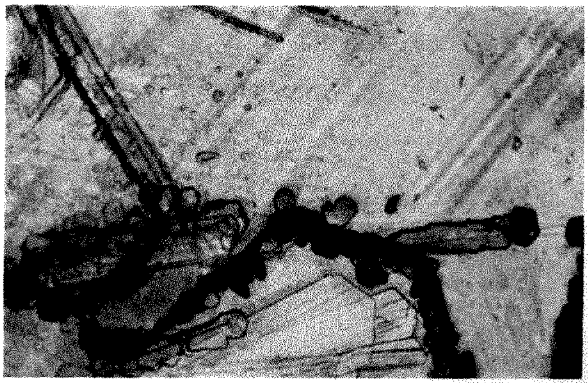

Fig. 2. Oriented ice crystals on D-valine at −15° C showing preferential nucleation at shrinkage cracks. (× c. 470)

Epitaxial growth of ice on amino-acid substrates was investigated in the microscope cold-stage and is illustrated by the photo-micrographs in Figs. 1 and 2. Ice crystals were found to grow preferentially on the steps and shrinkage cracks of the organic substrates. Certain crystals showing many active sites were taken for close observation. Ice crystals appeared and grew usually only on a few active sites, leaving the other sites free of ice. By varying supersaturation and temperature, no difference in behaviour was observed. By repeatedly growing and melting ice on the substrate, under apparently identical conditions, the sites previously active became less and less so, while other sites gradually became nucleating centres. Decreasing activation might result from the fact that many amino-acids are soluble in water, although in some cases only with difficulty in cold water; so during the process of repeated growth and evaporation of the ice crystals on the substrate the active sites were simply being destroyed by water solvation.

Experiments conducted to ascertain whether certain particles act as sublimation or freezing nuclei produced inconclusive results. In the temperature range of 0° C to −30° C, water vapour was always observed to condense on the substrate and then afterwards freeze. Below this temperature range, it was found very difficult to decide whether water vapour was first condensed or not. Unlike mica[12], no part of any of numerous amino-acid crystals investigated was found to permit ice crystals to survive in an unsaturated atmosphere. This might be an indication that amino-acid crystals will not act as sublimation nuclei.

Nucleation has been shown to occur with compounds possessing —OH, =O, —NH_2 groups. Amino-acids fall into this category. Ice-nucleating ability of these organic substances is not yet well understood. From the investigation reported here, it does not appear to be closely related to their lattice geometry. Disregistry between various amino-acid nucleants and ice crystals is found to be well beyond the effective region of 0·005–0·015, where ice crystals grow coherently on substrates according to Turnbull and Vonnegut[13]. Designating the interfacial energy between the substrate and the crystal as σ_{sc}, it may be written as the sum of two terms:

$$\sigma_{sc} = \gamma + \alpha\,(\delta - \varepsilon)$$

where γ is an interaction term due to different bond type, chemistry, etc., and $(\delta - \varepsilon)$ is a structural term, with δ the disregistry between the substrate and forming crystal on low-index planes of similar atomic arrangement. In this equation $\varepsilon = \dfrac{(a - a_0)}{a_0}$, where a_0 and a are the lattice parameters of the nucleus in the strain-free and strained condition, respectively. Vonnegut[13] determined the value of α to be 180 ergs/cm². For amino-acid substrates, it could be the first term γ which plays the most important part. As was pointed out by Mason and Fukuta[5], the important factors determining the nucleating ability of these compounds are the presence and arrangement of hydrogen bonding groups on their surfaces. The exposure of different bonding groups at the steps and cracks might explain why they are preferred sites for the ice-nucleation mechanism, despite the fact that crystal dissymmetry is not itself apparently important.

This work was supported by a research grant from the Meteorological Branch, Canada Department of Transport, and one of us (N. B.) is a postgraduate student at the University of Saskatchewan. We thank Dr. W. B. McConnell of the National Research Council, Saskatoon, for kindly providing us with some samples of amino-acids and peptides.

RHEOLOGY OF DILUTE AQUEOUS SUSPENSIONS OF SOME REACTIVE SOLIDS

By A. K. CHATTERJI and G. W. KAPSE

Central Building Research Institute, Roorkee (U.P.) India

WE have made some rheological measurements of dilute aqueous suspensions of some solids which react with water (as lime, Portland cement and plaster of Paris). It is found that, when the reaction occurs for a short time, the plastic viscosity of these suspensions (which are non-Newtonian in character) can be altered to a large extent by accelerating or retarding the reaction rate of the material with water. Acceleration of the reaction increases the viscosity and its retardation has the opposite effect.

Results are explained on the assumption that reaction between these materials and water is a chemisorption process. In such a process the position of the bulk Fermi-level of the particles controls the coverage of chemisorbed molecules. Further, when the water molecules are adsorbed on the surface of the particles, they have their charged groups protruding outwards. These groups help to orient the water molecules in the region immediately surrounding the particles, and the layers of water there are stabilized. Acceleration of the reaction leads to stabilization of the structure of water in a larger volume than would have happened if the reaction were allowed to proceed normally. Increased extent of stabilization of water lattice may be responsible for enhanced viscosity when the reaction rate is augmented. When the reaction rate is lowered, the coverage being smaller than when the reaction rate was normal, the volume over which water structure gets stabilized is smaller than that which would have been normal, and lowering of viscosity of the suspension is observed.

Forslind's view[1] about the viscosity of hydrogels appears to be applicable in such dilute suspensions. The present view, in addition, stresses the importance of the position of Fermi-level in the reacting particles, and it is concluded that the rheological properties of dilute aqueous suspensions of solids, which react with water by the chemisorption process when the reaction products are not formed in sufficiently large quantities as to alter the water structure, are governed by the position of the bulk Fermi-level of the particle in suspension.

Materials used in these experiments are (*a*) lime (CaO); (*b*) normal Portland cement; (*c*) plaster of Paris; and these were prepared as follows: (*a*) Lime was obtained by heating AnalaR calcium carbonate at 900°–1,000° C for 4 h. The mass obtained was powdered and sieved in B.S.300 mesh and the portion passing was used in all subsequent operations. Portions of the powder thus obtained were heated separately with 0·1 per cent NiO and with 1 per cent ZnO at 800° C for 4 h. (*b*) Normal Portland cement was sieved in B.S.300 mesh and the fraction passing was used. (*c*) Plaster of Paris ($CaSO_4$,1/2H_2O) was prepared by heating $CaSO_4 2H_2O$ at 170°–180° C for 1 h. As a given material was drawn from the same lot and as no sintering could be detected on heating, the specific surface area of the materials used in a particular set of experiments was taken to have remained unaltered.

The rate of reaction of these materials with water was changed as follows. (1) With lime: (i) for acceleration, (*a*) activated lime (heated with NiO) was taken; (*b*) 0·104 per cent of sodium acetate (an accelerator) was mixed with water; (ii) for retardation, (*a*) deactivated lime (heated with ZnO) was taken; (*b*) 0·5 per cent sucrose (retarder) was mixed with water. (2) With cement: 3 per cent $CaCl_2$ was mixed with water for acceleration and 0·9 per cent sucrose for retardation. (3) With plaster of Paris: 0·118 per cent and 0·15 per cent boric acid were used as retarders and 0·148 per cent and 0·17 per cent of K_2SO_4 were used as accelerators. Percentages are by weight of the material.

Rheological measurements were carried out by the multiple point method using a rotational viscosimeter (MacMichael viscosimeter) in which only low shearing rates could be used. The speed of the rotating cup was varied from 5 to 40 revolutions per minute. The rotating cup has an internal diameter of 2·50 cm, and a bob 2·00 cm diameter was selected for use. The bob was immersed to a depth of 4·50 cm in the dispersion under test, in all the experiments. Torsion wire No. 26 was used for plaster of Paris dispersions and wire Nos. 28 and 34 were used for the lime and cement dispersions.

All measurements were carried out at 27° ± 0·5° C and 50 per cent relative humidity. Deionized distilled water was used throughout. The water-to-material ratio was taken as· lime, 4 : 1, cement, 3 3 1; and for plaster of Paris, 3 : 1 and 4 1.

The material was dispersed by stirring it in the required quantity of water or solution for 10 min, the temperature being maintained between 26·5° C and 27° C The dispersion was then quickly poured into the annular space between the cup and the bob of the viscosimeter, and measurement of deflexion was started at the lowest rate of rotation. The latter was raised to the next higher stage of choice and the deflexion noted This was continued until the highest rate of rotation was reached. The deflexion with decreasing speed of rotation was then noted. The time taken to change from one rate of rotation to another was kept constant The entire measurement comprising both increase and decrease in speed was completed in 2·5–2 75 min, and this time was kept similar in all the samples.

Results are given in Figs 1, 2, 3 and 4. As the rate of shear is proportional to the rate of rotation and the torque to the deflexion produced, the results are given as plots between rotation per min and the deflexion.

Fig 1 gives the results for lime. It will be seen that compared with the deflexions (at a given speed) for the suspension of normal lime (curve *a*), the deflexions for NiO-treated lime suspension (curve *b*) and the suspension with accelerator (curve *c*) are greater and those for the suspension of lime treated with ZnO (curve *d*) and for the suspension of lime with retarder (curve *e*) are less. Fig 2 shows the results of measurements on cement dispersions. Curve (*a*) gives the behaviour of normal Portland cement dispersed in water, curve (*b*) when an accelerator ($CaCl_2$) has been added It is seen that the deflexion in this case is less than that for normal cement When sucrose (a retarder) is added, at lower rates of rotation, the deflexion decreases, and at higher rates the deflexion initially tends to equal and then to exceed the deflexion (curve *c*) found in dispersion of normal Portland cement Figs 3 and 4 show the results with dispersions of plaster of Paris. Curves (*a*) in these figures are for suspensions of plaster of Paris as such Curves (*b*) are for those suspensions in which accelerators were added and the curves (*c*) are for those in which retarders were used A change in mixing times from 1 min (Fig. 3) to 10 min (Fig. 4) shows that with increased mixing time the dispersion behaves as a dilatant when accelerator is used.

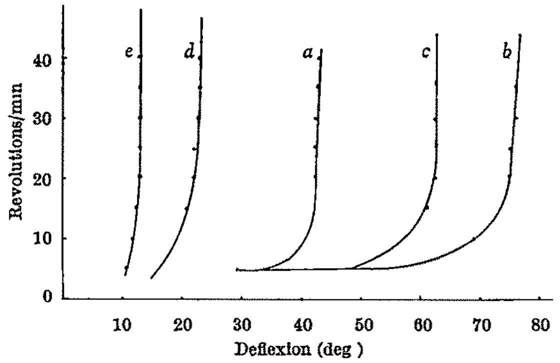

Fig 1 Suspension of lime in water
Curve (*a*) for normal lime, (*b*) for lime treated with NiO, (*c*) for lime with sodium acetate (accelerator), (*d*) for lime treated with ZnO, (*e*) for lime with sucrose (retarder)

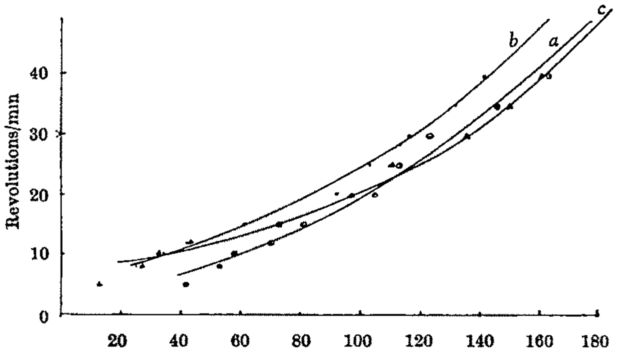

Fig 2 Suspension of cement in water
Curve (*a*) for normal Portland cement, (*b*) with $CaCl_2$ (an accelerator), (*c*) with sucrose (a retarder)

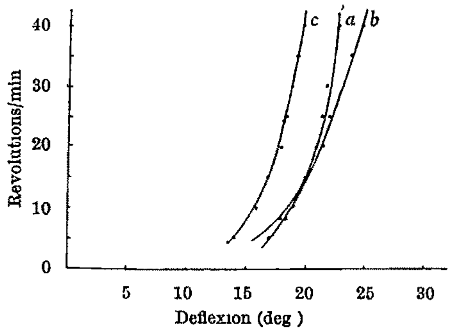

Fig 3 Suspension of plaster of Paris in water Mixing time, 1 min (*a*) Normal plaster of Paris, (*b*) with K_2SO_4 0 148 per cent (accelerator), (*c*) with boric acid 0 118 per cent (retarder)

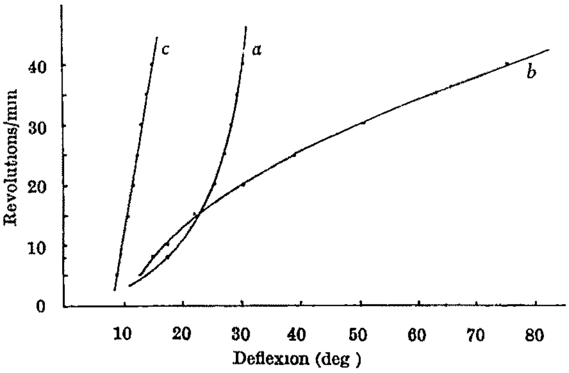

Fig 4 Suspension of plaster of Paris in water Mixing time 10 min (*a*) Normal plaster of Paris, (*b*) with K_2SO_4 0 17 per cent (accelerator), (*c*) with boric acid 0 15 per cent (retarder)

The change in the deflexion produced in the solutions of chemicals, used as accelerator or retarder, compared with the deflexion produced with deionized distilled water is about 1 per cent

When lime is heated with NiO and ZnO, the reactivity of lime so produced with water is enhanced or decreased respectively[2], such treatment also raises or lowers the Fermi-level of lime[2] When lime is treated with NiO, viscosity of the suspension increases, and when it is treated with ZnO the viscosity decreases Again, when an accelerator (sodium acetate) is added viscosity increases, and the reverse occurs with the addition of a retarder (sucrose) to the suspension Since a rise or fall in the Fermi-level of lime crystal enhances or lowers the reactivity of lime with water, the function of agents which accelerate or retard the reaction between lime and water is probably to raise or lower the Fermi-level of lime crystal except where retardation is due to purely physical obstruction

Coverage of adsorbed water molecules on the surface of lime (*n*-type semiconductor) is larger the higher its Fermi-level The reverse occurs when the Fermi-level is lowered This adsorbed layer of water influences the molecules of water in immediate surroundings of the crystal to form stable layers with the molecules in them having some degree of orientation With larger coverage, the volume of the medium having stabilized water layer also increases, and retardation of reaction, which occurs through a lowering of Fermi-level, results in a decrease of the volume having stabilized water layer Stabilization of larger volume water lattice increases the viscosity of the suspension and a decrease in the volume of stabilized water lowers it.

As the reaction is allowed to proceed only for a short while, the possibility of calcium ions disturbing the water lattice is low. Thus, the result of these measurements on the lime–water suspensions represents the influence of rate of interaction of the suspended lime with water on the viscosity of such suspensions

When an accelerator ($CaCl_2$) is used along with normal Portland cement the deflexion, at a given rate of revolution, is reduced This may occur because of loosening of the water structure by chlorine ions[1] and also by removal of calcium ions by the clinker crystals by adsorption The latter may occur through capture of 'holes' by the adsorbed ions from the clinker minerals on the same line as the adsorption of lime from aqueous solutions by Fe_2O_3 (*p*-type reaction)[3] Actual transfer may occur through (OH) groups associated with calcium ions As the clinker minerals lose 'holes'. the position of Fermi-level in these crystals is raised and their reactivity with water is enhanced[4] in the same manner as the acceleration of setting of Portland cement occurs when chrysotile asbestos is present[5] Thus it appears that the acceleration of setting of cement (and the retardation, too) through chemical action may find explanation from the instantaneous position of the Fermi-level in the clinker minerals when these minerals react with water Sucrose may retard the reaction between lime and water if the HO—C—H groups in sucrose get adsorbed on the lime surface through an 'acceptor' type reaction Fermi-level is lowered and retardation of the reaction between lime and water becomes possible Among the clinker minerals in Portland cement, as di- and tri-calcium silicate and tri-calcium aluminate, evidences are in favour of higher density of conduction electron in the latter two minerals[4] With di-calcium silicate, then, the possibility of an 'acceptor' type reaction is less than with the other two minerals, and hence the cause of retardation of setting of cement by sucrose may possibly be both physical and chemical Formation of a surface precipitate will mechanically hinder the reaction with water of di-calcium silicate, while the reactions with tri-calcium aluminate and silicate will be retarded by the chemisorption process on the same lines as in lime This clarifies the views expressed regarding the mechanism of the action of sucrose as a retarder of the setting process in Portland cement[6] Observed lowering of viscosity of cement suspension on addition of sucrose at low speeds can then be explained as due to both mechanical hindrance provided by the surface precipitates on di-calcium silicate and chemisorption on others At higher speeds, precipitates (of sucrose) are thrown out, which goes into the solution and enhances the viscosity due to its own account[7] and also due to enhanced reaction rate

For plaster of Paris, addition of an accelerator (K_2SO_4) increases the viscosity, while the effect of a retarder (boric acid) is to lower it These facts may also be explained on the same principles, and on this basis the initial reaction between plaster of Paris and water should be considered as a solid–liquid reaction This confirms the views of Hansen[8]

The results are thus explained on the assumption that the reaction between these materials and water is a chemisorption process A chemisorbed layer of water is responsible for the stabilization of water lattice The rheological property of the suspension will be governed by how far the absorbed layer of water is able to stabilize the water structure Incidentally, an explanation of the action of accelerators and retarders on setting of cement has been given on the basis of chemisorption of the ions added As these chemisorption processes are governed by the position of the Fermi-level in the suspended particle, the position of the Fermi-level in the solids is considered to be the factor controlling the rheological behaviour of dilute suspensions of materials which react with water by the chemisorption process, as well as controlling the acceleration and retardation of the setting process of cement.

ENHANCEMENT OF LIGHT OUTPUT FROM A SUPERNOVA

By Dr S A. COLGATE
Lawrence Radiation Laboratory, University of California, Livermore, California
AND
Dr. A G. W. CAMERON
Goddard Institute for Space Studies, National Aeronautics and Space Administration, New York

INTEREST has been aroused by the discovery that certain radio sources are associated with superluminous objects in distant galaxies In particular, the source *3C* 273 is 8–9 astronomical magnitudes brighter than a supernova explosion at the maximum of the light curve[1], and much of the emitted light appears to be synchrotron radiation[2] Occasional flares occur in the light curve of this object, during which an excess energy of $\sim 2 \times 10^{46}$ ergs/sec is emitted within an interval of 10^5–10^6 sec[1]

Among suggestions which have recently been made to account for the large energy radiated by strong radio sources we may mention the following three

(1) A chain reaction in a compact cluster of older stars in which one Type I supernova explosion triggers another[3]

(2) Collective formation of a cluster of more massive stars with similar evolutionary time-scales, which results in numerous Type II supernova explosions in a limited period of time[4]

(3) Formation of a very massive star (10^6–10^8 $M_\odot$), which implodes, releasing a substantial fraction of its rest-mass energy[5]

We have investigated a possible mechanism within the framework of the second of the above theories which may be able to account for the intense light flashes observed in *3C* 273 (ref 1) A normal Type II supernova explosion would not be visible against the strong light output from the *3C* 273 object However, the energy in one of the light flashes is the same order of magnitude as the expected kinetic energy in the ejected envelope from a star of 10–100 $M_\odot$ which undergoes a Type II supernova explosion If occasionally circumstellar gas of density $\sim 10^{-16}$ g/cm^3 accumulates in a very compact cluster of massive stars, then the interaction of the shock-ejected stellar envelope with such a gas could convert much of the kinetic energy into visible light in the required period of time The postulated gas density is much higher than

Integrating Microdensitometer

The Barr & Stroud Integrating Microdensitometer determines the amount of stained material, frequently DNA, in a cell or nucleus by measuring light absorption. By using refined techniques, including scanning and electronic integration, it produces extremely accurate results which can be used to calculate the total amount of stained material present. It has already found application in many laboratories throughout the world. Write for pamphlet 1239c/N.

* * *

Histogram of the absorbence of sixty isolated cells of rat liver, mostly lying at the 2c value with a few at the 4c value. Smear of cells was stained by the Feulgen method.

The measurement of colour

BY W. D. WRIGHT

For the third edition of his now standard textbook, Professor Wright has revised the text and made several substantial additions
Of particular importance are the new tables of data for the 10-degree C I E. system of colour specification. The edition has some interesting new colour plates

THIRD EDITION, 300 pages, 60s net

Ballet and Business

Don't mix. Or do they? Today even the director of ballet must watch his business step. And the businessman may discard his cares at the ballet. Both worlds meet in the comprehensive pages of The Financial Times. From down-to-earth features and surveys to keep every type of person up-to-date with the business and economic scene, to intelligent and lively reportage of leisure interest, the arts and entertainment, there's so much more to The Financial Times than its name implies.

Read **THE FINANCIAL TIMES** with profit—every day.

normal interstellar gas densities, which assures us that this mechanism will have only a rare occurrence, but it would not be surprising to have such a density accumulate in a region such as that under discussion.

The short time-scale of the light flashes indicates that the energy must be released in a rather small volume of space Solar flares are believed to result from the annihilation of magnetic field energy in the solar corona, they last for $\sim 10^3$ seconds The annihilation time varies as the square of the dimensions of the annihilation region. The amount of energy released in a *3C* 273 light flash is so many orders of magnitude greater than that in a solar flare, and the duration is so little greater that it is extremely unlikely that there is any similarity in the processes It seems very unlikely that the light flash energy can be stored in space and released by any triggering mechanism, such storage would have to exceed 200 ergs/cm^3 in the volume that could be illuminated by a light pulse in 10^6 sec

Our philosophy in selecting the most likely origin of the light flash has been to minimize the necessary energy content of the space within which the light flash is to be produced The following crude analysis indicates that much of the kinetic energy of a shock-ejected supernova envelope (from a Type II explosion) can be converted into visible light if a significant fraction of the envelope is slowed by collision with circumstellar gases

Massive stars are believed to undergo implosions, that initiate Type II supernova explosions, when nuclear evolution has converted their cores to iron, and the temperature has risen sufficiently to start the endothermic conversion of the iron to helium[6] We have found that the implosion of the core continues until ordinary nuclear densities are somewhat exceeded[7,8] In a recent theory by one of us[9], the deposition in the envelope of the energy of the neutrino flux from inverse β-decay in the collapsing core permits a fraction (~ 10 per cent) of the rest mass of the core to be converted into kinetic energy of expansion The core is that fraction of the star that collapses adiabatically and in these calculations it has been ~ 20 per cent of the total mass Thus a total energy release of several solar rest masses ($\sim 3 \times 10^{54}$ ergs) is predicted The time of this release ($\sim 10^{-3}$–10^{-2} sec) is short enough so that a shock wave necessarily forms in the star external to the core

Initially the shock wave will not be strong enough either to reverse the implosion of the matter or to eject it from the gravitational potential However, as it proceeds outward it increases in strength both because of the density gradient and because of the additional neutrino energy deposition At some point the shock becomes strong enough not only to reverse the imploding velocity but also to overcome the gravitational potential The matter corresponding to this point asymptotically approaches final velocity after leaving the star, but the shock strength which accelerated it corresponded to the gravitational energy per gram at the time of shock passage If nearly all the mass of the star is ejected, the mean energy of the shock becomes $\sim c^2/50$ erg/g The corresponding mean ejection velocity for the bulk of the mass of the star would be $u_0 = 4 \times 10^9$ cm/sec Consequently, only a two-fold increase in the strength of the shock as it proceeds in the density gradient of the envelope results in matter ejected with this velocity

The increasing strength of such a shock as it proceeds in the envelope has been previously calculated in detail[10] The resulting velocity distribution in the non-relativistic region can be approximated by

$$u = u_0\left(\frac{10M}{M_0}\right)^{-1/5.5}, M \leqslant M_0/10 \qquad (1)$$

where M is the integral mass external to the matter the velocity of which is u, and u_0 is the mean velocity of ejection (4×10^9 cm/sec for 100 solar masses)

If circumstellar gas of low density ρ surrounds the supernova, then half the incident shock energy $Mu^2/2$ will be converted into heat in a distance R, such that $M = 4\pi R^3\rho/3$, in a time $\tau = R/3u$ sec The factor 3 in the denominator of the last expression makes allowance for the fact that most of the volume of the sphere is at a substantial fraction of R

The heat deposited behind the shock may alternately be retained by the fluid or in the opposite limit may be completely radiated away If the heat is retained, then in a spherically divergent flow the gas expands and the heat is converted into kinetic energy, leaving only a small fraction to be radiated away when the expansion causes the gas to become transparent In the present problem we seek the opposite limit where the energy is radiated at the rate of deposition. Two conditions ensure this rapid radiation limit (1) At thermal equilibrium, the radiation energy density Q is larger than the particle energy density (2) The radiation mean free path (λ) is larger than the particle thermal relaxation length (l) behind the shock

The last condition ensures that the thermal energy gradient at the shock front is at least as steep as Q/λ, and the first condition ensures that with this gradient the heat flow $Qc/4$ will be greater than the shock heating rate $Q(u_s - u_f)$, where u_s is the shock velocity and u_f is the fluid velocity behind the shock For u_s, $u_f \ll c$

$$\frac{u_s - u_f}{u_s} = \frac{\gamma - 1}{\gamma + 1} = (\text{compression})^{-1} \qquad (2)$$

so that $Qc/4$ is always greater than the shock heating rate

We shall assume that thermodynamic equilibrium prevails, and then examine this requirement to find the conditions that optimize the visible radiant energy flux

If we assume a uniform density distribution and a mass equal to the incident mass, the total radiation rate becomes

$$W_t = \frac{Mu^2/2}{\tau} = \frac{1.5Mu^3}{R} = 0.4m^{0.45}u_0^3M_0^{0.55} \text{ erg/sec} \qquad (3)$$

which becomes as large as possible at the maximum ejected mass, $M = M_0/10$, giving:

$$W_{t\,\max} = 0.15\,\frac{M_0u_0^3}{R} \text{ erg/sec} \qquad (4)$$

The maximum spectral fraction will be radiated in the visible when $3kT = h\nu = 5 \times 10^{-12}$ erg; or $T = 1$ eV

The initial density ρ_0 corresponding to this radiation rate is determined by

$$caT^4/4 = \rho_0u^3/2$$

or

$$\rho_0 = \frac{1.1 \times 10^{-4}T^4}{u_0^3} \qquad (5)$$

The radius for equal mass at this density is determined by

$$4\pi R^3\rho_0/3 = M_0/10 \qquad (6)$$

giving:

$$W_{t\,\max} = 0.033u_0^2M_0^{2/3}T^{4/3} \text{ erg/sec} \qquad (7)$$

Choosing $T = 1$ eV, $u_0 = 4 \times 10^9$ cm/sec, and $M_0 = 100\,M_\odot$ gives $W_t = 5 \times 10^{46}$ ergs/sec, mostly in the visible at a radius $R = 3 \times 10^{16}$ cm

The assumption of equilibrium must be examined for these conditions

In general, the ion slowing-down path-length due to dynamic friction with the shocked plasma electrons is small compared with the total gas thickness, provided the electron temperature is held below 5 keV by radiation Since the relative ion energy is 8 MeV, this condition requires that the electrons radiate at least $10^3\ kT_e$ However, either the electron temperature must be in equilibrium with the radiation at a few eV, or low-energy (a few eV) bound–bound transitions must be available for non-equilibrium radiation as in the solar corona For the latter case to be effective, the high atomic number species must not be completely stripped of bound electrons (three or more must remain bound) This latter condition for the carbon–nitrogen–oxygen group requires $T_e \leqslant 50$ eV, so that again radiation in the visible requires a relatively low electron temperature One is forced to the conclusion that should the electron temperature rise above 100 eV behind the shock front, the visible radiation would become a small fraction of the total, and indeed the remaining radiation process, bremsstrahlung with Compton scattering, is small enough so that the electron temperature would run away to such a high value, $\gg 10$ keV, that the ion slowing-down length would become larger than the gas thickness, and no further shock would occur.

Therefore, we must demonstrate a self-consistent radiation loss rate large enough to maintain a low electron temperature at the heating rate of the shock (equation (5))

The collisional shock thickness is determined by the dynamic friction between the electrons of the shocked plasma and the incident ions of the cold gas

According to Spitzer[11], the energy loss time of a test charge of mass M and velocity u large compared with the thermal electron velocity of an ionized plasma becomes

$$\tau_s = \frac{u^3 M^2}{(M/m) 8\pi e^4 n_e z^2 z_1^2 \ln \Lambda} \text{ sec} \tag{8}$$

For the low densities involved, $\ln \Lambda \simeq 20$, and taking $z = z_1 = 1$, the slowing-down length becomes:

$$L = \tau_s u = 5\ 7 \times 10^{-17} u^4 / n_e \text{ cm} \tag{9}$$

or:

$$L = 10^{-40} u^4 / \rho_0 \text{ cm} \tag{10}$$

For the conditions of (6) and (7) this gives

$$L/R = 4\ 5 \times 10^{-3} \tag{11}$$

which confirms that there is a small fractional shock thickness, provided the radiation cooling is adequate.

The principal radiation loss from such a low-density plasma will occur due to the excitation of bound–bound transitions of the small fraction of high atomic number elements $z \geqslant 3$. If we assume an element composition similar to that of solar matter, then the CNO fraction, $f = 10^{-3}$, becomes the dominant radiation source For transparent plasmas in the temperature range 5–50 eV, extensive studies of radiation loss from low-lying resonant transitions[12,13] show that the effects can be approximated by an effective allowed transition of 10 eV with a cross-section of 10^{-15} cm^2 for each atom If the calculated radiation rate is then greater than the shock heating rate[7], the electron temperature will fall to a low enough value so that the radiation rate is limited to partial blackbody radiation with a larger fraction in the visible

The energy radiation rate becomes

$$W = (\text{volume})\, n_e n_i\, \overline{\sigma v_e}\, (h\nu) \text{ erg/sec} \tag{12}$$

With the assumption that nearly all the internal energy is radiated behind the shock, the shock compression would approach infinity However, an upper limit is determined by the shock thickness, since a thinner layer would be subject to Taylor instability The compression then becomes R/L and the 'transparent' radiation rate becomes

$$W_R = 4\pi R^2 L f\, [6 \times 10^{23}\, (R/L)\, \rho_0]^2\, \overline{\sigma v}\, (h\nu) \text{ erg/sec} \tag{13}$$

Using condition (6), which maximizes the total available energy, and evaluating $\overline{\sigma v}$ for $5 \leqslant T_e \leqslant 50$ eV as 3×10^{-7} cm^3/sec results in

$$W_R = 2\ 7 \times 10^{65} \frac{f M_0^3}{u^4 R^5} \text{ erg/sec} \tag{14}$$

Comparing this with the energy generation rate of the shock (equation (4)) shows that for radii less than the maximum $R_{\max}$ the resonant radiation can be greater than the shock rate Therefore, the stability condition for a radiation-cooled shock can be met and the maximum radius becomes.

$$R_{\max} = 3\ 7 \times 10^{16} f^{1/4} M_0^{1/2} u^{-7/4} \text{ cm}$$

which for $f = 10^{-3}$, $M_0 = 100\, M_{\odot}$, and $u = 4 \times 10^9$, gives $R_{\max} = 3\ 7 \times 10^{16}$ cm and a radiation rate of 5×10^{46} ergs/sec

At least 90 per cent of this radiation at the maximum radius will be in the ultra-violet, but at smaller radii the electron temperature will be reduced and a larger fraction will be in the visible. Consequently, it appears feasible to radiate an amount of energy from a shell interacting with circumstellar gas comparable with the amount measured by Smith and Hoffleit[1]

In addition, it can be noted that the thickness of the required circumstellar gas is small enough ($\leqslant 10$ g/cm^2) so that the cosmic ray spectrum that may be produced by the shocked outer layers of the supernova[10] will be only slightly modified

For general consistency, it is desirable to show that the model of a supernova explosion used here leads to the usual luminosity of a Type II supernova at the maximum of the light curve, if there is no circumstellar gas present The absolute photographic luminosity of a Type II supernova at maximum is approximately -18 (ref 14) corresponding to an energy emission in the photographic wavelength range of slightly less than 10^{43} ergs/sec We may estimate the light emission from the expanding envelope in a very crude way by considering the decrease in temperature of the shock-heated envelope as it expands adiabatically, and by assuming that this temperature is also characteristic of the expanding envelope at optical depths near unity

We have seen that the outermost layers of the pre-supernova are accelerated to near-relativistic velocities. Hence, after shock ejection, such layers will rapidly become optically thin while the temperature is very high. The bulk of the material is ejected at smaller velocities, and, as a result of the contraction of the inner parts of the pre-supernova, it will lie inside a radius $\sim 3 \times 10^9$ cm This material will be heated by the shock wave to temperatures $\sim 4 \times 10^9$ °K (ref 8) The energy density of radiation will then considerably exceed the thermal kinetic energy of the matter, and so the adiabatic expansion will be approximately characterized by a ratio of specific heats $\gamma = 4/3$

Early in the expansion, $kT/3 \gg \langle h\nu \rangle_{pg}$, so that the luminosity $L \propto T r^2$, where r is the radius of the envelope near optical depth unity We have $T \propto (\text{density})^{1/3} \propto r^{-1}$ Hence $L \propto r$ Later in the expansion, when $kT/3 \leqslant \langle h\nu \rangle_{pg}$, L becomes a sensitive function of T; at the least $L \propto T^4 r^2 \propto r^{-2}$ Hence it is evident that the maximum light emission occurs when $T \approx 10^4$ °K This will occur approximately for a radius $r \approx 3 \times 10^9\ (4 \times 10^9/10^4) = 1\ 2 \times 10^{15}$ cm Hence $L_{\max} \approx 4\pi r^2 \sigma T^4 \approx 10^{43}$ ergs/sec There is great uncertainty in this figure, but it is in order-of-magnitude agreement with the observed luminosity

PHYSICS

Current–Voltage Relations for Mobility-controlled Sheaths; a Simple Method for Determining Ion Mobility

Recently, the constriction of fairly high pressure discharges by applied radial electric fields has been observed by Kenty[1]. The discharges, which are very sensitive to electrostatic effects, are of the low current diffuse type in which the ions disappear mainly by volume recombination[2]. For d.c. fields, annular rings are provided just inside the wall of the tube. The discharge can be greatly constricted by making these rings negative to the discharge, while at the same time the positive ion current per unit length can be measured.

These observations can be understood in terms of the idea that when the wall is made highly negative a thick positive ion wall sheath is formed in which the current is due entirely to mobility flow. Since the thickness of the sheath can be measured quite easily by direct visual observations, and since almost all the applied voltage appears across the sheath, it has been suggested[1] that the constriction effect might be used to measure ion mobilities in a very simple way. It is readily shown that the relationship between the wall current, J, and the voltage across the sheath, ΔV, is of the form:

$$\Delta V = (J/\mu)^{1/2} g \qquad (1)$$

where μ is the mobility and g depends on the sheath thickness and the size and geometry of the discharge. Hence, knowing the sheath thickness, essentially all one needs to determine the mobility is an ammeter and a voltmeter. In this communication we derive equation (1) and calculate g for sheaths of cylindrical and spherical symmetry. For comparison, we also include the plane-parallel case, which has been treated by Cobine[3].

We assume that in the sheath: (1) only positive ions are present; (2) no production of ions occurs; (3) diffusion can be neglected; (4) the energy gained from the field in a mean free path is negligible compared with the thermal energy of the ions; (5) at the inner edge of the sheath, which is somewhat diffuse in practice, the field is approximately zero. Condition (2) will be fulfilled if photoelectric and secondary emission at the negative (sheath causing) electrode are small, and if the voltage across the sheath is well below that necessary for breakdown. The equations which describe the sheath are then:

$$\nabla^2 V = -4\pi q n \qquad (2)$$

$$\operatorname{div} j = 0 \qquad (3)$$

$$j = -nq\mu \operatorname{grad} V \qquad (4)$$

where V is the potential, n, the ion density, j, the current density, q, the ionic charge, and μ, the mobility. These equations do not, of course, provide a good description of the sheath in the low field region near the inner edge, since assumptions (1) and (3) are obviously not valid there. Since the field rises very rapidly, however, this region is quite small, and for thick sheaths the results are rather insensitive to the precise position chosen for the inner boundary.

We first eliminate n by making use of the fact that from equation (3) the net current across a surface of symmetry is constant. Denoting the plane-parallel, cylindrical and spherical cases, respectively, by an index $k = 0,1,2$, we write:

$$J_k = 4\pi\alpha_k r^k |j| \qquad (5)$$

where, for each symmetry, r is the appropriate co-ordinate and J_k is proportional to the appropriate wall current. It is convenient to take:

$$\alpha_0 = (4\pi)^{-1},\ \alpha_1 = 1/2,\ \alpha_2 = 1 \qquad (6)$$

so that J_0 is the wall current per unit area of the plane, J_1 is the wall current per unit length of the cylinder, and J_2 is the total wall current to the sphere. From equations (2) and (4), on making use of the fact that for the three geometries of interest $\nabla^2 V = r^{-k} \mathrm{d}/\mathrm{d}r(r^k \mathrm{d}V/\mathrm{d}r)$, we then have simply:

$$\mathrm{d}/\mathrm{d}r(r^k \mathrm{d}V/\mathrm{d}r)^2 = (2J_k/\alpha_k\mu) r^k \qquad (7)$$

Neglecting the field dependence of the mobility, this gives, for the field:

$$-\mathrm{d}V/\mathrm{d}r = [2J_k r_s^{1-k}/(k+1)\alpha_k\mu]^{1/2}[(r/r_s)^{1-k} - (r_s/r)^{2k}]^{1/2} \qquad (8)$$

and for the potential distribution:

$$V_s - V(r) = [2J_k r_s^{3-k}/(k+1)\alpha_k\mu]^{1/2} f_k(r/r_s) \qquad (9)$$

where the subscript s refers to values at the inner sheath edge, and:

$$f_k(z) = \int_1^z (t^{k+1} - 1)^{1/2}\, \mathrm{d}t/t^k \qquad (10)$$

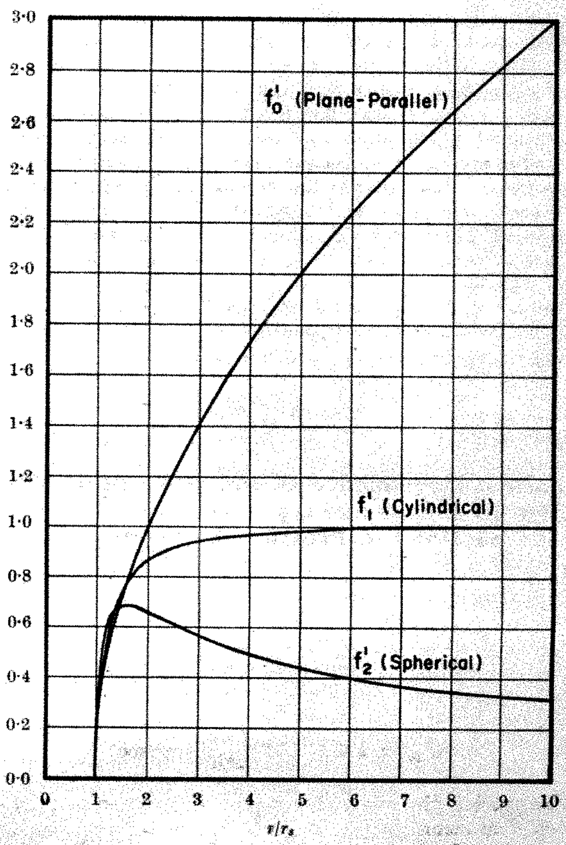

Fig. 1. Field variation in sheath

On setting $r = r_w$, the co-ordinate of the wall, equation (9) reduces to equation (1).

The integrals defining $f_k(z)$ are readily evaluated. We obtain:

Plane-parallel:

$$f_0(z) = (2/3)(z-1)^{3/2} \tag{11}$$

Cylindrical:

$$f_1(z) = (z^2-1)^{1/2} - \cos^{-1}(z^{-1}) \tag{12}$$

Spherical:

$$f_2(z) = z^{-1}(z - 1 + 3^{1/2})^{-1}(2z + 1 - 3^{1/2})(z^3 - 1)^{1/2} + (3^{3/4}/2)[(1 + 3^{1/2})F(\varphi, k) - 2\cdot3^{1/2}E(\varphi, k)] \tag{13}$$

where $F(\varphi, k)$ and $E(\varphi, k)$ are the incomplete elliptic integrals of the first and second kind, of modulus $k = \sin(\pi/12)$ and argument $\cos\varphi = (3^{1/2} - 1 + z)^{-1}(3^{1/2} + 1 - z)$. For small z equation (13) reduces to $f_2 \sim (2/3^{1/2})(z - 1)^{3/2}$, in agreement with the result for plane-parallel geometry. For large z it becomes:

$$f_2(z) \sim 2z^{1/2} - 3^{1/4}[(1 + 3^{1/2})K(k) - 2\cdot3^{1/2}E(k)] + 0(z^{-3/2}) \\ \cong 2z^{1/2} - 2\cdot24,\ z \geq 3 \tag{14}$$

This approximation is accurate to within about 5 per cent at $z = 3$ and improves with increasing z. For intermediate values of z, $f_2(z)$ is listed in Table 1.

Table 1. POTENTIAL DISTRIBUTION IN SPHERICAL SHEATH

z	$f_2(z)$	z	$f_2(z)$
1·1	0·0335	2·1	0·689
1·2	0·0877	2·2	0·754
1·3	0·150	2·3	0·818
1·4	0·216	2·4	0·880
1·5	0·284	2·5	0·942
1·6	0·353	2·6	1·003
1·7	0·422	2·7	1·063
1·8	0·490	2·8	1·121
1·9	0·557	2·9	1·179
2·0	0·624	3·0	1·236

The functions $f_k'(z)$ are plotted in Fig. 1, which indicates the small extent of the low field region, where the theory breaks down. The cylindrical case is of particular interest, because in this geometry the field is practically uniform across the entire sheath, so that the effect of neglecting the field dependence of the mobility is quite small.

The foregoing theory has been used, together with data on a cylindrical xenon discharge, to measure the mobility of xenon ions[1]. Agreement with published mobilities is satisfactory, indicating that the foregoing conditions 1–5 are sufficiently fulfilled.

Thermal Dependence of the Absorption Band Edge in Zincblende-type Cadmium Sulphide obtained in Pressure Experiments

THE discontinuity in the optical absorption edge shift of wurtzite-type cadmium sulphide (CdS–*W*) under a pressure of 27,000 kg/cm², reported in Edwards–Drickamer's experiments[1], was assumed as a phase transition, essentially complete at about 40,000 kg/cm², perhaps[2] due to the zincblende phase (CdS–*Z*). The high-pressure X-ray experiments recently carried out by Rooymans[3] in CdS–*W* under a pressure of 20,000 kg/cm² have shown indeed a rocksalt-type structure (CdS–*R*) with a lattice constant, measured under pressure, of a_0 = 5·30 Å and an X-ray density of 6·44 corresponding to $\Delta V/V = -25$ per cent during the transition CdS–*W*→CdS–*R*.

Spectroscopical observations carried out in our laboratory show that, after the removal of pressures, variable in range 25,000 kg/cm²–40,000 kg/cm², to which a set of CdS–*W* powder was subjected, the position of the absorption edge is always situated at a constant value of 5860 Å with respect to 5070 Å of the original CdS–*W*. According to a recent remark by Rooymans[4], the CdS–*W* after pressure treatment is mainly of the CdS–*Z* structure.

This communication aims at reporting the pressure-method used to prepare this unusual structural form of the CdS semiconductor and its fundamental optical properties, that is, the value of the optical activation energy and its thermal dependence estimated from measurements on optical absorption-edge. The CdS–*Z* structural form has been prepared as a definite and separate phase by pressing, under 40,000 kg/cm² at room-temperature, very fine powder of CdS–*W* into tablets, the press form being simultaneously evacuated. In pressing, uniform distribution of the material in press form received special attention. Samples, reddish in colour and glass-like after the first pressure treatment, became microcrystalline after a second treatment; the average crystal size increases after further pressure treatments of powdered material, and closely packed crystallites were visible under an ordinary microscope; the pyknometrical density of polycrystalline samples is found to be 4·10 g/cm³. The removal of the pressure, after the first treatment of CdS–*W* powder,

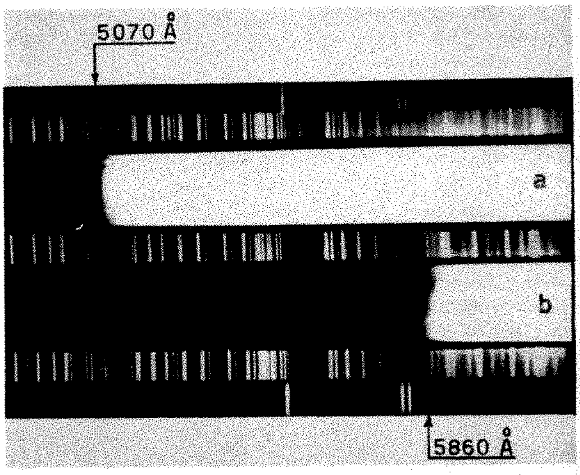

Fig. 1. Shift of the room-temperature absorption-band edge after CdS–*W* (*a*) to CdS–*Z* (*b*) pressure transition

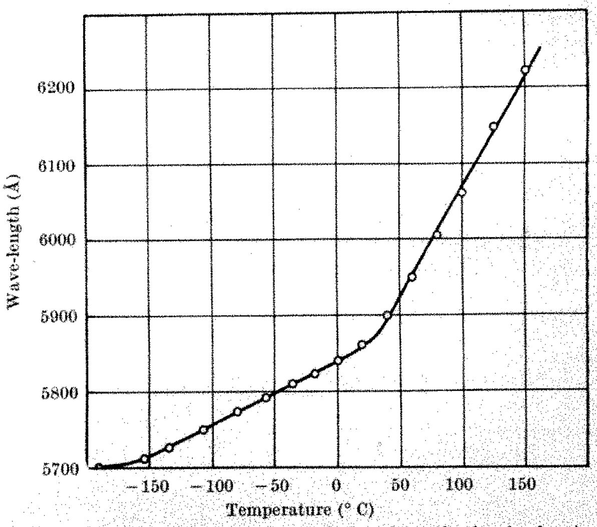

Fig. 2. Temperature dependence of the absorption-band edge in CdS–*Z* polycrystalline material

systematically causes the breakdown of the sample contained in a ring inside the press form; this is due to the increase in volume during the transition from the high-pressure CdS–R to the normal-pressure CdS–Z phases.

Comparatively, Fig. 1 shows the absorption spectra of CdS–W (*a*) and CdS–Z polycrystalline sample (*b*) carried out at room-temperature on the specimen, ground and polished to a thickness of 0·3 mm. From these measurements we obtain, for the CdS–Z polycrystalline sample, a value of 2·10 ± 0·01 eV at an absorption coefficient of $2{\cdot}5 \times 10^2$ cm^{-1}, in full agreement with the photoelectronic indication of a band gap of 2·1 eV recently reported by Lind and Bube[5] for cubic cadmium sulphide powder prepared by thermal decomposition of cadmium methyl mercaptide. According to our measurements, the CdS–Z form has an energy gap of 0·33 eV lower, at room-temperature, than CdS–W; this is an interesting fact since CdS–W and CdS–Z are, from the point of view of energy, quite similar. It should also be noted here that, for CdS–Z glassy specimens obtained after the first pressure treatment of CdS–W, the edge of the absorption band is situated at slightly longer wave-lengths compared with CdS–Z polycrystalline specimens. This edge shift, which corresponds to a decrease in the width of the forbidden band in CdS–Z glassy specimens, may be the result of a slight modification in the short-range order due to the glass formation[6,7].

Fig. 2 shows the plot of the absorption band edge as a function of temperature in the range from liquid air to 150° C; the wave-length of the edge is taken here as the point where the transmission is 0·5 per cent of its value in the non-absorbing region. $d\lambda_{\rm lim}/dT$ presents two slopes in the considered temperature range which corresponds to a shift of the band gap equal to $-3{\cdot}4 \times 10^{-4}$ eV/°C in the range $-150°$ C to 20° C, and to $-9{\cdot}4 \times 10^{-4}$ eV/°C between room-temperature and 150° C. We believe that the possibility of transforming the hexagonal form (CdS–W) into the cubic form (CdS–Z) with a physical process—that is, without changing the nature and the concentration of impurity atoms—offers a useful tool for studying the general properties of the CdS semiconductor depending on the long-range order, since the difference from CdS–W and CdS–Z is of geometrical order rather than of structural.

We thank Prof. G. Frongia for advice, and Dr. C. Muntoni for comments.

Anomalous Electron Scattering in Dilute Silver–Manganese Alloys and its Analogy with the Ramsauer Effect

DILUTE alloys of a transitional metal (for example, manganese) in a noble metal (for example, silver) exhibit anomalous properties at low temperatures. Their electrical resistivity in the neighbourhood of liquid hydrogen temperatures shows a minimum, followed by a maximum at a still lower temperature[1]. They exhibit a large negative (electrical as well as thermal) magneto-resistance[2,3]. Magnetic susceptibility measurements[4] suggest an antiferromagnetic transition with indications of 'parasitic' ferromagnetism as well.

The Lorenz parameter (in a zero magnetic field) shows anomalous behaviour[5] at liquid helium temperatures, 'dipping' below the normal Sommerfeld value L_n and tending to that value (L_n) at temperatures of about 1° K or below. This is probably because the pseudo-Weiss internal field arising from the transition to ferro/antiferromagnetism removes the spin degeneracy of the ground-state of the impurity (manganese) ion. The possibility of the manganese ion occupying either of two (or more) closely spaced levels makes it possible for the conduction electrons to undergo 'spin-flipping' inelastic collisions[6,7] with it, besides the normal elastic collisions. Since it is well known that inelastic small-angle scattering can, by virtue of electron transitions 'vertical' with respect to the Fermi surface, contribute considerably more to the thermal resistivity than to the electrical resistivity (while large-angle impurity scattering, even if inelastic, would, to quote Ziman[8] "merely turn a hot electron going east into a cold electron going west and thus has little effect on the heat current"), this mechanism seems to explain the dipping of the Lorenz parameter below the Sommerfeld value. The fact that, close to absolute zero, the Lorenz parameter approaches the value L_n is also understandable since such an inelastic scattering could not occur at absolute zero of temperature. Scattering which would involve loss of energy by the electron is not permitted since there are no lower electronic states available for it, scattering which would involve gain of energy by the electron is also not possible since there are no ions in the excited states at 0° K to transfer energy to the electron.

One would wonder whether, apart from this indirect evidence based on a dipping Lorenz parameter, there is any other evidence pointing to the possibility of the inelastic electron scattering taking place appreciably at small angles. Let us consider, for example, the anomalous scattering of slow electrons by rare gas atoms. Linde[9] has directed attention to the close similarity between the anomalous scattering of conduction electrons at low temperatures, due to magnetic impurities in noble metals and the anomalous scattering of electrons (having kinetic energies in the neighbourhood of the usual Fermi energies) by rare gas atoms, the so-called Ramsauer–Townsend effect[10].

Firstly, anomalous electrical resistivity behaviour is exhibited in a noble metal containing small amounts of metals like chromium and manganese which, in the gaseous state as well as in dilute solution[11], have an electron configuration rather similar to that of a rare gas.

Secondly, in the case of inelastic collisions of electrons with helium atoms, for example, it is found that, at small angles, inelastic scattering considerably exceeds the elastic scattering but drops below it at larger angles. If, in particular, the electrons are slow, electron exchange becomes significant and the experimentally observed[12] large scattering at small angles may be due to polarization effects caused by the interaction of the inelastic and the elastically scattered electron waves[13].

The anomalously high ('giant') thermo-electric power in these dilute alloys at low temperatures is thought to occur if, besides the asymmetry of the inelastic scattering about the Fermi energy of the solvent metal, two criteria are satisfied[14]: (1) the relaxation time for elastic scattering of the conduction electrons is spin-dependent; (2) there is appreciable, but not over-riding, inelastic scattering of the conduction electrons by the magnetic impurity ions.

The former criterion is also necessary to account for the negative (electrical as well as thermal) magneto-resistance, the magnitude of which correlates with the square of the magnetization of these alloys. But it is the latter criterion which is very significant in the present context: elastic scattering should also be present to a significant extent. In fact, the giant thermo-electric power is considered to be a consequence of 'mutual electron drag' arising from the interaction of the inelastic and the elastically scattered electrons, which again conforms to the explanation given[13] for the large small-angle scattering of electrons by the helium atoms

CRYSTALLOGRAPHY

Interdiffusion Method for the Preparation of Single Crystals of Certain Hydroxides and Basic Salts

Single crystals of insoluble compounds have been grown[1] by means of slow interdiffusion of solutions containing the constituent ions or molecules By making use of ammonia is one of two vertically interdiffusing solutions, I have grown single crystals, with dimensions ranging from a few tenths of a mm to a few mm, of the hydroxide, the basic nitrates and a basic sulphate, as well as the isomorphous basic selenate, of cadmium. Likewise single crystals of some of the corresponding compounds of divalent manganese and cobalt have been prepared

Cadmium hydroxide was made in the following way By means of a pipette, a 0 5 M solution of cadmium nitrate was carefully introduced at the bottom of a 200-ml beaker previously three-fourths filled with distilled water The beaker was placed in a desiccator together with a second beaker containing 3 M ammonia After a few days many crystals appeared in a ring-shaped zone about 1 cm wide at some intermediate level on the wall of the first beaker Thin hexagonal platelets formed in the upper part of the zone and large hexagonal prisms in the lower part Sometimes needle-shaped crystals of a basic nitrate appeared below the zone of hydroxide crystals By gradually increasing the initial concentration of the cadmium nitrate solution I obtained single crystals of two more basic nitrates

The other compounds already mentioned were obtained with the same or a slightly modified technique Some basic salts, for example, were best obtained when the first beaker was filled with a single homogeneous solution No systematic attempts were made to establish optimal growing conditions for any of the crystals

In contrast to most other diffusion methods, this process requires only a few days' time and can be carried out in a small beaker There is no need for taking rigorous precautions against shocks and vibrations, temperature fluctuations, etc It would seem that this is due to the use of ammonia, which is a weak base and which, furthermore, forms complex ions with the metal ions The complex formation causes an apparent increase in the solubility of the products This increase ultimately led to the dissolution of all crystals already formed if the process was not stopped in time

Hydroxides were obtained from solutions of the nitrates but not from other salt solutions For cadmium this may be traced to the fact that the concentration of the nitrate solution, which is in equilibrium with both the hydroxide and the basic salt, is relatively high[3].

I have determined the lattice parameters of all compounds obtained and the structures of some of them are being examined Although several of the basic salts seem to be new, others were obtained and examined before by Feitknecht[2,3] in his work on basic salts

This method may also apply to hydroxides and basic salts of such metals as lead, zinc, copper and certain trivalent metals

Superlattice Structure in Ga_2Te_3

Many $A^{III}{}_2B^{VI}{}_3$ compounds crystallize in structures based on zincblende or wurtzite Because of the unequal atomic concentrations of the components, some lattice sites which are occupied in zincblende and wurtzite are vacant in these compounds The original work on these compounds showed only crystal structures with a random distribution of the vacancies[1,2] Later, superlattice structures were observed for Ga_2S_3 (refs 3 and 4), In_2Te_3 (ref 5), and In_2Se_3 (ref 6) No superlattice for Ga_2Te_3 has previously been reported

In order to be able to observe a superlattice in Ga_2Te_3, it was decided to form the compound at as low a temperature as practicable Reference to the phase diagram[7] shows a compound $GaTe_3$, with a peritectic decomposition at 429° C. A mixture of 77·5 at per cent tellurium 22·5 at per cent gallium was heated to 450° C (at which temperature it is liquid) in a sealed, evacuated, silica tube The temperature at one end of the tube was then lowered by 5°–10° C for 5 days, and tellurium distilled off X-ray powder patterns from the residue were obtained in an 11 46 cm diameter Debye–Scherrer camera, using copper $K\alpha$-radiation

Seven lines were found which could not be indexed on the zincblende unit cell, containing 4/3 molecules of Ga_2Te_3 with random vacancies If one of these is ascribed to the strong line of tellurium, the remainder can be indexed on the basis of an orthorhombic unit cell, with the following lattice constants· $a=4\,1_7$ Å, $b=23\,6_0$ Å; $c=12\,5_2$ Å If the lattice constant of the zincblende cell is written as a_0, then these are related to a_0 as follows· $a=a_0/\sqrt{2}$ $b=4a_0$ $c=3a_0/\sqrt{2}$ By comparison with the zincblende cell, the orthorhombic unit cell contains 8 molecules of Ga_2Te_3 From the occurrence of a (070) reflexion, the space group must be primitive Assuming that the point group is a sub-group of $\bar{4}3m$ (the point group of zincblende) leaves 8 space groups, from which no further selection can be made

CHEMISTRY

Stability and Vaporization Behaviour of Group IV–VI Transition Metal Monophosphides

THE vaporization properties of Group IV–VI transition metal monophosphides were investigated in order to obtain knowledge of their thermodynamic stability and of the possible existence of binary gaseous molecules between phosphorus and the respective transition metal. For this purpose, a Knudsen effusion–mass spectrometer assembly similar to that described by Chupka and Inghram[1] was used. Included in the investigation were the monophosphides of titanium, zirconium, hafnium, niobium, tantalum, molybdenum and tungsten.

The primary phosphorus species observed in the vapour above the condensed phase were P, P_2 and P_4. In the temperature range 1,000° – c. 1,800° K, diatomic phosphorus was the major species. At higher temperatures monatomic phosphorus also became an important vapour component. Tetratomic phosphorus was, under all conditions, either a minor species or was not detectable. In no case has a gaseous species containing both metal and phosphorus been observed. This has been checked especially for the monomeric monophosphides. The concentration of such species in the vapour phase at the temperatures and pressures investigated is at least 100–1,000 times less than that of the major vapour species. With respect to the formation of binary gaseous molecules, the transition metal phosphides appear to behave similar to the corresponding nitrides for which no binary gaseous molecules have been observed.

All phosphides investigated vaporize according to equation (1) by decomposition into phosphorus vapour and a solid phase of lower phosphorus content:

$$\frac{z}{x} MP_{1-\delta} = \frac{z}{x} MP_{1-\delta-x} + P_z \qquad (1)$$

where $0 < x < 1-\delta$ and z is either 1, 2 or 4, δ is approximately 0.04 for TiP and NbP, and 0.08 for α-ZrP. For the other phosphides it is apparently close to zero.

From X-ray diffraction analysis of the residue, it was found that the condensed phase of lower phosphorus content, which is in equilibrium with the monophosphide, is phosphorus-saturated tungsten metal and sub-phosphides of the composition $MoP_{0.7}$ and $TiP_{0.6}$ in the respective systems.

Analysis of the phosphorus ion-intensity as a function of phosphorus content in the condensed phase at constant temperature indicates the presence of a homogeneity range for the TiP phase that extends between $TiP_{0.96-0.946}$ at 1,700° K. No indication for a homogeneity range was found for MoP, WP, and α-ZrP.

The ion-intensities of P_2^+ were correlated to vapour pressures through silver calibration[2]. The ratio in electron multiplier efficiencies for P_2^+/Ag^+ was 3.0. The ionization cross-sections for silver and monatomic phosphorus were obtained from Otvos and Stevenson[3]. For the phosphorus dimer the value of 21.8 was estimated. The possibility of a very low vaporization coefficient was not taken into account. The P_2-dissociation pressures obtained for the phosphorus-deficient boundary composition of the respective phosphide as a function of temperature were used for the calculation of the partial molal free enthalpies of phosphorus dissociation, $\Delta\bar{G}_T^\circ[P_2]$. The results are listed in Table 1 for 1,000° K, 1,500° K and 2,000° K. Also included is the temperature-range over which the experimental pressure measurements were made. For hafnium and tantalum monophosphides the determination of the temperature-pressure relationship was complicated by the apparent presence of a diffusion barrier, and, in the case of tantalum monophosphide, by reaction of phosphorus vapour with the tantalum effusion cell. From the possible observations it can be estimated that, at 2,000° K, the stability of tantalum monophosphide is comparable with that of α-ZrP and the stability of hafnium monophosphide is considerably higher than that of α-ZrP and similar to that of thorium subphosphide ($ThP_{0.7}$) (ref. 4) and uranium monophosphide[5]. The results presented in Table 1 show that the stability of the monophosphides of group IV increases markedly with atomic number. The same appears to be the case for the group V monophosphides of niobium and tantalum, while for molybdenum and tungsten monophosphides the stability trend is reversed. Within a period the stability decreases with atomic number. This decrease is most pronounced in third transition period.

Table 1. PARTIAL MOLAL FREE ENTHALPIES OF P_2-DISSOCIATION FOR SELECTED TRANSITION METAL MONOPHOSPHIDES

Compound	Temperature range of pressure measurement (° K)	$\Delta\bar{G}_T^\circ[P_2]$ in kcal/mole P_2 1,000° K	1,500° K	2,000° K
$TiP_{0.94}$	1,295–1,705	55.8	40.8	25.9
$ZrP_{0.92}$	1,770–2,120		66.8	51.1
$NbP_{0.95}$	1,200–1,450	55.4	34.0	12.7
MoP	1,190–1,450	54.3	28.3	
WP	950–1,250	36.7	17.3	

A comparison of the stability of the groups IV–VI transition metal monophosphides with the corresponding nitrides is attempted on the basis of information reviewed by Storms[6]. Such a comparison is only of relative significance for the groups IV and V compounds because of the strong dependence of the non-metal activity on the composition in a given binary system, and the difficulty of comparing compounds of exactly the same stoichiometry. For the groups IV and VI nitrides the family trends appear to be similar to those found for the corresponding phosphides, but are less pronounced. The trends within a period are also in the same direction as indicated for the phosphides, but are considerably more pronounced. As a result, the group IV nitrides, especially titanium nitride, are of higher stability than the corresponding phosphides; whereas the group V mononitrides appear to be somewhat less stable and the group VI mononitrides significantly less stable than the corresponding monophosphides. The high thermodynamic stability of hafnium monophosphide, α-zirconium monophosphide and tantalum monophosphide, together with their reported resistance to chemical attack, makes these compounds attractive for special high-temperature applications. The rather low stability of WP and the non-existence of a lower tungsten phosphide above 1,000° C make tungsten metal a promising oxygen-free container material for the more stable phosphides.

I thank the National Bureau of Standards for the use of the mass spectrometer. I also thank Dr. J. Efimenko for his help. This work was supported by the U.S. Atomic Energy Commission.

Molecular Orbital Theory and Experimentally Determined Energy-levels

ONE of the more successful descriptions of the electronic structure of aromatic hydrocarbons has been given by molecular orbital theory. Originally formulated by Hückel[1], it has been developed and modified by many different authors. An account of the molecular orbital theory in its various forms has been given by Daudel,

Moser and Lefebvre[2] There are two relationships given by molecular orbital theory which are of interest The first, concerning the ionization potential I of the molecule, is

$$I=\alpha+x_i\beta \qquad (1)$$

where α is the coulomb integral, β the exchange integral and x_i is a number characteristic of the molecule

The second is that the energy-levels ε_i of the ground-state molecule are symmetrical about α and have the form

$$\varepsilon_i=\alpha+x_i\beta \qquad (2)$$

The energy difference between the highest filled and lowest unfilled orbitals of the molecule is $2x_i\beta$ This figure has been taken to be the first singlet–singlet transition of the molecule[3,4] designated ^1L_a in Platt's notation[5], p in Clar's notation[6] In the simple molecular orbital theory, no account is taken of electron spin and the equating of $2x_i\beta$ to a term of definite spin multiplicity seems doubtful, and preferably one should take some averaged-out value over terms of different multiplicities Dewar[3] has suggested that as the lowest singlet–triplet transition ^3L_a is directly proportional to ^1L_a the use of ^1L_a alone is permissible A simple comparison of ^3L_a terms, designated T_1 in reference 7, with ^1L_a terms given in Table 2 shows that there is no direct relationship between ^1L_a and ^3L_a Values of β obtained by comparing $2x_i\beta$ with ^1L_a and other procedures are given in Table 1

Ionization potentials have been evaluated[4] by using an expression similar to equation (1), namely

$$I=a+b\nu \text{ (eV)} \qquad (3)$$

with $a=4\ 39$, $b=0\ 857$ and $\nu={}^1L_a$.

The value 4 39 is the work function of graphite[8], 'the infinite condensed ring molecule'. As the polycyclic aromatic hydrocarbons increase in size the ionization potentials decrease[7] and it is to be expected that as the molecule increases to infinity, the ionization potential decreases to 4 39 eV

An experimental correlation between the ionization potential and the first excited state E_1 has been found by Birks and Slifkin[7], namely,

$$I=4\ 39+1{\cdot}15\bar{E}_1 \text{ (eV)} \qquad (4)$$

where $\bar{E}_1$ in the original paper was put equal to $\dfrac{T_1+S_1}{2}$

T_1 is the ^3L_a level and S_1 is the ^1L_b (ref 5) or α (ref 6) level This equation holds for eighteen aromatic hydrocarbons to better than 0 05 eV Equation (4) is similar in form to the Huckel equations (1) and (3)

It is apparent that $\bar{E}_1$ or $1{\cdot}15\bar{E}_1$ is a better quantity to correlate with x_i or $x_i\beta$ than ^1L_a or any other state of definite spin multiplicity In Figs 1 and 2 are shown plots of x_i against ^1L_a and x_i against $1\ 15\bar{E}_1$ for 16 aromatic hydrocarbons The hydrocarbons benzene, triphenylene and coronene have not been included in this plot as, being highly symmetrical, their energy-levels, as predicted by molecular orbital theory, are degenerate[9] The best straight lines for the two graphs were calculated by the method of least squares[9,10], ^1L_a and $1\ 15\bar{E}_1$ being treated as the dependent variables The equation for the lines in Fig 1 is

$$^1L_a=5\ 27x_i+1{\cdot}13 \text{ (eV)} \qquad (5)$$

The sum of the squares of the deviations from this line is 0 2347 eV^2. Similar procedures have been applied by other authors to ^1L_a and x_i (refs 9 and 11) The equation for the line in Fig 2 is

$$1{\cdot}15\bar{E}_i=4\ 31x_i+1\ 07 \text{ (eV)} \qquad (6)$$

The sum of the squares of the deviations is 0 1272 eV^2 Hence x_i correlates better with $\bar{E}_1$ than with ^1L_a Equations (6) and (4) give

$$I=5\ 46+4{\cdot}31x_i \text{ (eV)} \qquad (7)$$

Thus Hedges and Matsen's[4] equation used to predict ionization potentials does not give correct results as, contrary to expectation, x_i and E_1 or ^1L_a do not approach zero together

The values of α and β obtained by comparing equation (7) with the Huckel equation (1) are 5 46 (eV) and 2 155 (eV) respectively One explanation for the high value of α is

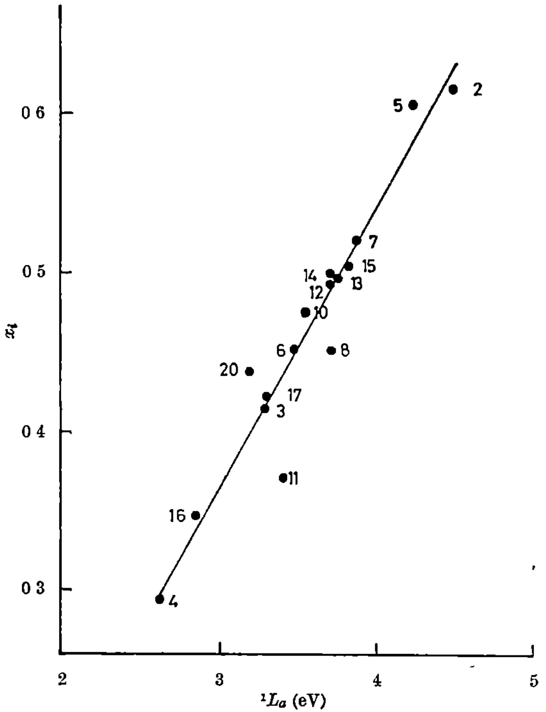

Fig 1 Plot of x_i against ^1L_a

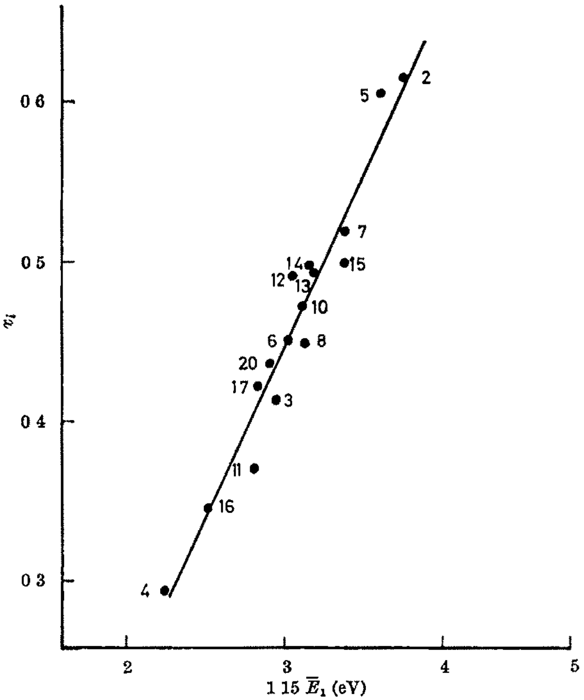

Fig 2 Plot of x_i against 1 15$\bar{E}_1$

that as the hydrocarbon molecules increase in size, the carbon–carbon separation increases[12] and hence α decreases This value of α is an averaged-out value for the relatively small hydrocarbons examined The low value of β obtained is due to the positive intercept on the x_i axis The value of β also increases as the carbon–carbon distance decreases, therefore this value of β should be regarded as an averaged-out value for the sixteen hydrocarbons examined

Another important energy-level of these molecules is the electron affinity E_A Molecular orbital theory[4] gives the relationship

$$E_A = \alpha - x_i\beta \tag{8}$$

By analogy with equation (4) we have

$$E_A = 4\ 39 - 1\ 15\bar{E}_1 \text{ (eV)} \tag{9a}$$

or

$$E_A = 8\ 78 - I \text{ (eV)} \tag{9b}$$

Values of the electron affinity derived in this way are listed in Table 2 No experimental values are available for comparison

Humidity and Photochemistry

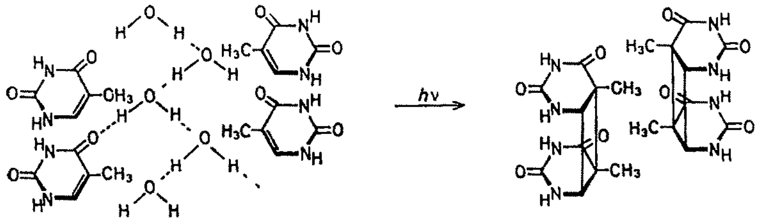
In the course of an investigation of the ultra-violet irradiation of solid films of uracil and thymine[1], certain inconsistencies were observed in the irradiation of thymine films which were unexplainable at the time and therefore not reported Information now available has led to an investigation of the influence of humidity, more properly the vapour pressure of water, on this photochemical reaction, and evidence is presented here that humidity is a factor in this reaction

When a thin film of solid thymine or uracil was irradiated, thymine-dimer or uracil-dimer was isolated[1] These dimers were found to be identical to those obtained when frozen solutions were irradiated[1,2] Thus, I proposed that microcrystalline aggregates of solutes form when solutions are frozen, and frozen solution irradiation may be used as an efficient method for irradiation of solid[1] Stewart has presented evidence to support this hypothesis and has pointed out that two thymine molecules held in a favourable configuration readily undergo the photochemical formation of the dimer[3]

Since thymine and uracil have absorbancy maxima in the 260–270 mμ region and the dimers of these compounds have no absorbancy in this region except for end absorption, the decrease in absorbancy was used as the criterion for dimerization It was found that irradiation of thin films of uracil resulted in a constant decrease of the absorbancy after irradiation However, the results varied in the case of thymine films, the greatest decrease in the absorbancy of the spectrum was 55 per cent, but most of the time it was less and in a few instances there was no decrease at all This inconsistency was difficult to understand at that time

The structure of thymine monohydrate crystal has now been determined, and the stability of the crystalline structure has been shown to be dependent on the water of crystallization When this water is removed, the framework of the crystal collapses[4] This information led to the suspicion that humidity may be the cause of the inconsistency in the results obtained for the irradiation of thymine films Thymine monohydrate crystals as described would be most stable at high humidities and would provide the ideal packing favourable for photo-dimerization, but on the removal of water, which would occur when humidity is lowered, the packing would collapse and dimerization would become difficult In order to test this possibility, irradiation of thymine films was carried out in a 'constant humidity chamber' A small desiccator was used for this purpose The opening of the lid was fitted with a two-hole rubber stopper through which was extended a thermometer (to permit a reading of the beaker temperature) and a model 11 *SC*–1 'Pen-Ray' quartz lamp (Ultra-violet Products, Inc , San Gabriel, California) The beaker containing the thymine film to be irradiated was elevated to a height in the desiccator so that the tips of the lamp and thermometer extended down into the beaker approximately one inch from the film A 100-ml beaker containing a constant humidity solution or phosphorus pentoxide was placed in the bottom of the desiccator and another small thermometer (to permit a reading of chamber temperature) was suspended to the side of this beaker through a rubber stopper fitted into the desiccator plate

The thin films were prepared in 50-ml beakers A 1 0-ml portion of a 1 mM methanolic solution of thymine was pipetted into the beaker, dried quickly on a heated hot plate, and placed in a constant humidity chamber overnight A reference absorption spectrum was recorded of a solution prepared by dissolving one of the films in 10 0 ml. of distilled water Additional films were irradiated for certain time intervals and absorption spectra were recorded of solutions prepared by dissolving each of the irradiated films in 10 0 ml of distilled water. The difference between the unirradiated and irradiated samples



indicates the percentage of dimerization. Table 1 shows the percentage of dimerization under various conditions

Table 1

Time (h)	Humidity (%)* 98	71	30	P_2O_5	Temperature (°C)* In beaker	In chamber
1	15 0	17 3	11 4	7 5		
2	31 0	30 9	21 0	16 3	40–44°	20–24°
3	55 5	55 0	27 0	21 7		

* The constant humidity solutions were prepared according to the *Handbook of Chemistry and Physics*, thirty-second ed (Chemical Rubber Publishing Co , Cleveland, Ohio, 1950), $CuSO_4$ $5H_2O$, 98 per cent, NH_4Br, 71 per cent, NaCl, 30 5 per cent Since humidity is related to temperature, both the temperature in the chamber and in the beaker containing the thymine film were noted

These results indicate clearly that as the humidity increases there is greater photodimerization. This suggests that the water content of the crystals is influenced by the surrounding humidity and that the hydrated form, favoured at high humidity, is the more easily dimerized form Based on this, it is suggested that humidity should be taken into consideration for an intermolecular photoreaction in crystals which contain water of crystallization

Photovoltaic Phenomena in Aqueous Solutions

RESULTS of our potentiometric measurements of the photovoltaic effect in the ultra-violet region on platinum and mercury electrodes in aqueous solutions of sulphuric acid, potassium hydroxide and potassium sulphate led us to the conclusion that the observed potential changes of the illuminated electrode are caused by a competitive action of oxidizing and reducing species formed in water under the incident light

A confirmation of this hypothesis has been found on examining the same solutions polarographically under constant irradiation by a high-pressure mercury lamp Whereas no observable change appears on polarographic curves of deaerated solutions of potassium hydroxide and potassium sulphate when exposed to light, a rapid increase of current of the magnitude about 10^{-8} amp (Fig 1) follows the illumination of the dropping mercury electrode in solutions of sulphuric acid On extinguishing the light, the current falls back to its original value The production of current on exposure to light begins to appear at potentials by about 0 6 V more positive than the rise of the reduction current due to electrolytic evolution of hydrogen, and it increases with increasing negative potential of the dropping electrode With increasing concentration of hydrogen ions up to about 1 N the current caused by light increases, further from there it begins to diminish In water–ethanolic solutions of sulphuric acid the photocurrent is smaller by about 1/2 than in aqueous solutions

Qualitatively the same phenomenon was observed with solutions of perchloric, hydrochloric and acetic acids Besides the appearance of this relatively small current on the foot of the wave the actual polarographic reduction wave of hydrogen ions is not affected by illumination. There was found no effect whatever of ultra-violet light on the foot of the polarographic reduction waves of oxygen, Cd^{4+}, Zn^{2+} or Ni^{2+} ions. Nitrous oxide dissolved under atmospheric pressure stimulates the increase of current in acid solutions and introduces an identical effect in solutions of potassium sulphate and potassium hydroxide

The described experimental results could be interpreted on the basis of the effect of the photosensitized decomposition of water on the electrode surface The metallic atoms in the surface of the electrode excited by the incident quanta of light transfer energy to the adsorbed molecules of water. It can be assumed that the dissociation products of water, H and OH radicals, are also adsorbed at the electrode surface, and that their heat of adsorption is greater than that of the water molecule In that case, quanta of lower energy than 118 kcal/mole (that is, light of longer wave-length than 2422 Å) can lead to splitting of the H–OH bond in water (The potential changes in all solutions and the production of photocurrent in acid solutions were observed to a small extent also with ultra-violet light of λ above 3200 Å.) The radicals formed recombine rapidly to water, molecular hydrogen or hydrogen peroxide The occurrence of the reaction products at the electrode surface results in a change of potential of the inert electrode, the extent and the direction of which depend on experimental conditions However, the concentration of the electroactive species is not high enough to cause a measurable polarographic current

In solutions of acids the hydrogen ions adsorbed at the negatively charged electrode combined with photolytically generated hydrogen atoms to form H_2^+ By this reaction the equilibrium between decomposition of water and recombination of its radicals is disturbed, and the total reaction now results partly in formation of H_2^+ and OH, which can both be reduced at the electrode in an extent sufficient to produce a polarographic current

A similar mechanism occurs in the presence of N_2O which turns hydrogen atoms into OH radicals Alcohol, on the other hand, acts as a scavenger of H and OH, changing

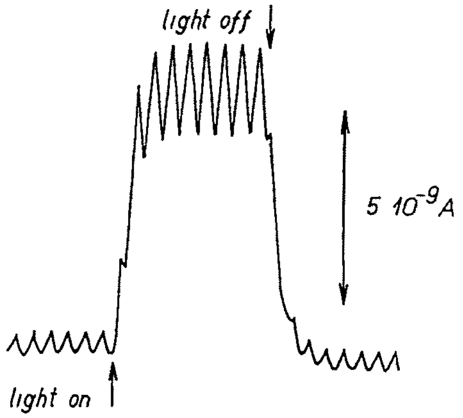

Fig 1 Polarographic current in deaerated 1 M H_2SO_4 at constant potential −0 9 V (versus 1 M Hg_2SO_4 electrode), illumination of the dropping electrode by an ultra-violet lamp denoted by arrows

them into water or molecular hydrogen, and thus suppresses to a certain extent the production of current

A photosensitized decomposition of water could well account for experimental results published by other authors on photovoltaic phenomena in aqueous solutions[1-3] as well as on the acceleration of electrodeposition of hydrogen and oxygen by ultra-violet light[4-6]

Effect of Geometrical Isomerism on the Behaviour of *cis* and *trans* Hexahydroindanes under Electron Impact

Recently[1] I reported observations on the behaviour of *cis* and *trans* decalines under electron impact It was shown that in these ionized stereoisomers an effect due to geometrical isomerism appears in two different ways First, mass spectra, although qualitatively identical, show important differences between relative abundances of several main fragment ions Relative abundances of molecular ions also differ and indicate a greater stability of ionized *trans* isomer Secondly, from the point of view of energetics two results were obtained (*a*) Ionization potentials measured for both isomers are the same, 9 61 ± 0 02 eV, within experimental uncertainties (*b*) Appearance potentials of the two fragment ions first produced indicate that a lower energy is required to dissociate ionized *cis* isomer into fragments

All these results can be interpreted in a satisfactory manner if it is noticed that the greater stability of ionized *trans* isomer parallels its greater thermodynamic stability which represents about 3 kcal/mole (ref 2) An amount of energy of that order due to steric conformation is released in *cis* decaline when fragmentation occurs

I wondered if a similar behaviour could still be observed in a case where the difference of thermodynamic stability between *cis* and *trans* isomers is smaller—the *cis* and *trans* hexahydroindanes (bi*cyclo*-0,3,4-nonanes) Thermodynamic stability of *cis* isomer is only 1 kcal/mole smaller than that of *trans* isomer[3]

Similar experiments were performed on hexahydroindanes as on decalines (*a*) Mass spectra were recorded for electron energies of a few volts above ionization potential, and relative abundances expressed as a fraction of total ionic current were calculated (*b*) Ionization potentials of both isomers were determined as well as appearance potentials of the two main fragment ions, that is, $C_7H_{12}^+$ and $C_6H_{10}^+$, mass numbers 96 and 82, which are formed in the simplest way as shown in the following scheme

$$\begin{array}{lcccccc} & \begin{array}{l}C_9H_{16}^+\\ m/e\ 124\end{array} & \rightarrow & \begin{array}{l}C_7H_{12}^+\\ m/e\ 96\end{array} & + & \begin{array}{l}C_2H_4\\ m/e\ 28\end{array} \\ \text{and} & & & & & \\ & \begin{array}{l}C_9H_{16}^+\\ m/e\ 124\end{array} & \rightarrow & \begin{array}{l}C_6H_{10}^+\\ m/e\ 82\end{array} & + & \begin{array}{l}C_3H_6\\ m/e\ 42\end{array} \end{array}$$

Appearance potentials of three other important fragment ions, $C_7H_{11}^+$, $C_6H_9^+$ and $C_5H_7^+$, absent in mass spectra at 10 volts but present at 12 volts, have also been determined

Relative abundances of ions are given in Table 1 for 12 and 10 volts electron energies

Table 1 Mass Spectra of *cis* and *trans* Hexahydroindanes at 12 and 10 V (Percentage of Total Ionic Current)

Ion formula	$C_9H_{16}^+$	$C_7H_{12}^+$	$C_7H_{11}^+$	$C_6H_{10}^+$	$C_6H_9^+$	$C_5H_8^+$	$C_5H_7^+$
Mass No	124	96	95	82	81	68	67
12 V							
cis isomer	19 9	31 3	2 3	26 1	8 5	1 0	2 5
trans isomer	28 5	26 3	3 3	22 3	3 7	1 3	6 1
10 V							
cis isomer	48 7	23 1	—	28 2	—	—	—
trans isomer	62 2	17 9	—	20 0	—	—	—

The figures in Table 1 show important differences between relative abundances of molecular ions and main fragment ions in *cis* and *trans* hexahydroindanes and indicate a greater stability of *trans* isomer as in the case of decalines

Table 2 gives results obtained for ionization potentials (*IP*) and appearance potentials (*AP*) in the two isomers under the same experimental conditions as for decalines Ionization efficiency curves have been treated by Warren's method[4]

Table 2 Ionization Potentials of *cis* and *trans* Hexahydroindanes and Appearance Potentials of Main Fragment Ions (eV)

Formula and mass No of the ion		*cis* isomer	*trans* isomer
$IP(C_9H_{16}^+)$	124	10 13 ± 0 03	10 18 ± 0 03
$AP(C_7H_{12}^+)$	96	10 96 ± 0 03	11 16 ± 0 03
$AP(C_7H_{11}^+)$	95	11 71 ± 0 05	11 80 ± 0 05
$AP(C_6H_{10}^+)$	82	10 79 ± 0 03	11 00 ± 0 02
$AP(C_6H_9^+)$	81	11 99 ± 0 05	12 07 ± 0 04
$AP(C_5H_7^+)$	67	12 21 ± 0 05	12 19 ± 0 03

From these results it turns out that, within experimental error, ionization potentials of *cis* and *trans* hexahydroindanes are the same On the other hand, appearance potentials of the two principal fragment ions, $C_7H_{11}^+$ and $C_6H_{10}^+$, are different, the values being smaller for the *cis* isomer than for the *trans* isomer For the other fragment ions investigated, no difference between appearance potentials could be detected

As a consequence, the behaviour of *cis* and *trans* hexahydroindanes under electron impact appears quite similar to that found in *cis* and *trans* decalines Although the difference between thermodynamic stabilities is very small in this case, only about 0 05 eV, there is a noticeable difference between the stabilities of ionized molecules as well as in the energetics of further decomposition of both isomers

The results recorded here can be interpreted in the following way (*a*) Relative thermodynamic stabilities are reflected in the behaviour of ionized isomers in the fundamental state (*b*) An amount of energy of 1 kcal/mole provided by steric conformation is released in *cis* isomer when the molecule breaks down into masses 96 and 82, and used in the breaking process itself

Similar cases of more complex systems are being investigated in this laboratory I thank Prof L D'Or and the Fonds National de la Recherche Scientifique for advice and support

Hydrolysis of the Phosphorothioate Ion catalysed by Silicone Grease

When preparing trisodium phosphorothioate from thiophosphoryl chloride and sodium hydroxide at 80° according to Åkerfeldt[1], it was observed that the yields became much smaller when the ground-glass joints of the apparatus used had been treated with silicone grease In fact, in some cases no trisodium phosphorothioate could be isolated from the reaction mixture In these instances liberal amounts of silicone grease had been used in lubricating the glass joints

Thus it was observed that silicone grease in some way interfered with the reaction between thiophosphoryl chloride and sodium hydroxide and/or caused a decomposition of the reaction product, the SPO_3^{3-} ion

A closer examination of this phenomenon has now revealed that silicone grease is a catalyst of the hydrolysis of the phosphorothioate ion in strongly alkaline solution

At 50° and in 1 M sodium hydroxide the rate of hydrolysis constant of the phosphorothioate ion was found to be $2\ 5 \times 10^{-4}$ min^{-1}, as measured in a carefully cleaned glass flask In the presence of 30 mg/100 ml of Dow Corning high vacuum silicone grease the rate of hydrolysis constant increased to $2\ 1 \times 10^{-3}$ min^{-1}, that is, nearly nine times the value obtained with a clean flask. The rates of hydrolysis were followed by determination of liberated orthophosphate according to Gomori[2]

It was further noticed that a strongly alkaline medium is necessary for silicone grease catalysed hydrolysis of the phosphorothioate ion No catalysis is observed, for example, at *p*H 8 0 This is probably due to the fact that in strongly alkaline medium silicone grease does no longer adhere to the walls of the glass flask, but is emulsified in the liquid, thus increasing the catalytic surface tremendously

Mechanistically the hydrolysis of the phosphorothioate ion in alkaline medium is likely to be due to a water attack on that ion[3]. The catalytic action of silicone grease may therefore involve activation of water molecules hydrogen bonded to the surface of the silicone grease. A similar water activation, caused by negatively charged oxygen atoms, is observed, for example, in the hydrolysis of certain S-substituted phosphorothioic acids[4].

Identification of Organic Compounds from Food Odours by Pyrolysis

IN preparing the combined technique of pyrolysis and gas chromatography for the general purpose of identification of compounds in food odours we now have carried out pyrolysis experiments using some aliphatic compounds as test substances In a previous note I reported the detection of the benzene ring in organic compounds by pyrolysis and gas chromatography[1], using a Pye apparatus from which the argon detector was removed and replaced by a flame ionization detector following the method of Murray and Williams[2] A column carrying 30 per cent 'Apiezon *L*' on 'Chromosorb *W*' was used The quartz pyrolysis tube (length, 20 cm , inner diam , 2 mm) was filled with 'Chromosorb *P*' over a length of 10 cm and was connected to the top of the column Nitrogen was used as the carrier gas at a flow of 32 ml /min

50–5,000 μg of the compound in the vapour form and in the presence of a large excess of air was injected through the pyrolysis tube, which was heated to 600° C by an electric furnace

The peaks of the pyrolysis products were characterized using the Kovats index scale, because this index has been shown to be nearly independent of experimental conditions[3]

The gas chromatograph thus was used as a "poor man's mass spectrometer", as first suggested by Keulemans[4]

Fig 1 illustrates the results obtained in the pyrolysis of some C_5 straight chain compounds with one functional group

It is seen that every compound shows a characteristic pyrolysis pattern The reproducibility of the pyrolysis patterns, obtained on repeated injections of the same compound, is good and eliminates the danger of misinterpretation of the results for identification purposes

For a tentative interpretation of these "pyrograms"[5] use was made of the relation between boiling point and Kovats index as reported elsewhere[3]

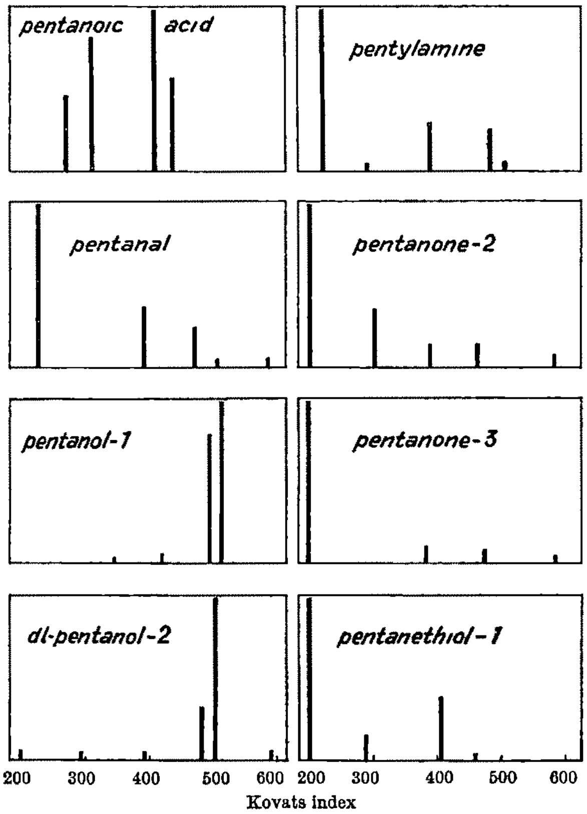

Fig 1 Results obtained in the pyrolysis of some C_5 straight chain compounds. Abscissa, Kovats index units Ordinate, relative peak area as percentage of main peak

The main reaction during the pyrolysis of the alcohol seems to be removal of water from the molecule with the formation of the corresponding olefine The pyrolysis of the acid results in the formation of a C_4-hydrocarbon by decarboxylation (main peak at 404 index units)

The carbon chain in the amine, aldehyde and the ketone is completely disintegrated into smaller fragments

Effect of Reaction of Urea with Jute on the Photochemical Degradation of the Fibre

IN the course of investigations carried out with the view of improving the resistance of jute fibre towards light by chemical modification, it was observed that a remarkable protection against degradation of the fibre by light can be achieved by reacting the fibre with urea in presence of a catalyst at an elevated temperature

Reaction of urea with cotton[1] has been shown to have no appreciable effect on the usual textile properties of the fibre In jute, however, marked changes in both physical and chemical properties of the fibre are noticed, particularly in the susceptibility of the fibre towards photochemical degradation Jute undergoes degradation under the influence of light at a much higher rate than other vegetable fibres[2] leading to loss in tensile strength, increase in alkali solubility and fibre acidity, and a number of other changes in fibre properties[3,4] Treatment with urea arrests these photochemical changes and this is illustrated by a set of experiments described here with results shown in Table 1

Table 1 EFFECT OF LIGHT ON UREA-TREATED JUTE YARN

Treatment	N_2 content (%)	Tensile strength (lb.)			Solubility in 1% NaOH			pH of aqueous extract (10%)		
		Before exposure	After exposure	Loss (%)	Before exposure (%)	After exposure (%)	Rise in solubility	Before exposure	After exposure	Decrease in pH value
Nil (original)	0.36	8.08 ± 0.21	6.03 ± 0.11	25.4	13.1	24.1	11.0	5.8	5.0	0.8
Blank (heated at 140° C)	—	7.99 ± 0.19	5.36 ± 0.19	32.9	13.1	24.3	11.2	5.4	5.0	0.4
Urea with catalyst	4.78	6.13 ± 0.14	5.94 ± 0.15	3.1	26.8	29.9	3.1	5.4	5.4	Nil
Urea without catalyst	2.54	6.18 ± 0.20	4.87 ± 0.20	21.2	20.2	29.5	9.3	5.6	5.2	0.4

The treatment[1] was carried out on de-oiled samples of 8.5-lb. broad loom warp yarn of average mill quality. The yarn was soaked in a 50 per cent (w/v) solution of urea containing 1.0 per cent cupric chloride as catalyst for 1 h, squeezed and air dried. A similar sample was also prepared without using the catalyst and the two samples, along with one untreated to serve as a blank, were placed in an air oven kept at 140° C. After 2 h heating at this temperature, the samples were separately washed with four changes of boiling distilled water for a period of 25 min and air dried. The three samples thus prepared were afterwards exposed in a fadeometer[5] along with a control, for 40 h. Tensile strength, solubility in 1 per cent sodium hydroxide and pH of aqueous extracts of the samples, both before and after light exposure, were then determined and the results given in Table 1.

The results show that under the conditions used for the reaction with urea, the nitrogen content of the fibre is raised from 0.36 per cent to 4.78 per cent and 2.54 per cent, the figures corresponding to the presence or absence of catalyst respectively, with a simultaneous lowering of tensile strength by about 25 per cent. After light exposure all the samples show appreciable reduction in tensile strength varying from 21 to 33 per cent except that treated with urea in presence of catalyst where the reduction in strength is only 3 per cent. Consistent results are also obtained in alkali solubility tests and the pH values of the aqueous extracts, which indicate that very little chemical changes have occurred during exposure of the fibre treated with urea in the presence of catalyst. Moreover, during alkali boiling of the light-exposed portions the resistant fibre did not show any lintering whereas the effect was well marked in all the other samples[6].

From the foregoing observations, it is evident that the photochemical degradation of jute is appreciably checked by reacting the fibre with urea in the presence of cupric chloride as a catalyst. In photochemical degradation of jute, the non-cellulosic components, particularly lignin, play an important part[5]. The reaction with urea probably modifies the lignin, either through cross-linking or otherwise, as a result of which the photo-sensitive property of lignin is minimized, leading ultimately to higher stability of the fibre in light.

BIOCHEMISTRY

Density Homogeneity and Estimated Molecular Weight of Interferon

THIS communication presents evidence of the density homogeneity of chick embryo interferon and gives an estimate of its molecular weight as determined by equilibrium sedimentation in a cæsium chloride density gradient.

The source of interferon was pooled allantoic fluids collected from 13-day-old chick embryos 3 days after infection with the *WS* strain of influenza *A* virus[1]. Crude interferon was prepared by centrifugation of allantoic fluid at 65,000*g* for 1 h and recentrifugation of the supernatant fluid at 100,000*g* for an additional hour. This procedure freed the allantoic fluid of all hæmagglutinin and most of the infectious virus. A similar crude interferon was concentrated and purified 10-fold (with respect to original protein concentration) by chromatographic separation on a 'Sephadex *G*-100' column[2]. Both the crude and partially purified preparations of interferon were used in this work.

Interferon was assayed by a modification of the plaque-inhibition method described by Wagner[1]. Monolayer cultures of chick embryo cells were exposed for 1 h to dilutions of crude or partially purified interferon or to fractions of these preparations collected after gradient centrifugation. The cell layers were then infected with an estimated 100 plaque-forming units of vesicular stomatitis virus and overlayered with nutrient agar containing neutral red. Quantitation of interferon activity was based on percentage reduction in number of plaques appearing during 44–48 h on interferon-treated monolayers compared with the number of plaques on simultaneously infected control monolayers. The interferon content of each fraction collected after gradient centrifugation was calculated from a dose-response curve determined concurrently for the unspun interferon.

Equilibrium sedimentation studies were performed as follows. 5-ml. samples of interferon were brought to a starting specific gravity of 1.31 by the addition of powdered cæsium chloride. The samples were centrifuged at 100,000*g* for 65 h in the swinging bucket rotor of a Spinco model *L* preparative ultracentrifuge. Approximately 60 fractions were then collected from the bottom of each centrifuge tube. After determination of its specific gravity, each fraction was dialysed against phosphate-buffered saline to remove cæsium chloride and afterwards assayed for interferon.

The results obtained with crude interferon, shown in Fig. 1, indicate that interferon activity banded at an apparent effective density of 1.30. The interferon appears to be homogeneous as evidenced from the Gaussian nature of its distribution about its effective density (Fig. 2). This graph was constructed by plotting the natural logarithm of the concentration of interferon against the square of the distance of each fraction from the region of maximum concentration of interferon. A Gaussian distribution, when so transformed, will be linear. The experimental results show a high degree of correlation to the linear regression line calculated by the method of least squares.

Meselson and Stahl[3] showed that the standard deviation of the distribution curve for a given macromolecular species in a linear density gradient is inversely proportional to the square root of the molecular weight of the macromolecule. The molecular weight may be calculated from the following equation:

$$\text{Mol. wt.} = \frac{\rho \; R \; T}{(d\rho/dr_0) \cdot \omega^2 \cdot r_0 \cdot \gamma^2}$$

where ρ is the effective density of the macromolecule, R is

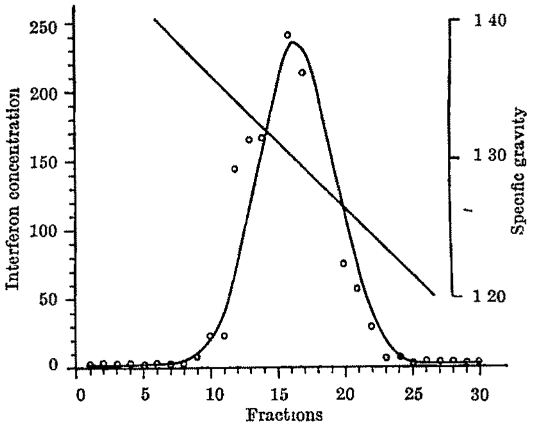

Fig 1 Distribution of interferon after equilibrium sedimentation of a crude preparation in a cæsium chloride density gradient The concentration of interferon in each fraction is represented by the open circles The density gradient is represented by the diagonal line

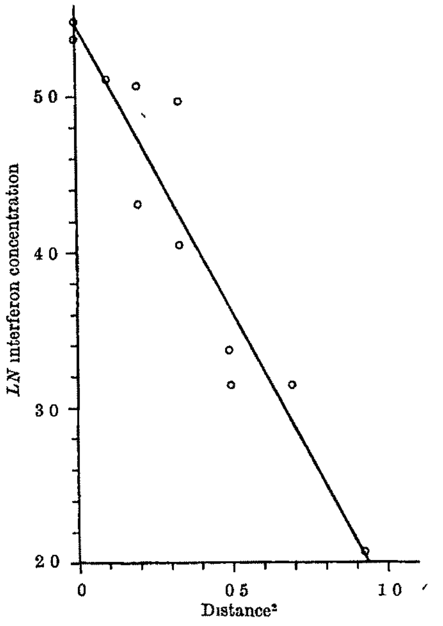

Fig 2 Evidence for density homogeneity of crude interferon The natural logarithm (*LN*) of interferon concentration is plotted on the ordinate against the square of the distance from the locus of maximum interferon concentration on the abscissa The regression line was calculated by the method of least squares

the gas constant, *T* is temperature (° Kelvin), $d\rho/dr_0$ is the slope of the density gradient, ω is the angular velocity, r_0 is the distance from the centre of rotation to the locus of effective density and γ is the standard deviation of the distribution curve of the macromolecule

Using this formula and substituting the experimentally determined value of ρ (1 30) and γ (0 45, the slope of the regression line in Fig 2), a molecular weight of 25,000 for interferon was calculated

Similar results were obtained by equilibrium sedimentation of a partially purified interferon (Fig 3) The effective density of this material was 1 31 and its distribution about its effective density also appeared to be Gaussian as evidenced from the linearity of its transformation (Fig 4) The molecular weight of this partially purified interferon was calculated to be 34,000

This range of values for the molecular weight of chick embryo interferon is in accord with values of 20,000–34,000 daltons determined by Lampson *et al*[4] from sedimentation velocity investigations of a purified interferon from a virtually identical source Purification of interferon is not required by the method described in this communication Furthermore, since each molecular weight calculation is determined by a large number of assay points, the error introduced by the relative lack of precision of interferon assay is minimized

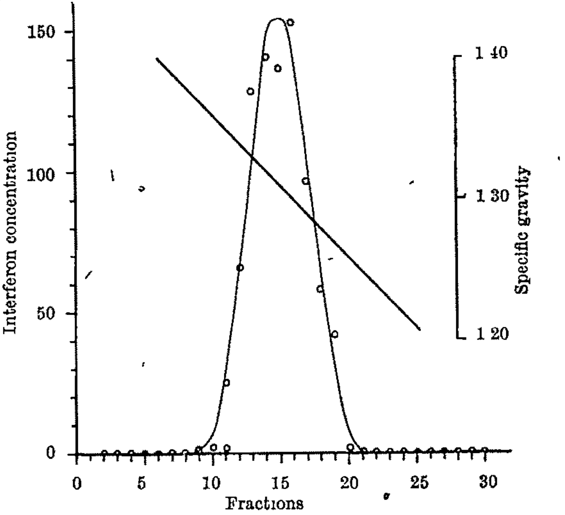

Fig 3 Distribution of interferon after equilibrium sedimentation of a partially purified preparation in cæsium chloride density gradient See legend of Fig 1

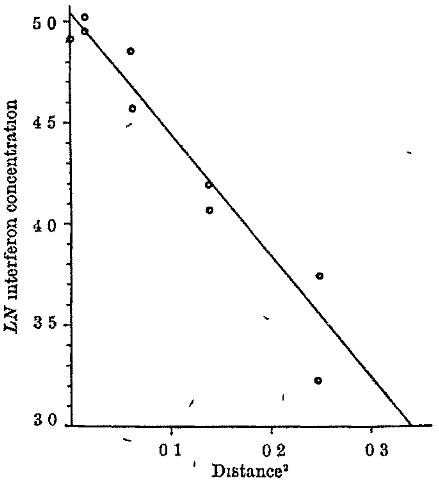

Fig 4 Evidence for density homogeneity of partially purified interferon The method of plotting is identical with that of Fig 2

This work was supported in part by research grant *AI*–05249–01, National Institutes of Health, U S Public Health Service, and by a Public Health Service research career programme award (*K*3–*GM*–10299)

Note added in proof Since this manuscript was submitted, Z Rotem and P A Charlwood (*Nature*, 198, 1066, 1963) have determined the molecular weight of chick, mouse and monkey interferons by sedimentation in sucrose density gradients, in conjunction with proteins of known sedimentation properties They concluded that the sedimentation coefficients of the three interferons were very close to that of lysozyme (1 9 S), and estimated a molecular weight range of 13,000–25,000 daltons

Origin of Methanol and Dimethyl Sulphide from Cooked Foods

A SURVEY of the volatiles produced from a range of cooked vegetables showed that both methanol and dimethyl sulphide were usually present as major components[1]. When a commercial sample of instant coffee powder was examined, however, no methanol and only small amounts of dimethyl sulphide were detected, although other common volatiles of low boiling point which are engendered from amino-acids[2] were conspicuously present. It appeared likely, therefore, that both methanol and dimethyl sulphide were produced from vegetables on cooking by some system which was not present in the coffee powder.

One obvious possible origin of methanol is pectin, which was suggested as the source in tea[3], although in this case it was believed to be produced by prior enzyme action (cf. ref. 4). We have now shown that when purified pectin preparations are boiled in phosphate buffer (5 mg/ml. 0·1 M, *p*H 6·5), they hydrolyse to yield methanol in comparable amounts as are formed from cooked vegetables. Methyl esters of simple carboxylic acids are not hydrolysed to any detectable extent under these conditions, and it appears probable that most of the methanol observed from cooked foods arises from the non-enzymatic hydrolysis of pectin.

Although dimethyl sulphide is known to be produced by heating a solution of methionine[2,5] either alone or in presence of sugars and other natural oxidants, the amounts formed are relatively small[2]. Obata and Mizutana[5], however, reported that heating methionine in the presence of plant material known to contain pectin increased the yield of the sulphide. We have now shown that heating methionine and purified pectin at 100° in buffer solutions (*p*H 6·5) at concentrations of 1–5 mg/ml. produces quantities of dimethyl sulphide together with dimethyl disulphide, methane thiol, acrolein and methanol, of the same order as obtained from certain cooked vegetables. It appeared likely that dimethyl sulphide is produced by a mechanism similar to that suggested by Lavine *et al.*[6] for the reaction of methionine with methanol in the presence of strong acids. However, the use of methanol alone, methanol and galacturonic acid, or methyl esters of simple carboxylic acids instead of pectin failed to increase the amount of dimethyl sulphide produced over that obtained from methionine alone. Methyl donors, such as choline and betaine, only showed trace activity. That pectin was acting as a methyl donor was shown by an examination of the decomposition of ethionine. When heated with ninhydrin[2,7] this compound gives mainly ethane thiol, but when pectin is present ethyl methyl sulphide is also produced. The influence of *p*H and other metabolites on the transmethylation reaction has still to be examined. It appears likely, however, that although dimethyl sulphide may be produced enzymatically[4] or from other sources[8], part at least comes from the reaction described, and this may be of importance in enhancing the flavour of manufactured foods.

Independence of the Formation of Extracellular Protease on the Amino-acid Level in the Cells of *Bacillus megatherium*

SYNTHESIS of extracellular protease in micro-organisms is repressed in the presence of free amino-acids in the medium[1-3]. However, the formation of intracellular enzyme is not influenced by amino-acids. The quantitative relationship between the amount of amino-acids present in the medium, their level in the cells and inhibition of enzyme formation was investigated during short-time incubation.

The culture grown up overnight on a solid synthetic *C*/*G*[4] medium was intensively aerated for 2 h in the same liquid medium at 35° C. The cells (0·75 mg dry wt./ml.) were washed and incubated at 35° C in the *C*/*G* medium containing different amounts of casamino-acids and calcium chloride (1 × 10⁻³ M) for the stabilization of the enzyme. After incubation for 1 h on a shaker (100 strokes/min, amplitude 6 cm) 100 μg/ml. of chloramphenicol was added. The proteolytic activity was determined in supernatant after centrifugation of the cells. No accumulation of the enzyme occurred in the cells during incubation with amino-acids. The free amino-acids were extracted from the washed cells by boiling for 20 min in the distilled water[6] and colorimetric determinations were carried out[7] (Fig. 1). In some experiments the centrifuged cells were not washed before boiling but the found amino-acid levels were almost identical.

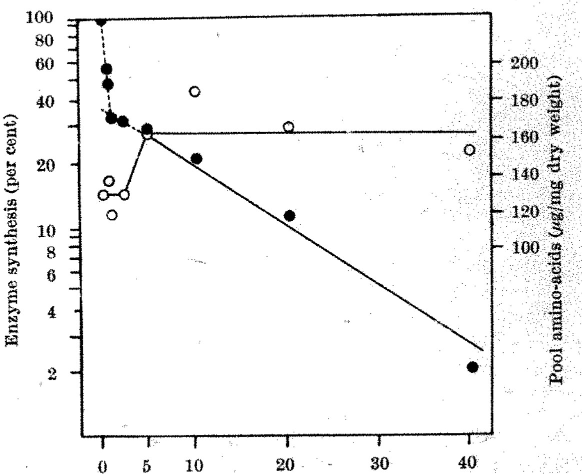

Fig. 1. Relationship between the content of amino-acids in the pool and protease repression. Growing culture of *B. megatherium* was incubated for 1 h on a shaker at 35° in synthetic medium (ref. 4) with Ca^{++} and the aforementioned concentration of casamino-acids. The formation of enzyme was stopped by addition of chloramphenicol

Chloramphenicol inhibited enzyme formation by 95–100 per cent; actinomycine *D* (2·5 μg/ml.) by 90–95 per cent. This shows that, under the conditions of these experiments, the enzyme was synthesized and not only released from the cells. The enzyme formation decreased logarithmically with the increasing amino-acid concentration in the medium. When the concentration of amino-acids was lower than 5 mg/ml., the repression approximated to 60 per cent. During incubation of the cells in the medium containing less than 1 mg casamino-acids/ml. the amino-acids were mostly consumed. The shape of the curve is, therefore, probably deformed in this region.

As is evident from the curve, there are two factors acting in the repression of protease formation by amino-acids, the nature of which is still unknown.

When the cells were incubated with 40 mg/ml. casamino-acids, enzyme formation was decreased by 98 per cent, but the amino-acid level in pool increased by 40 per cent only. When incubated with amino-acid concentration causing 70 per cent repression of protease, the content of free amino-acids in the cell was not increased at all. The hypothesis can therefore be suggested that amino-acids bring about protease repression only when entering the cell, probably during the transport through the cytoplasmic membrane. This suggestion corresponds with Gorini's[8] finding on repression of enzymes synthesizing arginine by exogenous arginine. Should this idea about the repression of synthesis of bacterial protease be confirmed, the concept on the role of cytoplasmic membrane in the control of cell metabolism will be supported[9].

It is possible to repress the protease formation in the synthetic medium by addition of individual amino-acids. Our preliminary experiments give evidence that, for example, threonine might play an important part in enzyme repression. In 1×10^{-3} M concentration it inhibits protease formation by about 70 per cent, but it has no influence either on the activity of the enzyme or on incorporation of ^{35}S-methionine into the cell proteins.

Changes in the Constitution of Myelin caused by Ions

IN an investigation of conditions which produce *in vitro* changes of myelin similar to those which occur in Wallerian degeneration (with formation of ovoids and spheres) the importance of the presence of a sufficient amount of calcium in the medium became apparent. A similar observation was made years ago by Nageotte[1]. The effects of high concentrations of calcium or of sodium ions on the constitution of myelin were therefore examined. Central and peripheral myelins homogenized with equal amounts of either 1 M sodium chloride or 0·5 M calcium chloride were extracted by water or by chloroform/methanol (2 : 1) and the extracts and residues were chemically analysed. Comparable experiments were performed by histochemical means on teased and cryostat-sectioned fresh central and peripheral nervous tissue.

It has been found that in the presence of excess sodium chloride in the medium an 'oil in water' emulsion is formed, in which the solubility characteristics of the droplets are determined by the polar ends of the phospholipids and proteins. In these circumstances, about 50 per cent of the cerebroside, of the phospholipids and of the cholesterol of myelin can be extracted by water together with a part of the myelin protein and mucopolysaccharide. Myelin homogenized with calcium chloride breaks down into a 'water in oil' emulsion in which the outer coat of the droplets is hydrophobic. Extraction of such an emulsion with water yielded some protein and polysaccharide and only small amounts of the various lipids. The difference between treatment with sodium chloride and treatment with calcium chloride is schematically demonstrated in Fig. 1. The effect of the ions is obviously due to the fact that calcium salts of phospholipids are more lipophilic, whereas the sodium compounds are more hydrophilic and therefore more attracted into the aqueous phase[2–4].

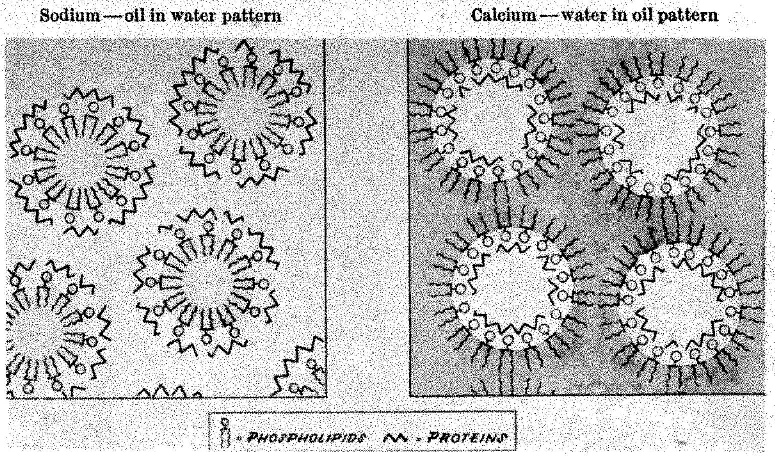

Fig. 1

Full results regarding these experiments, including findings which bear on the problem of the chemical morphology of myelin, will be published elsewhere. It is the purpose of the present communication to show the implications of these observations to a number of problems.

(1) The myelin sheath represents a cell membrane rolled on itself many times. It may be assumed that also *in vivo* ions and other factors capable of affecting the hydrophilia of polar lipids have a similar effect on the cell membrane and possibly also on membranes of various organelles to that which has been presently shown to occur *in vitro* in the myelin sheath. Bending of a phospholipid layer in the direction towards a 'water in oil' emulsion as shown in Fig. 2 (Ca) will produce an increased density of charges on the surface, an occurrence which might possibly be related to the phenomena of transmission of impulses. More marked bending over a large area of the membrane may help to explain phenomena associated with phagocytosis. A complete change of an area of a cell membrane into an 'oil in water' emulsion as shown in Fig. 3 (Na) will produce aqueous channels through which the cytoplasm communicates with the outside.

In an equilibrated area the lipid and aqueous layers are parallel and the inside of the cell does not communicate with the outside. Change into a 'water in oil' pattern (Fig. 3, Ca) will increase the impermeability to aqueous constituents, will render the wall more rigid and might allow lipid-soluble substances to cross the cell wall.

Recently, Luzzati and Husson[5] and Stoeckenius[6] have shown that emulsions of phospholipids in water assume under certain conditions a hexagonal pattern instead of

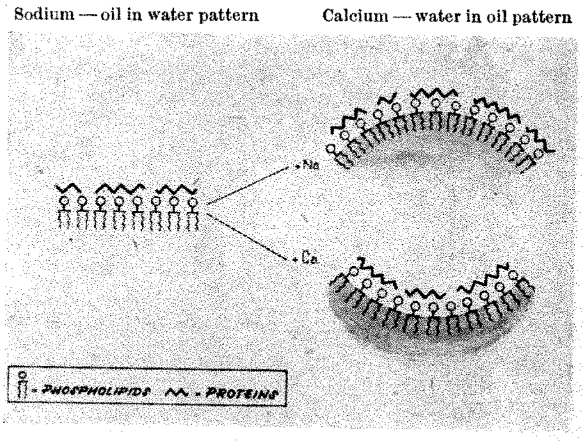

Fig. 2

the lamellar arrangement. A similar pattern was shown by Dourmashkin, Dougherty and Harris[7] and by Husson and Luzzati[8] to be present in the walls of various cells and viruses which underwent certain treatments. The hexagonal patterns described obviously represent 'water in oil' emulsion systems.

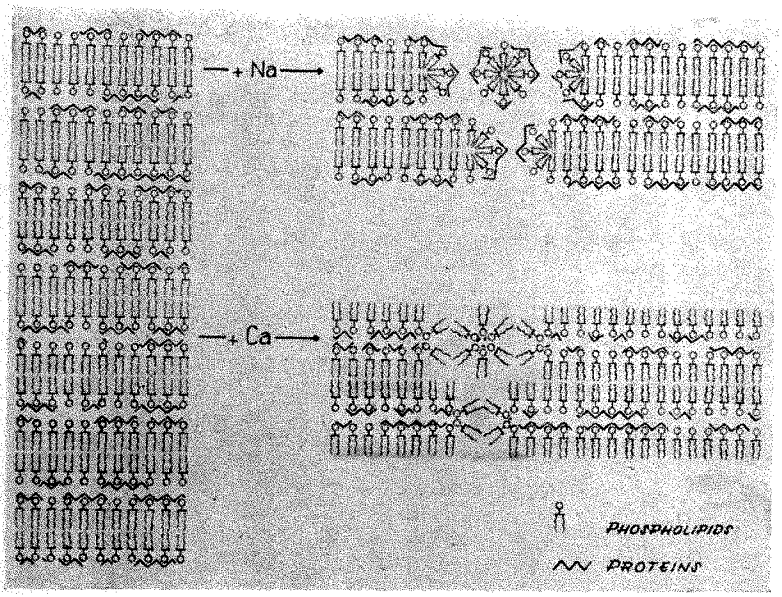

Fig. 3

(2) The lysosomes first described by De Duve are heterogeneous cellular organelles which behave like little bags which contain mainly hydrolytic enzymes with an acid *p*H optimum surrounded by a lipoproteic barrier which prevents free access of the respective substrates[9]. The lysosomes were considered to overlap in their characteristics mitochondria and microsomes[10]. It is suggested that the lysosomes and the 'smooth-surfaced vesicles' are derived from the endoplasmic reticulum, and possibly also from the mitochondria or even the cell membrane, by a change of these structures into 'water in oil' systems in which the membrane is folded into a globular body surrounded by polar lipids with the hydrophilic groups directed inwards. Enzymes which are normally situated on the outer surface of membranes and which belong, therefore, to the spaces between cells or between the two layers of internal reticulum, are enclosed in bags made by the inverted membranes. The enzymes may be regarded as belonging to the outer surface of cells and to spaces in continuity with this surface (to which the cavities between the layers of the endoplasmic reticulum and between the mitochondrial layers probably belong) which have been artefactually or *in vivo* enclosed in bags mainly lined by the polar groups of phospholipids.

Preparation of Phosphatidylserine

Several methods for the preparation[1,2] or quantitative isolation[3] of phosphatidylserine are now in existence. An investigation of some of the factors involved in the chromatography of phospholipids[4,5] revealed the role of H+ ion exchange in the conversion of the salt form to the acidic form of phosphatidylserine on a silicic acid column. The recognition of this phenomenon, which was also indicated by experimental results published afterwards[6], led to the development of a so-called silicic acid–'Hyflo Super Cel' column in the sodium form. These columns have been used successfully for the preparation of phosphatidylserine of high purity from ox-brain in conjunction with a shortened version of the method of Folch[7] for the isolation of phosphatidylserine-rich fractions.

The columns were prepared by treating a mixture of silicic acid (Mallinckrodt, *A.R.*, 100 mesh) and 'Hyflo Super Cel' in the proportion of 2 : 1 (w/w) with excess 1 N hydrochloric acid (vol. in ml. equivalent to approx. 15 times the weight of silicic acid) followed after filtration on a Buchner funnel by excess 1 M sodium bicarbonate in which the mixture was allowed to remain for 5 min. After filtration, the mixture was washed 5 times with distilled water which had been boiled until the *p*H had risen to 6·8. This is important since water which is slightly acid, for example *p*H 5·0, reconverts ionizable groups on the adsorbent from the Na+ form into the H+ form, resulting in the elution of some phosphatidylserine with cloroform/methanol 4 : 1 (v/v) together with phosphatidylethanolamine and other impurities. After having been washed, the mixture was spread in a shallow layer in an oven at 120° and left for 16–24 h. It was afterwards stored *in vacuo* over phosphorus pentoxide and used when required.

Ox-brain obtained freshly from the slaughter house and transported to the laboratory in ice was extracted with acetone, ethanol and petroleum ether (40°–60°) as described by Folch[7]. The latter extract was evaporated to dryness and the residue dissolved in a minimum volume of chloroform from which crude cephalin in a yield of 17 g/kg (wet wt.) of brain was precipitated with 5 vols. of ethanol (1 h at −10°). A phosphatidylserine-rich fraction (fraction III) was obtained from the crude cephalin by chloroform–methanol fractionation according to Folch[7]. The yield was 4·5 g fraction III/kg (wet wt.) of brain.

Columns were prepared from the treated silicic acid–'Hyflo Super Cel' mixture which had been washed with chloroform/methanol 4 : 1 (v/v) as described by Rathbone[6]. 58 g of the mixture gave a preparative column of suitable dimensions (26 cm × 2·3 cm) although smaller columns were frequently used. Fraction III was washed with 0·1 M sodium chloride and again with upper phase containing sodium chloride in the biphasic system of Folch, Lees and Sloane-Stanley[8]. The material derived from the lower phase was dissolved in a suitable volume of chloroform/methanol 4 : 1 (v/v) (approx. 3 mg P/ml.) and applied to the column at a loading of approx. 0·5 mg P/g of column filling. Chloroform/methanol 4 : 1 (v/v) (3·2 column volumes) eluted phosphatidylethanolamine, inositol phospholipids, cerebrosides and other impurities. Phosphatidylserine was eluted with chloroform/methanol 3 : 2 (v/v) (3·2 column volumes). The later fractions eluted with this solvent contained impurity. Thin-layer or paper chromatography of the fractions indicated those containing only phosphatidylserine, and these were pooled and the solvent was removed under reduced pressure in an atmosphere of nitrogen. The residue was dissolved in ether and centrifuged to remove particles and the lipid was finally stored in chloroform under nitrogen. The final yield of pure phosphatidylserine was approx. 3 g/kg wet wt. of brain.

Phosphatidylserine eluted from columns gave one spot staining with ninhydrin and protoporphyrin when chromatographed on silicic acid impregnated paper[9]. Traces of a ninhydrin-staining breakdown product appeared on storing, however, even at −10° under nitrogen. Chemical analysis of the phosphatidylserine was as follows: serine/P = 0·98; ethanolamine/P = 0·0; fatty acid/P = 2·01; absolute phosphorus content 3·82 per cent (theoretical 3·92 per cent). Determination of the fatty acids present by gas chromatography showed that oleic acid constituted 39·6 per cent of the total acids and stearic acid 52·4 per cent. C_{20} acids comprised 5·1 per cent and C_{16} acids 2·6 per cent. Since lysophosphatidylserine prepared by the action of snake venom phospholipase A on phosphatidylserine[10] contains mainly stearic acid and since phospholipase A removes the β-fatty acid of L-α-diacylglycerophosphatides[11,12], it is clear that a positional asymmetry of fatty acids exists in phosphatidylserine similar to that found in other phosphatides.

Comparison of *in vivo* and *in vitro* Actions of Various Ox Pituitary Growth Hormone Fractions

Discovery of an *in vitro* action of a hormone is of intrinsic value in determining the detailed mechanism of its action—a situation well illustrated in recent years in the case of insulin. Pituitary growth hormone is known to have an action *in vitro* on isolated muscle preparations—to stimulate uptake of glucose[1,2], incorporation of amino-acids into protein[3,4] and accumulation of a non-utilizable amino-acid[5] by diaphragm from the hypophysectomized rat, and to influence the metabolism of adipose tissue[6]. Whether these *in vitro* actions of the hormone play any part in bringing about its growth-promoting action has not been clarified[2,4,5,7-9]. The purpose of this communication is to show that by column chromatography ox growth hormone can be resolved into three fractions which, though all retaining potency *in vitro*, possess markedly differing growth-promoting activities.

Growth hormone, prepared by a modification of the Wilhelmi procedure[10] in which the initial extraction of the lobes is at *p*H 5·5, was chromatographed on columns of DEAE-cellulose (made by the method of Peterson and Sober[11]) in a borate buffer 6·5 mM $Na_2B_4O_7$ and 5·5 mM hydrochloric acid, *p*H 8·7. Part of the protein was eluted as a retarded peak in this buffer and the remainder with a sodium chloride gradient applied in two steps, the first increasing the molarity of sodium chloride to 0·1, the second to 0·5. Under these conditions, 80–90 per cent of the protein applied to the column was eluted as three main fractions: (*A*) eluted in the starting buffer (30–40 per cent); (*B*) eluted by the first gradient (15–25 per cent); (*C*) eluted by the second gradient (15–30 per cent). The proportion of each fraction varied with the original growth hormone preparation used, and in some cases evidence for heterogeneity within the fractions was suggested by the presence of more than one chromatographic peak. On rechromatography each fraction was eluted under the expected conditions. Examination of the starting material and the various fractions by starch-gel electrophoresis (using the method of Ferguson and Wallace[12], but with a slightly higher *p*H (8·8) at which all the main electrophoretic components move towards the anode) showed that chromatography had led to a separation of the electrophoretic components of growth hormone and that fractions *B* and *C* at least still contain several components. Fractions from two chromatographic runs were tested for growth-promoting activity in hypophysectomized rats, the increase in weight over 10 days of groups of five rats, each injected daily, being measured. The *A* fraction (Table 1) was found to possess growth-promoting activity similar to that of the unfractionated growth hormone. The faster running portion of the *B* fraction, though not quite so effective as *A*, also possessed growth-promoting activity, whereas B_2 and *C* fractions did not bring about any stimulation of growth when supplied at low doses. Injected in larger quantities B_2 showed about 10 per cent and *C* 3 per cent of the growth-promoting capacity of unfractionated growth hormone.

Table 1. Promotion of Growth of Hypophysectomized Rats by Various Fractions of Growth Hormone

Fraction	Dose (μg/day)	Increase in weight (mean ± *S.E.*) (g)	Increase in weight corrected for controls (mean ± *S.E.*) (g)
Saline control	—	−4·9 ± 0·9	—
Unfractionated	15	+10·3 ± 5·1	+15·2 ± 5·1
(1) *A*	15	+10·4 ± 3·7	+15·3 ± 3·8
(1) B_1*	15	+1·9 ± 1·7	+6·8 ± 1·9
(1) B_2*	15	−4·6 ± 2·0	+0·3 ± 2·2
(1) *C*	15	−0·9 ± 1·9	+4·0 ± 2·1
Saline control	—	+0·5 ± 0·7	—
Unfractionated	15	+10·8 ± 0·5	+10·3 ± 0·9
(2) *A*	15	+11·1 ± 1·8	+10·6 ± 1·9
(2) B_1	15	+9·7 ± 1·3	+9·2 ± 1·5
(2) *C*	15	+0·8 ± 1·8	−1·3 ± 1·9
Saline control	—	−2·2 ± 0·7	—
Unfractionated	5	+5·9 ± 0·9	+8·1 ± 1·2
Unfractionated	15	+10·5 ± 2·2	+12·7 ± 2·3
Unfractionated	45	+17·6 ± 1·5	+19·8 ± 1·7
(1) B_2*	150	+11·7 ± 2·0	+13·9 ± 2·2
(2) *C*	150	+4·9 ± 1·3	+7·1 ± 1·5

*Fraction (1) *B* showed some separation into two peaks and these were tested separately.

Uptake of glucose by diaphragm was measured by the disappearance of glucose from the medium[13], incorporation of glycine into protein as previously described[14] and release of free fatty acids from the epididymal fat pad was estimated by Dole's method[15]. Each fraction of a third chromatographic run was found at a concentration of 50 μg/ml. to stimulate uptake of glucose and incorporation of glycine into protein of diaphragm from the hypophysectomized rat (Table 2). A similar effect was seen when the concentration was reduced to 5 μg/ml. Moreover, the fractions tested in Table 1 and found to possess little growth-promoting activity were found at 1 μg/ml. to stimulate uptake of glucose and in two cases amino-acid incorporation (Table 2). A significant *in vitro* action of *A* at 0·1 μg/ml. was not observed. Each of these fractions at 25 μg/ml. was found to stimulate release of fatty acids by fat pads from normal rats (Table 3).

Thus the *in vitro* activity of fractions B_2 and *C* appears to be more or less as great as for *A* and B_1 (much more than 20 per cent, Table 2) despite their growth-promoting activity being very substantially less (much less than 10 per cent in the case of *C*, Table 1). On the other hand, the retention of *in vitro* activity by fractions *A* and B_1

Table 2. EFFECT OF VARIOUS FRACTIONS OF OX PITUITARY GROWTH HORMONE ON THE UPTAKE OF GLUCOSE AND INCORPORATION OF GLYCINE INTO PROTEIN BY ISOLATED DIAPHRAGM FROM HYPOPHYSECTOMIZED RATS

Fraction added to incubation medium	Uptake of glucose (mg/g wet wt./h)	Radioactivity in protein (c.p.m./mg)
No addition	3·17±0·13	16·4±0·35
(3) *A* (50 μg/ml.)	4·95±0·31	21·9±1·3
(3) *B* ,,	5·20±0·64	22·8±2·6
(3) *C* ,,	5·50±0·58	21·4±2·0

(1) B_2 (1μg/ml.)	4·28±0·27	14·1±1·00
(1) *C* ,,	3·31±0·12	11·0±0·66*
(2) *C* ,,	3·39±0·15	12·7±0·42
No addition	2·47±0·29	11·3±0·44
(3) *A* (0·1 μg/ml.)	3·08±0·58*	10·9±0·82*
(3) *A* (1 μg/ml.)	4·40±0·41	15·0±1·43

Each figure is the mean ± *S.E.* of the mean of six observations. Except for (*) the value of *P* for the stimulation due to each fraction is at least <0·05. Incubation was for 1·5 h, initial concentration of glucose was 2·5 mg/ml.

Table 3. EFFECT OF VARIOUS FRACTIONS OF OX PITUITARY GROWTH HORMONE ON THE RELEASE OF UNESTERIFIED FATTY ACIDS BY EPIDIDYMAL FAT PADS OF NORMAL RATS

Fraction added to incubation medium	Fatty acids released (μmole/g tissue/3 h)
No addition	5·2±0·51
(3) *A* (25 μg/ml.)	12·4±1·00
(3) *B* ,,	10·0±0·81
(3) *C* ,,	11·5±1·20

Each figure is the mean ±*S.E.* of the mean of six observations. The value of *P* for the stimulation due to each fraction was <0·001. Incubation was for 3 h in a medium containing 5 per cent ox serum albumin.

which also possess good growth-promoting activity does not provide any evidence of the possibility of a separation of the agents responsible for the *in vivo* and *in vitro* actions[8,15,16], though it is not completely excluded. Although the *in vitro* actions of growth hormone remain a fascinating problem in mechanism it is doubtful whether at the present time they provide a very helpful guide to the means by which growth hormone promotes growth.

We thank Miss M. B. Thomas for the hypophysectomies and Prof. F. G. Young and Dr. H. B. F. Dixon for their help and advice.

Control of Cellular Differentiation in Plants by the Distribution of Enzymes in a Lipid-bound System

IN analysis of the sequence of enzyme differentiation it was found that several enzymes are lipid-bound and that tissue differentiation is determined by the distribution of enzymes in a lipid-bound system. During an investigation of unsaturated lipids and the hæmatin enzymes in the endodermis and phloem of plants it was found that there is a functional relation between unsaturated lipids and the enzymes which determine differentiation and development[1]. Lipotropic agents applied to growing plants changed the pattern of enzyme distribution with resultant changes in tissue differentiation. Ethylene, in concentrations ranging from saturation in water to only a few parts per million, induced changes in lipoprotein. Associated with these changes it was found that the location of the lipids, and associated enzymes that give rise to the endodermis, were changed from normal distribution to new locations.

Ethylene at high concentrations induced a change in unsaturated lipid material in the endodermis and phloem, and negative reactions were obtained for cytochrome oxidase, peroxidase, and some dehydrogenases and esterases. Leaves of narcissus bulbs grown in an ethylene atmosphere had a redistribution of sudanophilic and osmophilic lipids. Lipid materials either moved to or were induced to form in the outermost cells of the leaf under the lower epidermis; and there was an associated change in the distribution of enzymes, particularly the hæmatin enzymes. A redistribution of lipids and enzymes to one side of the leaf appeared to be responsible for the asymmetrical growth associated with ethylene.

By growing plants in lipotropic substances (ethylene, etherized water) the endodermis and hypodermis, notable for their localizations of unsaturated fatty acids and peroxidase[2], were blocked in their normal topographic development. Under ethylene, the lipid–hæm systems that normally impregnate the walls of the endodermis are deposited elsewhere and apparently move outward to the surface of the plant. In roots and stems of castor beans, changes in enzyme pattern and tissue differentiation occurred in the endodermis adjacent to phloem; the endodermis between the vascular bundles contained some unsaturated lipids and associated peroxidase and cytochrome oxidase.

Lipid-bound enzymes of the phloem are apparently in the mitochondria of the sieve tubes and companion cells, but there appears to be a lipid–hæm peroxidase system free in the sieve tubes and not localized in mitochondria. It has been postulated that phospholipids hold functional groups of enzymes[3]; unsaturated lipids apparently hold in close association groups of enzymes that determine the differentiation and location of the endodermis in plants.

The general effect of ethylene and etherized water on plant tissues has been observed[4-7] and an interpretation is now presented of the influence of ethylene on the distribution of lipids, lipid-bound enzymes and resultant tissue differentiation. The breaking of cambial and bud dormancy by ethylene has been supposed to affect the concentration and distribution of auxin; but detection of unsaturated lipids, and microtitration to determine iodine numbers, reveal changes in distribution of unsaturated lipids. Ethylene must be applied prior to the appearance of lipid carbonyl compounds and in advance of normal lipid condensation and polymerization in protoplasts, walls and cellular membranes. The heat-stable lipid-bound peroxidase system of the endodermis may be changed in its differentiation if ethylene is applied in the formative stages of tissue development.

Human Red-cell Phosphogluconate Dehydrogenases

SINCE the advent of starch-gel electrophoresis various enzymes, including serum cholinesterase[1], erythrocyte glucose-6-phosphate dehydrogenase[2] and erythrocyte acid phosphatase[3], have been demonstrated to exist in human beings in different genetically determined modifications. We report here a procedure for the detection of human red-cell 6-phosphogluconate dehydrogenase (6-PGD) by starch-gel electrophoresis, and the existence of this enzyme in different genetically determined forms.

Blood (0·2 ml.) is added to water (0·4 ml.) and after 10 min the mixture is spun at 2,000*g* for another 10 min. Clear hæmolysate (50 µl.) is applied to each 12 mm × 4 mm insert of Whatman No. 17 filter paper. Electrophoresis[4] is carried out for 4 h at a potential gradient of 10 V/cm in a starch-gel, made in 0·01 M phosphate buffer at *p*H 7·0, and placed horizontally between two cooling plates. 6-PGD activity is detected by a modification of a method described for glucose-6-phosphate dehydrogenase[5]. An 'overlay', made up in 10 ml. of 0·1 M *tris* buffer at *p*H 8·0 containing agar (100 mg), nicotinamide adenine dinucleotide phosphate (2·0 mg), sodium-6-phosphogluconate (10 mg), phenazine methosulphate (0·4 mg) and the tetrazolium salt 'MTT' (2·0 mg), is poured at 45° over the sliced starch-gel and after setting is incubated at 37° for about an hour. The enzyme is located as a bright blue zone.

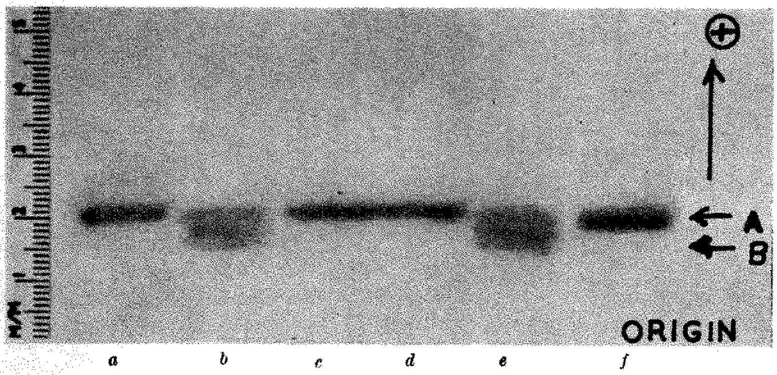

Fig. 1. Starch-gel electrophoresis of 6-PGD in human hæmolysates in 0·01 *M* phosphate buffer at *p*H 7·0

The normal result for red-cell 6-PGD is shown in Fig. 1, *a*, *c*, *d* and *f*, and consists of a single sharply defined band, *A*, which moves about 2·0 cm towards the anode. In 10 instances out of 150 random blood samples from adults, mostly of European descent, we detected the atypical band pattern shown in Fig. 1, *b* and *e*, where the sharp band *A*, although still present, stained to about half the intensity of the normals, and was accompanied by an equally sharp band *B*, which ran somewhat more slowly, and which likewise stained with about half the intensity of the normal *A* band. When bloods showing this variant 6-PGD were examined at intervals over a period of several weeks they were always found to have the same electrophoretic pattern, indicating that the possession of these two bands is a constant characteristic of the red cells of such individuals.

The presence of heparin in concentrations necessary to prevent clotting interfered with the normal electrophoretic behaviour of 6-PGD, but if the red cells were washed before hæmolysis this 'heparin effect' disappeared.

Examination of the families of several of the variant individuals demonstrated that the trait is genetically determined and is probably a heterozygous condition for a gene pair, with simple Mendelian inheritance of an autosomal nature. One such pedigree is shown in Fig. 2. With an incidence of about 1 in 15 one would expect that 1 person in $30^2 = 900$ would be homozygous for the atypical variety of 6-PGD. So far we have not found such an individual.

The total red-cell 6-PGD activity was determined quantitatively[6] in several cases for the heterozygous condition and was found not to differ significantly from the

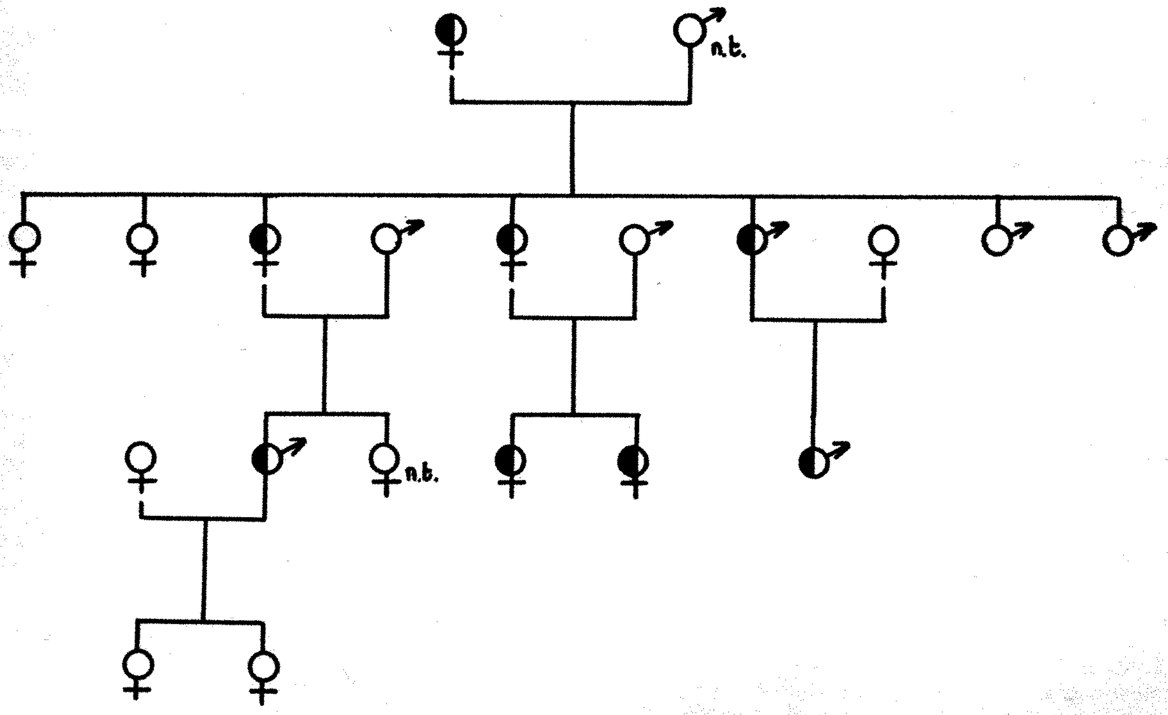

Fig. 2. Pedigree of a family in which the 6-PGD variant occurs. ◐, *A* plus *B* bands; ○, *A* band only; *n.t.*, not tested

total activity in individuals with the normal homozygous state.

Identification of *p*-Hydroxyphenoxymethyl Penicillin as a Metabolite of Phenoxymethyl Penicillin

When urine of normal adults to whom phenoxymethyl penicillin (penicillin V (200 mg)) had been administered was chromatographed[1], a second inhibition zone in addition to the penicillin V zone was observed (Fig. 1). The R_F value of this product was identical with that of *p*-hydroxyphenoxymethyl penicillin, obtained from a sample of crude penicillin V[2]. This metabolite represents about 10 per cent of the activity found in the urine.

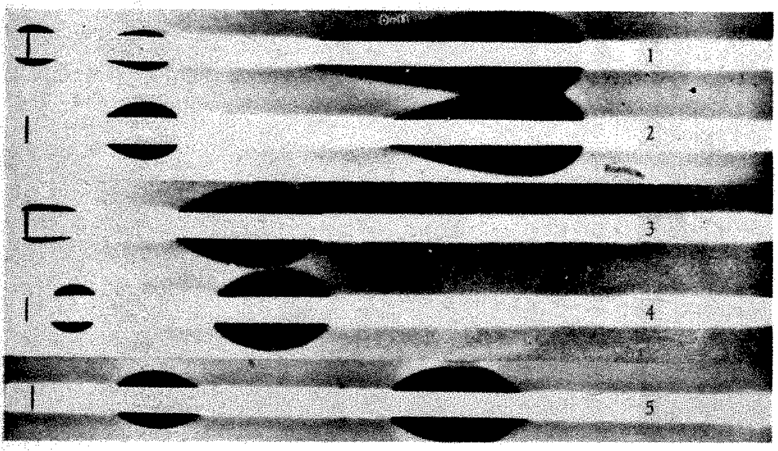

Fig. 1. Bioautography of paper chromatograms of urine after oral administration of penicillin V and phenethicillin. Whatman No. 1 paper, buffered with 10 per cent sodium citrate at *p*H 5·5 (Nos. 1 and 2) or *p*H 6·0 (Nos. 3, 4, 5). Developing solvent: ether saturated with 28 per cent ammonium sulphate. R_F values of penicillin V: 0·60 ± 0·06 at *p*H 5·5 (Nos. 1 and 2), 0·32 ± 0·04 at *p*H 6·0 (Nos. 3 and 4); *p*-hydroxypenicillin V: 0·13 ± 0·02 at *p*H 5·5 (Nos. 1 and 2), 0·05 ± 0·01 at *p*H 6·0 (Nos. 3 and 4); phenethicillin: 0·49 ± 0·05 and metabolite: 0·17 ± 0·02 at *p*H 6·0 (No. 5)

To confirm the structure of this substance, pooled urine samples were extracted with butyl acetate, after acidification to *p*H 2·0 with phosphoric acid. The penicillin was extracted from the organic solvent into bicarbonate solution and re-extracted into ether after acidification. The ether solution was applied on a column of silica gel, equilibrated with 2 M phosphate buffer of *p*H 6·2. The column was developed with ether containing increasing amounts of methanol (0·5–3 per cent), as described by Behrens *et al.*[3]. The column was cut into 1-in. sections, which were eluted with phosphate buffer of *p*H 7·0. The top section contained the metabolite and some penicillin V. The product eluted from the top of the column was hydrolysed by refluxing in 3 N hydrochloric acid for 24 h, and the side-chain acid was extracted with ether. By circular chromatography using system *E* of Högström[4], phenoxyacetic and *p*-hydroxyphenoxyacetic acid could be identified. There was also an indication of the presence of the *ortho*-acid on the paper chromatogram (Table 1).

Further confirmation of the structure of the side-chain acid was obtained by gas chromatography of the methyl esters. The acid was treated with methyliodide (7 m.mole) and 0·5 M sodium methylate (2 m.mole) for 5 h at 65° in a sealed tube. In this way phenoxyacetic acid was transformed into the methyl ester, and the hydroxyphenoxyacetic acid into the methyl ester of the methoxy acid. These esters could be separated by gas chromatography on a column of 'Reoplex 400' (20 per cent) at 180° (ref. 8). By this method the presence of *p*-hydroxyphenoxyacetic acid was confirmed, and a small peak of *o*-hydroxyphenoxyacetic acid was detected.

Table 1. Paper Chromatography of Phenoxyacetic Acids

Acid*	R_F†	Colour‡
o-$HOC_6H_4OCH_2COOH$	0·41	Violet
m-$HOC_6H_4OCH_2COOH$	0·23	Red-violet
p-$HOC_6H_4OCH_2COOH$	0·15	Blue
$C_6H_5OCH_2COOH$	0·37	—

* The hydroxyphenoxyacetic acids were prepared by reaction of the appropriate dihydric phenol with chloroacetic acid[5,6].

† Butanone-2 : water : diethylamine, 921 : 77 : 2 (ref. 4). The acids were detected with bromophenol blue indicator or by diazo reagent.

‡ Colour obtained by reaction with diazotized *p*-nitroaniline[7].

The predominant active metabolite of penicillin V in human beings is *p*-hydroxy isomer. In the urine of some persons who had received penicillin V, we found a second metabolite (probably the dihydroxy derivative), which remained at the start on the paper chromatogram (Fig. 1, lanes 1 and 3).

A more polar biologically active metabolite was also observed when the urine of persons who had received α-phenoxyethylpenicillin (phenethicillin) was examined (Fig. 1). Although the structure of this metabolite was not established, it seems very likely that hydroxylation of the benzene ring had also occurred.

The presence of active metabolites in the urine after administration of the following penicillins has been described: benzylpenicillin (penicillin *G*)[9,10], penicillin V, phenethicillin and propicillin[10], phenoxybenzyl penicillin (phenbenicillin)[10,11], 3,4-dichloro-α-methoxybenzyl penicillin[10,12], oxacillin and cloxacillin[10,13].

The hydroxylation of aromatic compounds in the organism is well known, and metabolites of this type have been described for such drugs as phenobarbital, diphenylhydantoin, and phenylbutazone[14]. These transformation products are often conjugated with glucuronic acid, and possibly penicillin V is transformed into a substance of this type that is inactive. Another inactive degradation product could be penicilloic acid, as was demonstrated with benzylpenicillin[15].

PHYSIOLOGY

A Serum Protein present in Pregnant Women

SMITHIES[1] has briefly mentioned a protein band which he found in the starch-gel electrophoretograms of sera from about 10 per cent of women who were either in late pregnancy or had recently delivered. In the work reported here, a much higher frequency has been found for what is probably the same protein band. In some runs in a borate gel at $pH = 8{\cdot}5$, under essentially the same conditions as described by Smithies[2], the protein of the investigation reported here migrated at a rate slightly slower than the first haptoglobin band of Hp 2–2 sera to which hæmoglobin had been added (Fig. 1). In other runs, the two were not separated. Accordingly, the typings for presence and absence of the band in Hp 2–2 sera are not included in the data given here although it was undoubtedly present in the majority of such sera.

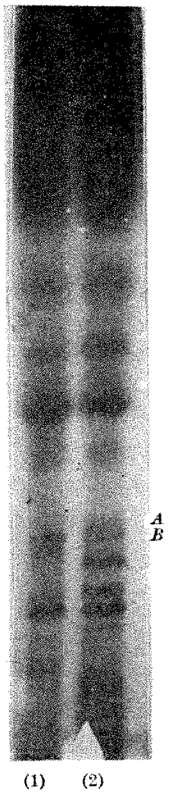

Fig. 1. Anode at the top of photograph. Starch-gel electrophoresis of two sera from pregnant women at 4–5 V/cm for 14 h in borate buffer (0·0092 M sodium hydroxide, 0·023 M boric acid $pH = 8{\cdot}5$) and staining with amido black 10*B*. (1) Haptoglobin type 1–1; (2) haptoglobin type 2–2; (*A*) first haptoglobin band of Hp 2–2; (*B*) pregnancy protein

The sera of 226 pregnant European women were examined and of these 141 were Hp 1–1, Hp 2–1 and Hp 0. The period of pregnancy has been divided into four seventy-day intervals and the frequency of occurrence of the band in each is shown in Table 1.

When the frequencies in the first and second intervals were pooled, χ^2 for heterogeneity was non-significant ($\chi^2_2 = 4{\cdot}767$, $0{\cdot}10 > P > 0{\cdot}05$).

Great variation in the concentration of the protein in different sera as judged by the intensity of staining with amido black 10*B* (Gurr) was observed. It is possible that more sensitive methods would detect it in sera from all pregnant women. In a group of 107 control sera from female blood donors 75 were Hp 2–1 or Hp 1–1 and one of these possessed a very faint band. The remainder did not possess a perceptible band.

Table 1. FREQUENCY OF THE OCCURRENCE OF A SPECIFIC SERUM PROTEIN AT INTERVALS OF PREGNANCY

Presence (+) or absence (—)	Interval of pregnancy (1) 0–70*	(2) 71–140	(3) 141–210	(4) 211 to end of pregnancy	Total individuals	% frequency
+	2	37	43	42	124	86
—	2	7	2	6	17	14
Total	4	44	45	48	141	100

* Days

The band was observed in three other individuals: (1) an Australian Aboriginal woman known to be pregnant, (2) a New Guinea native woman of adult age, for whom no information about pregnancy was available, (3) a European man whose carcinoma of the prostate was being treated with dienœstrol (50 mg twice a day).

Hirschfeld and Söderberg[3], using immunoelectrophoretic methods, have detected proteins in sera from pregnant women which were not present in control sera. It is possible that the protein reported here is identical with one of these proteins. It also seems likely that this protein is analogous to that found by Heim[4] and Beaton *et al.*[5], using starch-gel electrophoresis, in the serum of neonatal, tumorous and pregnant rats. Darcy[6] has demonstrated by immunological methods increased concentrations of a normal serum protein in the same classes of rats, and Heim[5] suggested that this protein and the one he detected by starch-gel electrophoresis are identical. The presence of the one and increased concentrations of the other appear to be concomitant with tissue growth and lactation in the rat.

The results presented here, however, do not exclude the possibility that the human protein is induced by increased levels of œstrogen; it has been demonstrated that the administration of œstrogen can induce the formation of specific proteins in the liver of the chicken embryo[7].

I thank Prof. L. W. Cox, Department of Obstetrics and Gynæcology, Queen Elizabeth Hospital, Adelaide, and Dr. H. B. M. Lewis of the Red Cross Blood Bank, Adelaide, for supplying sera. I also thank Prof. J. H. Bennett and Dr. M. J. Mayo for advice and Mr. I. R. Goodwins for the photography of Fig. 1.

Action of Prostaglandin E_1 on Tissues which respond to Bradykinin

PROSTAGLANDIN E_1 (9-keto, 11α, 15, dihydroxy-prost-13-enoic acid, PGE_1) was the first of several prostaglandins to be isolated by Bergström *et al.*[1,2]. It is a member of a chemically new group of vasodilator substances. Other naturally occurring vasodilators such as bradykinin, acetylcholine and histamine have effects on several types of tissue in addition to smooth muscle. For example, bradykinin increases capillary permeability, produces pain on application to a blister base and releases adrenaline from the adrenal medulla[3,4]. The actions of PGE_1 on these and other biological preparations have been investigated using bradykinin as a standard for comparison. The results are summarized in Table 1.

The vasodilator activity of PGE_1 was confirmed on the flow of blood in the hind-limb of a cat. Like bradykinin, it increased capillary permeability as shown by intradermal injection into guinea pigs pre-treated with Pont-

Table 1. THRESHOLD DOSES OR CONCENTRATIONS OF PROSTAGLANDIN E_1 AND BRADYKININ REQUIRED TO PRODUCE EFFECTS ON THE BIOLOGICAL PREPARATIONS USED IN THIS INVESTIGATION

Response	Preparation	PGE_1	Bradykinin
Vasodilatation	Cat hind limb	200 ng	20–100 ng
Increased capillary permeability	Guinea pig skin	100 ng	1–10 ng
Pain production	Human blister base	No effect (> 100 µg/ml.)	0.1 µg/ml
Adrenaline release	Cat adrenal medulla	No effect (> 7.5 µg/kg)	0.15 µg/kg
Reduced air entry	Guinea pig lungs	No effect (> 50 µg/kg)	4–10 µg/kg
Contraction of isolated smooth muscle	Rat uterus	60 ng/ml	0.5 ng/ml
	Guinea pig ileum	8 ng/ml	10 ng/ml
	Rat duodenum	(Contraction) 250 ng/ml	(Relaxation) 5 ng/ml

amine sky blue. A dose of 1 µg (in 0.1 ml.) produced a maximal effect. The intensity of bluing with PGE_1 was less for a given area of lesion than with bradykinin and the very intense bluing produced by bradykinin was never observed with PGE_1. Estimates of relative activity were therefore difficult to make but PGE_1 was at least 10–100 times less active than bradykinin.

PGE_1, unlike bradykinin (0.1 µg/ml.), did not cause pain on application to human blister bases in concentrations from 0.1 to 100 µg/ml. Retrograde injections of bradykinin (2 µg) into the cœliac artery of the 'Nembutal' anæsthetized cat released the equivalent of 1 µg of adrenaline from the adrenal medulla as detected by the denervated nictitating membrane. PGE_1 did not cause any detectable adrenaline release (< 0.2 µg) in doses up to 20 µg.

PGE_1 also differed from bradykinin in that it did not reduce air entry into the lungs of the guinea pig as measured by the Konzett and Rossler method. Like bradykinin, however, it caused contraction of the isolated rat uterus and the isolated guinea pig ileum; it further contracted the isolated rat duodenum, which is relaxed by bradykinin.

I thank Prof. S. Bergstrom of the Karolinska Institute, Stockholm, for the prostaglandin E_1, and Dr. E. D. Nicolaides, of Parke, Davis and Co., Ann Arbor, for the synthetic bradykinin used in these experiments.

Mechanism for concentrating Iodine in Marine Algae

THE fact that various marine algae are able to concentrate iodine against a gradient induced many workers to compare this mechanism with the uptake of iodine by the thyroid gland in mammals[1,2]. The reported results were incongruent in so far as some suggested that this mechanism may be similar[3], others, that it is different from the one operating in the thyroid gland[4].

All these experiments were performed on living tissue, which by virtue of their metabolic activities may have influenced to some extent these results. We have therefore examined the concentration mechanism on non-viable material.

The leaf-like fronds of seaweed, *Caulerpa* of the order Siphonales, cast ashore at the beaches of the Mediterranean (Tel Aviv), were collected during August and September. This material was then washed in filtered sea water, dried at room temperature and, after shredding, pulverized to a fine powder in a pharmacological mill of the Willy type. In order to compare with thyroid tissue the ability of these dried and pulverized algae to concentrate iodine, we used the method adopted in elucidating the role of different anions on the uptake of thyroid glands in our previous work[5,6]. 100 mg of the algae tissue powder dispensed in dialysis bags were submerged in beakers each containing 5 ml. of the medium solution. This medium solution consisted of different molar concentrations of $KClO_4$–KBF_4 and potassium iodide dissolved in sea water. The control medium consisted of sea water only. 0.1 ml. of carrier-free iodine-131 solution (Radiochemical Centre, Amersham, England), giving a count rate of 100,000 c.p.m. in a commercial well-type scintillation counter (Nuclear, Chicago), were added to each beaker.

All the experiments were run in duplicate and the counts did not differ by more than 2–5 per cent per experiment. The beakers were incubated at a temperature of 28° C for 120 min, then the bags containing the pulverized tissue were removed, adequately washed and assayed for the radioactivity in the well, after their volume had been made up to 2 c.c. with sea water. These measurements represent the tissue (T).

0.1 ml. of each of the medium solutions, again made up to a volume of 2 c.c. with water, were measured for their radioactivity in the well and represent in the results the medium (M).

The results are summarized in the table as T/M ratios, defined as the

$$\frac{\text{c.p.m. of } {}^{131}\text{I}/0.1 \text{ g pulverized tissue}}{\text{c.p.m. of } {}^{131}\text{I}/0.1 \text{ ml. medium}}$$

It is obvious from the results that all anions used reduced the T/M in comparison to the controls without these anions. The amount of reduction varies with the molar concentration, increasing with decreased concentration, reaching a maximum and then decreasing again.

The molar concentrations for maximal reduction in uptake of iodine-131 in the algae was for iodide 10^{-5}, for fluoroborate 10^{-6} and for perchlorate 5×10^{-7}, being very similar to those found by Wolff and Maurey in their experiments with animal tissues[7].

Table 1. DEPRESSION OF THE T/M BY DIFFERENT ANIONS

T/M of control = 12.1 ± 1.6

Molarity	T/M with $KClO_4$	T/M with KBF_4	T/M with KI
10^{-2}	9.5 ± 0.45	10.3 ± 1.15	0.25
10^{-3}	9.3 ± 0.4	10.4 ± 1.15	3 ± 2
10^{-4}	8.7 ± 0.65	9 ± 0.45	4 ± 1
10^{-5}	9 ± 0.5	9.2 ± 0.6	6.1 ± 0.5
10^{-6}	8.4 ± 0.8	7.5 ± 1.6	6.6 ± 0.3
5×10^{-7}	7.5 ± 0.9	9.1 ± 1.8	
10^{-7}	7.8 ± 0.7	11 ± 1.85	

The figures represent the mean and standard deviation.

Our previous assumption, therefore, that ionic size is of importance in the uptake mechanism seems to be verified with the additional restriction that probably more parameters of the ion-like univalency, proper size and structural properties are of importance. The ionic size itself is, as Wolff pointed out, an operative one and depends on the conditions under which it is measured, its hydration state being of utmost importance. There seems to be an optimal concentration which determines the operational ionic volume in such a gradient and which varies for different ions. This may partly explain the failure of Tong to account for any depression of the T/M in his algae experiments with potassium perchlorate in only a 10^{-3} molar solution.

As the inhibition of iodine uptake may not be identical with the concentration mechanism, we undertook also experiments with labelled $K^{36}ClO_4$. The preliminary results of these showed again a concentration of the $K^{36}ClO_4$ ion in the algae. Further experiments, which are in progress, show also an increase of this uptake under the influence of bovine thyroid-stimulating hormone (Organon), adding again to the similarity of the uptake mechanism in the algae and thyroid glands[8].

These results indicate that by all the criteria used the concentration mechanism of iodine in algae and thyroid glands resemble each other or may be even reduced to an identical fundamental property of the specific tissue, not necessarily connected with its vital organization in the living cell

Lung Lining in Bird, Reptile and Amphibian

The lungs of mammals are lined with a film of lipoprotein, which has the function of reducing the tension of the sharply curved alveolar surface[1] A similar film was also found to exist in the pigeon and the frog[2] Miller and Bondurant[3] and Klaus *et al* [4] have, however, concluded as a result of a study of the surface properties of saline extracts of minced lung from turtle, frog, and pigeon that a distinctive surface-active material exists in mammalian lungs only We have, therefore, re-examined the question

The species used were the chicken (*Gallus*), slow-worm (a legless lizard, *Anguis fragilis*), and clawed toad (*Xenopus laevis*) The lungs of these were compared with those of mammals; a summary of the findings is given in Table 1 The methods used have been described elsewhere[2,5,7]

Small bubbles, squeezed from a fragment of mammalian lung into a hanging drop of air-saturated water, usually contract somewhat and then remain stable The ratio of final (stable) to initial surface area is called the stability ratio, for bubbles initially between 36μ and 60μ in diameter the mean stability ratio is about 0 7 Ordinary bubbles of this size, for example those formed in blood, contract and disappear in a few minutes In our experiments we found that bubbles squeezed from fragments of the bird, reptile, and amphibian lungs were as stable as those from mammalian lungs, the smallest of them were stable enough and small enough to show Brownian motion

When bubbles (say 100μ in diameter) from mammalian lung are immersed in de-aerated water under a glass slide, they first flatten as the air dissolves and the surface tension falls, and then suddenly resume at an almost spherical shape, in the latter process, the equatorial diameter is reduced by about 10 per cent The phenomenon is known as 'clicking', and repeats itself rhythmically as the bubble dissolves, it demonstrates[6] that the bubble surface has a free energy in excess of the product of its area and surface tension Bubbles from bird lung behaved in de-aerated water exactly like those from mammalian lung; those from the slow-worm showed less prominent 'clicking', while those from toad lung did not 'click', but contracted steadily

Table 1 PROPERTIES OF BUBBLES FROM THE LUNGS OF MAMMAL, BIRD, REPTILE AND AMPHIBIAN, COMPARED WITH THOSE OF ORDINARY BUBBLES

	Bubbles from lungs of				Bubbles in blood, etc
	Mammal	Chicken	Slow-worm	Toad	
Stability ratio of bubbles from fresh lung (means of batches of 30)	0 60–0 87	0 74 0 78	0 73 0 80	0 81 0 82	0 0
Brownian motion	+	+	+	+	–
Clicking (per cent decrease in equatorial diameter)	10%	10%	2%	nil	nil
Stability ratio of bubbles from lung collapsed once and re-inflated (means of batches of 30)	0 60–0 87	0 73 0 80	0 16*	0 06 0 29 0 39	0 0
Stability ratio of bubbles from lung washings (means of batches of 10)	0 5–0 9	0 6 0 7	0 0	0 1 0 1	0 0

* Mean of batch of five bubbles

A mammalian lung may be made to collapse to an air-free state by exposure to a vacuum followed by sudden restoration of atmospheric pressure If it is then re-inflated, it retains much of the air forced into it, and fragments from it give stable bubbles like those from fresh lung[2] We found that when chicken lung was collapsed, and air was injected into the tissue, fragments from the lung when squeezed into air-saturated water gave bubbles as stable as those from mammalian lung The slow-worm and toad lungs, on the other hand, when collapsed and re-inflated, retained little air, showed a strong tendency to collapse again spontaneously, and yielded bubbles much less stable than those from fresh lungs

If washings from mammalian lungs are carefully freed from any bubbles they may contain, and are then frothed by blowing air from a needle into the liquid[7], they form bubbles with stability ratio usually in the range 0 5–0 9 Injection of saline into the bird lung tissue, and recovery of the saline by squeezing, produced washings resembling in this respect those from mammalian lung Washings from the slow-worm and toad lungs, however, provided few stable bubbles

It is evident from these findings that a surface film capable of reducing to a large degree the tension of the surfaces of the fine air spaces of the lung exists in the bird, reptile and amphibian, as well as in mammals The lung lining film of the toad is, however, less elaborate than that of the slow-worm, which is in turn less elaborate than that of the bird or mammal The failure to re-form a complete film after collapse and re-inflation, and the poor stability of bubbles from lung washings, in the toad and slow-worm show that these have only a small reserve of the saline-dispersible 'lining complex' from which the lining film is formed; the smallness of this reserve would explain the weakness of the surface film on the extracts of amphibian and reptile lung studied by other workers[3,4] Our experiments provide no evidence as to whether the bird has a greater or smaller supply of complex than has the mammal

The curvature of the surfaces of the air spaces in reptile and amphibian is less than in mammal or bird, and it is not unexpected that their supply of surface-active agent should be less than in the warm-blooded classes In the mammal, the alveoli would collapse if the surface film were absent, or, if the lung were held open by air pressure, transudation from the blood capillaries into the alveoli would occur In the bird, collapse of the lung may in part be prevented by its more rigid structure (though it can, as stated here, be collapsed artificially), to prevent transudation, however, a surface film is even more necessary than in the mammal, because the curvature of the walls of the air capillaries of the bird is even sharper than that of the walls of the mammalian alveoli

PHARMACOLOGY

Effect of 'Tremorine' and some Anti-Parkinson's Disease Drugs on Acetylcholine in the Rat's Brain

Giarman and Pepeu[1,2] have demonstrated that atropine sulphate and scopolamine hydrobromide decrease total brain acetylcholine in the rat. Both drugs are effective against Parkinson's disease and prevent the tremor, rigidity and the parasympathetic stimulation induced by the administration of 'Tremorine' (1,4-dipyrrolidino-2-butyne)[3].

In the present work the effects of 'Tremorine' and of some anti-Parkinson's disease drugs on brain acetylcholine have been investigated. Adult male rats 150–200 g were killed by decapitation at the time stated in each experiment. The brain (excluding cerebellum, olfactory lobes and pituitary) was removed quickly and total acetylcholine was extracted by the method of Smallman *et al.*[4] The acetylcholine content of the extracts was estimated on the isolated eserinized rectus abdominis muscle of the frog. The values for acetylcholine are expressed in terms of acetylcholine chloride. The effect of the various drugs used was carefully examined on the rectus abdominis in order to compensate for any influence on the response of the muscle to acetylcholine. All the drugs were administered to the rats intraperitoneally in 0·1–0·4 ml.

Table 1 shows that 'Tremorine' induces a marked rise of total brain acetylcholine which closely follows the onset of the symptoms. This finding is in agreement with the observation of Stern *et al.*[5] that 'Tremorine' stimulates brain cholineacetylase. Pretreatment of the rats with either atropine sulphate or caramiphen hydrochloride prevents the onset of the tremor, rigidity and parasympathetic stimulation induced by the injection of 'Tremorine' and completely prevents the increase of brain acetylcholine. 'Tremorine' has been shown to be a weak inhibitor of the cholinesterase of the erythrocytes and intestinal mucosa[6]. Atropine sulphate, on the other hand, does not prevent the increase of brain acetylcholine caused by the injection of eserine sulphate, which is presumably due to the inhibition of brain cholinesterases (Pepeu, unpublished work). Also diethazine, an anti-Parkinsonism drug of the phenothiazine type, prevents the onset of the symptoms caused by 'Tremorine'. Diethazine diminishes but not always abolishes the increase of brain acetylcholine due to 'Tremorine'. In fact 50 per cent of the rats in the group treated with diethazine and 'Tremorine' had a brain-level of acetylcholine higher than 3 µg/g. Nevertheless, all the rats had very little or no symptoms. Ahmed *et al.*[7] have shown that of the established anti-Parkinson's disease drugs diethazine is the least potent antagonist of acetylcholine on the isolated guinea pig ileum. Moreover, we have noted that caramiphen, like atropine, decreases brain acetylcholine but diethazine does not, as may be seen in Table 2. The rats injected with diethazine are slightly sedated whereas those injected with caramiphen show an increase of the spontaneous motility.

The results reported show a difference between the anti-Parkinson's disease drugs of the atropine type and those of the phenothiazine type. They do not give a definite evidence that the increase of brain acetylcholine is responsible for the symptoms induced by 'Tremorine'. Since 'Tremorine' also increases brain histamine in the rat[8] and depletes brain norepinephrine[9], the mechanism of action of this drug seems to be very complex and its action on brain acetylcholine only one of its aspects.

Table 1

Drugs	No of animals	Dose (mg/kg)	Time (min)	ACH (µgm/gm ± *S E*)	Changes (%)	Remarks

Phenylquinone Writhing Test: Interpretation of Data

THE antagonism of phenylquinone (2-phenyl-1,4-benzoquinone)-induced writhing in mice has been recommended for investigating weak analgesic activity of new compounds[1,2], but the non-specificity of this test has been emphasized by Hendershot and Forsaith[3]. Many compounds not considered to be analgesics, for example, parasympathomimetics, sympathomimetics and central nervous system stimulants, protect mice against the writhing induced by phenylquinone. During the routine pharmacological screening of new compounds, we observed an apparent correlation between *in vitro* anti-5-hydroxytryptamine activity and the ability of a compound to antagonize phenylquinone-induced writhing. Therefore, to determine more precisely the value of this test in a routine screening programme, it was decided to investigate in more detail the writhing response and its modification by compounds and procedures known to affect the activity and metabolism of biogenic amines.

The *in vitro* anti-5-hydroxytryptamine activity of compounds was investigated using the isolated œstrus rat uterus preparation. Dose-response curves to 5-hydroxytryptamine (5HT) were obtained in the presence or absence of varying concentrations of antagonist and the concentration of antagonist required to reduce the sensi-

Table 1 COMPARATIVE *in vitro* ANTI-5HT AND *in vivo* ANTI-PHENYLQUINONE ACTIVITIES OF LSD, HOMOCHLOROCYCLIZINE, PROMETHAZINE AND MEPYRAMINE

Compound	Anti-5HT activity		Anti-phenylquinone activity	
	Concentration to reduce uterine sensitivity 10 times (µg/ml)	Relative potency	ED_{50} (95 per cent confidence limits) (mg/kg)	Relative potency
LSD	0 01	1	0 019 (0 012–0 030)	1
Homochlorcyclizine	0 25	0 04	6 80 (4 50–10 9)	0 0028

Mepyramine	> 2 5	< 0 004	133 (80 6–220)	0·0001

Table 2. EFFECT OF REPEATED INTRAPERITONEAL INJECTIONS OF PHENYLQUINONE ON THE WRITHING RESPONSE IN MICE

Day	1	2	3	4	5
Writhes to phenylquinone (percentage of control)	100	54	11	3	0

2 mg/kg phenylquinone was injected once daily on each of five successive days to a single group of mice, on each day a fresh group of animals was injected with phenylquinone to serve as control

tivity of the preparation by a factor of 10 was calculated Compounds were also investigated for their ability to antagonize phenylquinone-induced writhing, essentially by the method of Hendershot and Forsaith[3] Compounds were administered orally, dissolved or suspended in 5 per cent gum acacia, to groups of 6 starved male albino mice (Tuck strain) weighing 18–22 g One hour later, unless otherwise stated, each animal received an intraperitoneal injection of phenylquinone, 2 mg/kg The total number of writhes in a group of 6 animals was counted for the 20-min period immediately following the phenylquinone injection A new aqueous solution of phenylquinone was prepared using gentle heat before individual experiments. The solution was kept in an amber glass bottle, stoppered when not in use, in order to avoid decomposition of the phenylquinone The ED_{50} of a compound (the dose required to reduce by 50 per cent the number of writhes induced by phenylquinone treatment alone) was calculated by the method of Litchfield and Wilcoxon[4] To improve the precision of the determinations, duplicate experiments were performed

d-Lysergic acid diethylamide (LSD), homochlorcyclizine and promethazine are known to antagonize the effects of injected or released 5HT, mepyramine is less active in this respect The comparative activities of these compounds in antagonizing phenylquinone-induced writhing in mice together with their *in vitro* anti-5HT activities are summarized in Table 1 Eckhardt, Cheplovitz, Lipo and Govier[5] have suggested that the release of 5HT may be a factor in the phenylquinone writhing response It was thought that if the release of 5HT was implicated, then repeated intraperitoneal injections of phenylquinone to an animal would deplete the intestinal tissues of 5HT and decrease the number of writhes obtained at each injection A group of 6 mice was injected with phenylquinone on each of 5 successive days, each day a fresh group of animals was injected with phenylquinone to serve as controls The results of this experiment, summarized in Table 2, show that repeated injections of phenylquinone caused the expected reduction in the number of writhes We also found that the 5HT content of the small intestine of animals given 5 injections of phenylquinone was only 60 7 per cent that of untreated animals, in a further experiment a single injection of phenylquinone reduced the 5HT content of intestinal tissue to 76 3 per cent that of untreated animals in 1 h The 5HT was determined by a spectrofluorometric method[6] It is not known whether the depletion of 5HT by phenylquinone is a specific drug effect, but although treated animals exhibited diarrhœa, autopsy did not reveal obvious irritation or damage to the intestinal tract

The effect of phenylquinone was next investigated in mice sensitized to 5HT by adrenalectomy since Higginbotham[7] has shown that there is up to a 25-fold increase in sensitivity to 5HT in these animals We have found that the sensitivity of mice, adrenalectomized 5 days previously, to injected phenylquinone was markedly increased, a 69 per cent increase in the writhes being observed

Next, the effects of hydrazine and non-hydrazine monoamine oxidase inhibitors (MAOI) were investigated in the phenylquinone test, since these compounds are known to increase tissue concentrations of 5HT In view of the results obtained with 5HT antagonists, MAOI's were expected to potentiate the writhing response Surprisingly, tranylcypromine, phenelzine and iproniazid administered orally 4 h prior to the phenylquinone injection showed definite antagonistic activity to the writhing response (Table 3), and their potencies in this respect closely followed their activities as inhibitors of monoamine oxidase Harmine and pargyline also inhibited the writhing response This result need not necessarily preclude involvement of 5HT in the writhing response since MAOI's might inhibit its release from peripheral stores

Table 3 ANTAGONISTIC EFFECTS OF MONOAMINE OXIDASE INHIBITORS ON THE PHENYLQUINONE WRITHING RESPONSE IN MICE

Compound	ED_{50} (95 per cent confidence limits) (mg/kg)
Tranylcypromine	3 70 (2 21–6 18)
Phenelzine	7 70 (3 50–16 9)
Iproniazid	112 (62 2–201)

As a result of these tests two additional classes of compounds, 5HT antagonists and MAOI's, have been shown to be potent inhibitors of phenylquinone-induced writhing in mice This adds to the type of compounds already known to be active in this test. One might, therefore, ask if the test has any predictive value in the pharmacological evaluation of new compounds Certainly, a positive result can no longer be regarded as indicating a high probability of weak analgesic or anti-inflammatory activity However, we believe the test is of value as a simple primary screening test to detect a diversity of known pharmacological types These have to be characterized more fully by other tests

Production of 6-Aminopenicillanic Acid by Dermatophytes

FOLLOWING the isolation of 6-aminopenicillanic acid (6-APA) by Batchelor *et al* [1,2], a number of papers dealing with its formation both by fermentation and by microbial hydrolysis have been published[3] Cole and Rolinson[4] recently reported on production of 6-APA by certain species of *Cephalosporium* and *Emericellopsis*

As we showed some years ago that *Trichophyton* strains were able to produce penicillins[5,6], dermatophytes were examined for production of 6-APA For this purpose, 70 dermatophyte strains were examined The experiments were carried out in shaken cultures in precursor-free media The quantity of 6-APA was measured by a fast biological method[7] and was identified also by paper chromatography. Each test was repeated three times in duplicate. A proto-

Table 1. Production and/or Formation of 6-Aminopenicillanic Acid by Dermatophytes (Units/ml. in Terms of Benzylpenicillin)

Strains	Activity of fermentation broth	6-APA in fermentation broth	6-APA in acetonic extract of myc.	Penicillinacylase activity of for penicillin *G*		penicillin *V*	
				broth	mycel.	broth	mycel.
Epidermophyton interdigitale	1·5	0·2	6·0	6–20	20–50	80–600	300–900
Trichophyton gypseum	0·6	0·9	0·5	0·7–1	1–5	9	30–50
T. gypseum	0·0	0·06	0·0	6	2–10	20–100	80–150
T. gypseum	0·3	0·2	0·4	1	1–6	20–50	20–60
T. mentagrophytes	5·0	±	0·0	1–4	4–8	60–150	300–400
T. interdigitale	1·5	±	±	1–2	80–150	10–30	50–200

type is shown in Table 1. All values in Table 1 represent benzylpenicillin units per millilitre.

The first section of Table 1 shows the quantity of 6-APA produced through fermentation, and the second indicates the penicillinacylase activity of the same strains. The first column shows the total antibiotic activity of the fermentation fluid, the second shows the 6-APA content free in the broth, and the third one discloses the amount of 6-APA in the concentrated acetonic extract of the washed mycelium[8].

As may be seen, dermatophytes are capable of synthesizing 6-APA in various amounts, just like other penicillin-producing moulds are.

Furthermore, the penicillinacylase activity of the fermentation broth and separately that of the washed mycelium of dermatophytes was examined. The values reveal that dermatophytes are able to produce both endo- and exo-cellular penicillinacylase, and that they form 6-APA from phenoxymethylpenicillin more readily and abundantly than from benzylpenicillin. Mycelium generally has a higher activity than fermentation fluid. This is generally characteristic of moulds. Production of penicillinacylase by dermatophytes can be increased by administering the adequate acid.

The presence of penicillinacylase activity in dermatophytes is thus shown, and that 6-APA could be a product of dermatophytes is suggested. This may be the reason of the ineffectiveness of penicillins in the treatment of fungal infections caused by dermatophytes.

Increased Concentrations of Blood Lipids in Guinea Pigs poisoned by Sarin

In the course of routine withdrawal of blood samples from guinea pigs treated with the anticholinesterase sarin (isopropyl methylphosphonofluoridate) it was noticed that samples taken from some animals were milky in appearance. This visible hyperlipæmia was found to be more prevalent in the female, and this communication describes the experiments which led to this finding.

Male and female guinea pigs from the local colony (500–800 g) were injected subcutaneously with sarin (1,500 µg/kg, that is, approximately 30 LD_{50} doses) and treated intramuscularly with an oxime, 2-hydroxyiminomethyl-*N*-methyl pyridinium methane sulphonate (P2S) 30 mg/kg, and atropine 1 mg/kg. The cholinesterase reactivator P2S and atropine were administered to ensure that a reasonable number of survivors (approximately one-third of the injected animals) would be obtained despite the high dose of sarin.

Because the majority of the survivors of sarin poisoning were spastically paralysed and incapable of, or disinterested in, feeding or drinking, both the survivors and the controls were deprived of feed and water during the experimental period.

Three days after the injection of sarin, the animals were killed and blood samples were drawn from the heart (chest opened after blow on the neck). The blood samples were allowed to clot and spun in a centrifuge at 1,900*g* for 20 min and the entire supernatant was collected for analysis. Phospholipid concentrations determined as lipid phosphorus[1,2] were used as indexes of the degree of lipæmia.

Cholesterol was also estimated in the earlier stages of the experiment, but since the rise in total cholesterol paralleled the increase in lipid phosphorus, they were discontinued.

As illustrated in Fig. 1, the difference in lipid content between samples of blood drawn from poisoned animals and controls was evident to the eye. As the samples cooled to room temperature, large masses of lipid material precipitated from solution. In the sample drawn from the female guinea pig with hyperlipæmia illustrated in Fig. 1 the lipid phosphorus was 30·6 mg per cent whereas that of the control was 3·4 mg per cent.

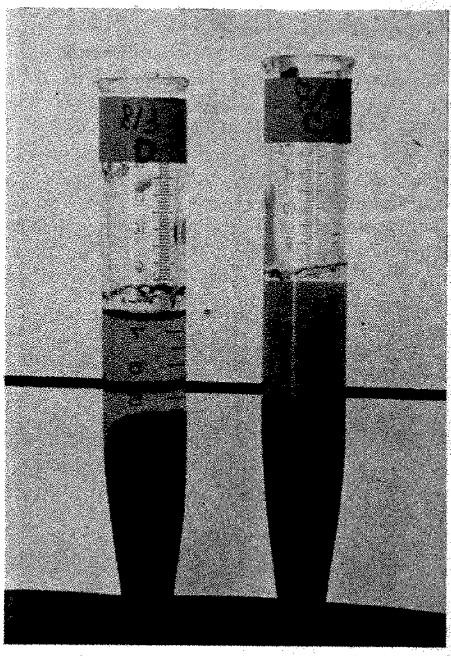

Fig. 1. Hyperlipæmia in a female guinea pig treated with sarin (1,500 µg/kg)

Left test-tube, lipid phosphorus = 3·4 mg per cent; right test-tube, lipid phosphorus = 30·6 mg per cent

Notice that the black line drawn behind the test tubes cannot be seen behind the hyperlipæmic sample. The photograph is shown to emphasize the point that the lipid phosphorus measured is only one component of a general hyperlipæmia

Referring to Table 1, the subcutaneous administration of sarin, 1,500 μg/kg, to female guinea pigs caused a significant increase of lipid phosphorus, the mean being 16·6 mg per cent in the survivors as compared with 3·0 mg per cent in female controls. This increase was more prevalent in females, the mean concentration of lipid phosphorus being the same in male guinea pigs whether sarin-poisoned or controls. Only three males had definite raised lipid phosphorus (15·0, 6·6 and 5·8 mg per cent) out of 29 survivors poisoned with sarin.

Table 1. LIPID PHOSPHORUS CONCENTRATIONS (MG PER CENT) OF SARIN-TREATED AND UNTREATED MALE AND FEMALE GUINEA PIGS

$S_{FC}^2 = 0·95$		$S_{FE}^2 = 393·9$		$S_{MC}^2 = 0·21$	$S_{ME}^2 = 7·2$	

n = number of animals ; $\overline{X}$ = means ; S^2 = variance.

Difference in weight loss during the three days offered no explanation of the sex difference, loss of weight being approximately the same for both sexes (21·4 and 23·0 per cent respectively : Table 2). Attempts to correlate loss in weight and degree of hyperlipæmia in the case of individual animals gave negative results. Also, it is not sufficient to say that the acute effects of sarin poisoning caused the observed increase in blood lipids since only three male guinea pigs showed elevated blood lipid phosphorus. Animals which showed no hyperlipæmia were as spastically paralysed as those with increased blood lipids. All surviving animals showed some degree of paralysis, but it varied greatly in intensity, ranging from a few showing very little paralysis of their limbs to a few which could not right themselves (involvement of all four limbs).

Table 2. MEAN PERCENTAGE LOSSES IN WEIGHT OF SARIN-TREATED AND UNTREATED MALE AND FEMALE GUINEA PIGS (LISTED IN TABLE 1)

Females		Males	
Controls – treated with P2S and atropine	Experimental – treated with sarin, P2S and atropine	Controls – treated with P2S and atropine	Experimental – treated with sarin, P2S and atropine
16·7	21·4	20·2	23·0
[95% confidence limits 9·9–23·5]	[95% confidence limits 14·6–28·2]	[95% confidence limits 15·2–25·2]	[95% confidence limits 15·6–30·4]

A possible explanation of sarin-induced hyperlipæmia is inhibition of esterases (including cholinesterases) concerned in lipid metabolism. Gerebtzoff[3] expressed the opinion that there is "some vague relationship between cholinesterases and lipid metabolism". To explain the sex difference observed, it is necessary to postulate either that the esterases differ in the two sexes or that they are rendered susceptible to inhibition by sarin by some factor peculiar to the female. Kritchevsky *et al.*[4] have stated that there are differences in cholesterol metabolism between male and female rats which can be influenced by gonadectomy and œstrogenization. Also, they found that only some of the rats oxidized cholesterol at some fixed rate whereas another group of rats within the population oxidized cholesterol at a higher rate. The results presented by Kritchevsky *et al.*[4] are similar to those presented here in that females show a greater frequency of increased lipid concentration after sarin treatment than males and also within one group, say the females, some show no increase in lipid phosphorus whatsoever whereas others exhibit hyperphospholipidæmia to a marked degree (range of lipid phosphorus 1·4–59·6 mg per cent).

A reference should be made to the fact that sarin is an established neurotoxic agent in chickens[5], causing demyelination and axonal degeneration. Increase in certain blood lipids may possibly reflect biochemical lesions as yet unknown, which have neurotoxic effects. Guinea pigs are said to be resistant to paralysis with neurotoxic compounds[6], but demyelination occurs in rats which are also said to be resistant[7]. There is, however, to our knowledge, no reference in the literature to any difference in degree of neurotoxicity based on sex.

HÆMATOLOGY

Formation of Ferrihæmoglobin of Isolated Human Hæmoglobin Types by Sodium Nitrite

THE sensitivity of hæmoglobins to oxidation by potassium ferricyanide and sodium nitrite ($NaNO_2$) has been examined extensively[1,2]. During treatment of oxyhæmoglobin with $NaNO_2$, both components are oxidized through a combination of different reactions, the total reaction being summarized as follows: $NaNO_2 + 2R\text{–}Fe^{++}O_2 + H_2O \rightarrow NaNO_3 + 2R\text{–}Fe^{+++}OH + O_2$ (ref. 2). The rate of ferrihæmoglobin formation by the action of $NaNO_2$ can be calculated from the sigmoid curve representing the relation between reaction time and per cent of ferrihæmoglobin and is expressed as the time required for 50 per cent oxidation of the hæmoglobin (*T* 1/2). It has been demonstrated that the hæmoglobin of cord red blood cells, which is composed mainly of fœtal hæmoglobin (Hb-F), is particularly sensitive to treatment with $NaNO_2$. Since the structural difference between Hb-F and Hb-A is located in one of the two types of polypeptide chains, Hb-F being composed of 2 α-chains and 2 γ-chains ($\alpha_2\gamma_2$) and Hb-A of 2 α-chains and 2 β-chains ($\alpha_2\beta_2$), the possibility is present that $NaNO_2$ will react differently with human hæmoglobin types of other structural composition.

The following human hæmoglobin types have been investigated: Hb-A; Hb-S ($\alpha_2\beta_2^{6\text{val}}$, ref. 3); Hb-C ($\alpha_2\beta_2^{6\text{lys}}$, ref. 4); Hb-F; Hb-Bart's (γ_4, ref. 5); Hb-A_2 ($\alpha_2\delta_2$); Hb-A_2' a variant of Hb-A_2 (ref. 6); Hb-Lepore, composed of normal α-chains and of 'β' chains being related to the β-chain of Hb-A and the δ-chain of Hb-A_2 (ref. 7); Hb-A, GSSG, a mixed disulphide of Hb-A and glutathione with the following formula $\alpha_2\beta_2(SSG)_2$ (ref. 8); Hb-M-Kankakee, an abnormal methæmoglobin composed of abnormal α-chains and normal β-chains (ref. 9). The Hb-Bart's and Hb-M-Kankakee were isolated by preparative CM-cellulose chromatography (ref. 10); all other hæmoglobin components by preparative DEAE-cellulose chromatography (ref. 10) at 4°–10° C within 5 h. The isolated oxyhæmoglobins were dialysed against distilled water at 4° C for 24 h The methæmoglobin formation rates were investigated 26–30 h after the isolation following the technique described by Betke *et al* [2] The concentration of each solution was adjusted in such a way that the optical density read 0 800 ± 0 005 at 500 mμ using the Beckman *DU* spectrophotometer and 1-cm quartz cuvettes The solution was kept at room temperature for 1 h and diluted with an equal volume of a 0 2 M sodium phosphate buffer at *p*H 7 00 ± 0 02 The formation of ferrihæmoglobin was measured, after introducing 0 05 ml of a 0 025 M NaNO$_2$ solution with a micro-syringe (accuracy 1 per cent) into 3 0 ml of the hæmoglobin–phosphate buffer mixture, by determining the increase of optical density at 500 mμ at certain time intervals The oxidation was found completed when no further increase in the optical density readings at 500 mμ was observed, which was confirmed by the determination of the spectra between 430 and 700 mμ using the Beckman *DK*-2 spectrophotometer The molar ratio between hæmoglobin (calculated on 1/4 of the molecular weight at 68 000) and NaNO$_2$ was 1 5 9 In some experiments 0 1, 0 075, and 0 0375 ml of NaNO$_2$ solutions were added to the hæmoglobin solution The rate of ferrihæmoglobin formation of the isolated buffered Hb-M-Kankakee (initial optical density readings 0 780 and 0 785) was measured by determining the decrease in optical density readings at 576 mμ (Beckman *DU*, 1-cm quartz cuvettes)

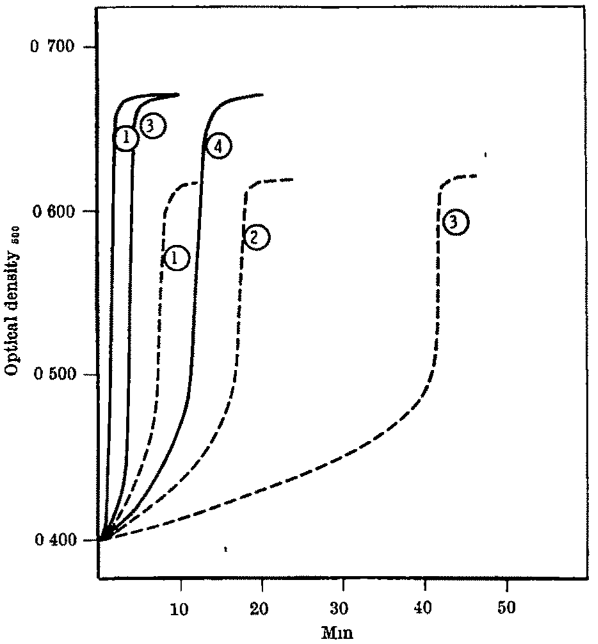

Fig 1 Curves representing the relation between the reaction time and the increase in the production of ferrihæmoglobin 1, 0 1 ml, 2, 0 075 ml, 3, 0 05 ml, 4, 0 0375 ml M 0 025 sodium nitrite ——, Hb-A$_0$, – – –, Hb-A$_2$

From the ferrihæmoglobin formation curves in Fig 1, it is evident that isolated Hb-A$_2$ is more resistant to NaNO$_2$ oxidation than Hb-A$_0$ When the *T* 1/2 values of isolated Hb-A$_2$, Hb-A$_2$′ and Hb-Lepore were compared with the *T* 1/2 values of Hb-A$_0$ fractions, which were isolated concurrently, a 7–11-fold decrease in the rate of ferrihæmoglobin formation was found The β-chain abnormalities, Hb-S and Hb-C, did not differ from Hb-A The *T* 1/2 values established for Hb-F ($\alpha_2\gamma_2$), Hb-Bart's (γ_4) and Hb-A-GSSG were 0 41, 0 23 and 0 61 times the *T* 1/2 value of Hb-A$_0$ respectively It seems, therefore, that hæmoglobin types composed of α-chains and normal or abnormal δ-chains are oxidized by NaNO$_2$ at a low rate, while the oxidation of normal Hb-A or hæmoglobin components with abnormal β-chains is intermediate between those of Hb-A$_2$ and the γ-chains containing Hb-F Alteration of the β-chains of Hb-A by the introduction of one glutathione residue into each β-chain increases the ferrihæmoglobin formation rate Hb-Bart's is oxidized at an extremely high rate

Another feature of the sigmoid oxidization curves (Fig 1) is an initially slow increase in the formation of ferrihæmoglobin, while a steep rise was observed when about 50 per cent of the available ferrous iron of the hæmoglobin was oxidized These observations may indicate that during the action by NaNO$_2$ the ferrous iron of the hæm groups of the δ- or β- or γ- chains is oxidized first (at different rates), followed by an extremely rapid oxidation of the ferrous iron of the hæme groups of the α-chains, which are commonly present in Hb-A, Hb-F and Hb-A$_2$ This hypothesis has been supported by investigations of the sodium nitrite oxidation of isolated Hb-M-Kankakee The oxidation of the unaltered ferrous iron of the hæm groups of β-chains was found to proceed slowly, the curves being hyperbolic rather than sigmoid in shape

The final increase occurring after the logarithmic rise in optical densities of Hb-A$_2$, Hb-A$_2$′ and Hb-Lepore at 500 mμ by the action of NaNO$_2$ was always considerably less than those observed for Hb-A and its variants and for Hb-F (Fig 1) No additional increase was seen after the addition of excess oxidant The visible spectra of the ferrihæmoglobin derivatives of Hb-A$_2$, Hb-A$_2$′ and Hb-Lepore and of Hb-A, measured at a *p*H of 7 0, offered the explanation for these observations since notable differences were present The millimolar extinction values for the isolated Hb-A$_2$ at the wave-lengths 630, 565, 530 and 500 mμ were 3 15, 5 85, 8 25 and 8 65 and for the isolated Hb-A$_0$ 3 8, 4 95, 7 65 and 9 35 respectively The spectra of the oxy-, reduced, CO–, and cyanmethæmoglobin derivatives of Hb-A$_2$ and Hb-A were identical It is noteworthy that similar spectral deviations were observed when Hb-A$_2$ and Hb-A$_0$ were oxidized by potassium ferricyanide

Role of Liver in the Inactivation of Erythropoietin

THERE is still considerable uncertainty as to the site or sites of inactivation of erythropoietin (ESF) Jacobsen *et al* [1] found that plasma extracts obtained from rabbits treated with acetylphenylhydrazine (APH) showed definite ESF activity when tested in hypophysectomized rats These APH-treated rabbits had evidence of liver damage In plasma extracts obtained from animals without evident liver damage, no erythropoietic activity was observed Prentice and Mirand[2,3] placed normal rats under low oxygen tension (8–12 per cent) and did not detect ESF in their plasma When the experiment was repeated on rats treated with carbon tetrachloride, ESF was found in the plasma When plasma obtained from animals treated

9	ESF incubated with saline solution	6 1	1 1	2 0	4 3

* ESF Armour Lot No *K*, from APH sheep plasma

Bioassay values represent mean of at least 6 rats per group

Groups 2-5 each rat received a volume of perfusate to which 4 2 cobalt units of ESF had been added, groups 6-9 a volume of perfusate to which 2 8 cobalt units had been added

Liver and spleen were also analysed and showed similar patterns

with APH was injected directly into the portal vein, no erythropoietic response was observed When such plasma was injected into the jugular vein, a definite effect was obtained From this observation they concluded that liver has a role in the inactivation of ESF

Burke and Morse[4] perfused livers from normal rats with blood obtained from rats treated with cobaltous chloride They assayed for ESF by measuring uptake of iron-59 by red blood cells *in vivo* by fasting rats, and significant decrease in ESF activity was observed within 3 h of perfusion When similar experiments were performed with carbon tetrachloride poisoned livers, no reduction in ESF-level was observed They therefore concluded that the liver participates in the removal of ESF from the blood

Stohlman and Brecher[5] showed that plasma obtained from APH-treated rabbits was active whether or not there was liver damage Later, Stohlman[6] showed that in animals where the bone marrow was damaged by irradiation the ESF-levels were higher than in controls and it was concluded that bone marrow may be the site of utilization and/or inactivation of ESF. These conflicting results have led us to re-examine this problem in the isolated perfused rat liver system where known amounts of exogenous ESF were added to the perfusate

Rat livers were perfused by the method of Miller *et al* [7] Plasma was separated and the buffy coat removed The red blood cells were washed with Ringer's solution, diluted to 2 3 times their volume with Ringer's solution and 25 mg heparin and 140 mg glucose added The total volume of the perfusate was 100 ml

The liver was perfused for 30 min 20 ml of perfusate were then removed and kept inside the perfusion chamber as a control (Table 1, group 1) A sheep plasma ESF preparation was added to the perfusate in amounts of 3 cobalt units/ml and samples were taken at the times indicated in Table 1 The red blood cells were separated and the supernatant was refrigerated until the bioassay was performed The same concentration of ESF present in the perfusate was incubated with either 0 8 per cent sodium chloride solution or red blood cell Ringer's solution and kept for the duration of the experiment in the perfusion chamber at 38° C (Table 1, groups 2, 5, 9)

Samples from the perfusate and the controls were tested by bioassay in rats by the method of Hodgson *et al* [8] Fasting rats were used and on the third and fourth day of fasting they were injected with aliquots of the supernatant of the perfusate and killed on the fifth day. Three hours prior to death, iron-59 (0 1 μc /rat) previously incubated with homologous plasma was given intravenously Blood, tibiæ, spleen and liver were removed, processed and counted in a well-type scintillation counter.

It is clearly shown that there are no differences in ESF activity between the samples obtained after perfusion and the controls incubated with either Ringer's or saline solutions. The validity of the assay is demonstrated by the difference between the control without added ESF and the control to which ESF has been added

If the estimated biological half-life of ESF is 8 h and if the liver had a role in the conjugation of this hormone, then certainly an effect should have been observed

Our results are not in agreement with the findings of Burke and Morse[4] It must be noted that in their experiments blood with a high endogenous titre of ESF was used as perfusate, whereas in the present experiments ESF was added to the red blood cell Ringer's mixture

On the basis of these findings, it is concluded that exogenous ESF is not inactivated by the perfused rat liver The reasons for the differences between the behaviour of endogenous and exogenous ESF are not apparent

Electrophoretic Patterns of *Macaca mulatta* and *Macaca nemestrina* Hybrid Hæmoglobin

VARIATIONS in the electrophoretic mobilities of hæmoglobin have been described in many species of sub-human primates[1–6]. A colony of 524 *Macaca mulatta* and 13 *Macaca nemestrina* was surveyed for hæmoglobin types by filter paper electrophoresis Two animals within the group had physical characteristics which combined features of both *M. mulatta* and *M nemestrina* These animals were purchased from the Miami Rare Bird Farm, Kendall, Florida, as part of a group of *M nemestrina*

Capillary blood of all animals was used for determination of the hæmoglobin type using 0 0125 M veronal buffer at *p*H 8 6 (ref 7) Venous blood was drawn from any animal with an abnormal pattern, and the method adopting 0 019 M barbital buffer at *p*H 8 6 was used[7]

The hæmoglobin of *M. mulatta* had the electrophoretic mobility characteristic of human hæmoglobin type A (refs 3 and 4), while the mobility of the hæmoglobin of *M nemestrina* was distinctly greater No variation within either group could be detected The hæmoglobin patterns of the suspected hybrids had both the slow component of the *M mulatta* and the more rapid component of the *M nemestrina* Fig 1 is a photograph of the electrophoretic patterns obtained from three representative animals

A *M. nemestrina* female and a *M mulatta* male were mated in the laboratory, and a premature, but viable, hybrid was obtained This animal had a hæmoglobin pattern the same as that of the two suspected hybrids Both the suspected hybrids were females and both had been mated successfully, one to a *M mulatta* and the other to a *M nemestrina*

It is of interest that the hybridization of the two species occurs readily in the laboratory, and it might be suspected

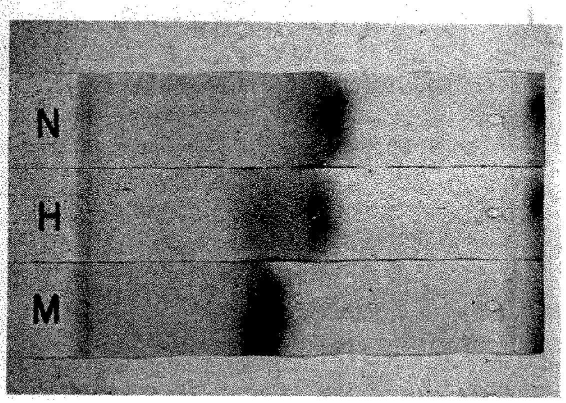

Fig. 1. Electrophoretic patterns of hæmoglobins of : (*N*) *Macaca nemestrina*; (*H*) hybrid; (*M*) *Macaca mulatta*

that the two females which were purchased were the results of natural or unplanned interspecific mating. The desirability of producing a hybrid between species of primates was pointed out by Jacob and Tappen[2]. Investigations of hybrids would help to elucidate the genetic mechanism of hæmoglobin transmission. At the present time, the difference between the hæmoglobins of the two species is used for measuring the viability of bone marrow transplants in irradiated animals.

Acetylcholinesterase Inactivation of Enzyme-treated Erythrocytes

THE molecular architecture of the red cell membrane formed mainly by lipids and proteins is not known; but it is possible to obtain information about its surface structure with the aid of agents which act on components located at the outer surface of the erythrocyte. This approach has been used to show the role of sialic acids in the electrokinetic behaviour of erythrocytes in an electrolyte medium[1].

Treatment of red cells with proteolytic enzymes has been widely used in blood-grouping techniques since Morton and Pickles[2] made the observation that trypsinized erythrocytes were agglutinated in saline suspension by incomplete Rh antibodies. However, the mechanism by which these enzymes exert their serological effect is not understood, although it has been demonstrated that this kind of treatment causes decrease in the electrophoretic mobility of erythrocytes[1], associated with the release of *N*-acylated neuraminic acid-containing mucoids[1], destruction of various blood group receptors[3], reduction of *in vivo* survival[4] and lysis in response to *p*H changes[5]. Prager *et al.*[6] have demonstrated that diisopropyl phosphoryl trypsin and *p*-chloromercuribenzoate-inactivated papain were bound to the red cell surface but did not possess any serological effect, therefore suggesting that the proteins must act enzymatically in order to affect agglutination.

Among the few enzymes recognized in the red cell membrane, acetylcholinesterase is one of the most investigated and previous studies have shown that the activity of this enzyme is reduced in new-borns affected with ABO hæmolytic disease[7]. A similar defect has been described in erythrocytes of patients with paroxysmal nocturnal hæmoglobinuria[8] and one of the features of this disease is the hæmolysis caused by acidified normal serum. Yachnin *et al.*[5] have shown that normal erythrocytes were made susceptible to lysis in response to changes in *p*H, by treatment with proteolytic enzymes, neuraminidase or sodium periodate; however, the effect of these agents on the red cell acetylcholinesterase was not examined. This communication gives the results of such an investigation.

Blood obtained from normal adult individuals was centrifuged and the erythrocytes washed 3 times with 20 volumes of 0·15 M sodium chloride solution. To one volume of packed cells, four volumes of buffered enzyme solution prepared according to Morton[9] were added and incubated for 30 min at 37° C. Cells incubated with buffer were used as controls. At the end of the incubation period cells were washed 3 times with ice-cold saline and a 50 per cent cell suspension was prepared. No noticeable hæmolysis was observed during the manipulation of the cells. Measurements of acetylcholinesterase activity were performed with the acetylthiocholine method[10].

Table 1. ERYTHROCYTE ACETYLCHOLINESTERASE INACTIVATION BY PROTEOLYTIC ENZYMES

§ Gift from Dr. G. L. Ada, Melbourne, Australia.

Table 1 indicates the percentage of inactivation of acetylcholinesterase of intact erythrocytes as compared with the controls incubated with buffer, and it can be noticed that the concentrations of proteolytic enzymes correspond to those routinely used in the detection of incomplete antibodies. When red cell ghosts, prepared by osmotically induced hæmolysis or by freeze-thawing, were incubated with proteases a similar inactivation of the enzyme was observed. From experiments in which solubilized acetylcholinesterase was mixed with trypsin and initial rates measured for 2 min or when trypsin was added at various time intervals to complete assay systems, it was possible to infer that this proteolytic enzyme did not interfere with the measurement of the acetylcholinesterase activity. This possibility was also ruled out when the activity was measured by a modification of the electrometric method of Michel[11]. No significant acetylcholinesterase activity could be detected in the supernatant solution after enzymatic treatment.

Studies of the time course of the enzymatic acetylcholinesterase inactivation over a 60-min period at 37° C revealed an exponential loss of activity with first-order kinetics, as can be observed from Fig. 1. This observation is compatible with the indication that proteases do not act merely by binding to the red cell membrane but by an active proteolytic process. In experiments in which red cells were agglutinated with their ABO iso-antibodies, no protection against proteolytic inactivation of acetylcholinesterase could be detected. Treatment of erythrocytes for 24 h with highly purified cholera vibrio neuraminidase[12] did not inactivate acetylcholinesterase, suggesting that *N*-acetyl neuraminic acid, an integral part of the human erythrocyte surface, was not associated with

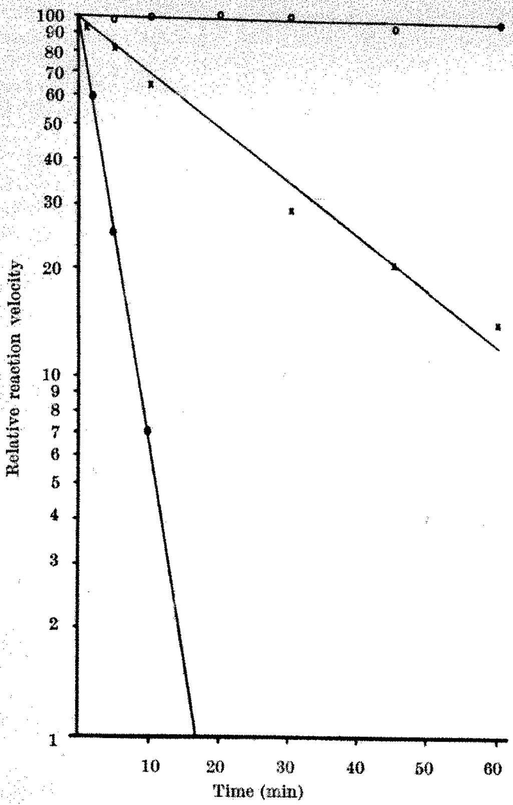

Fig. 1. Effect of time and concentration on erythrocyte acetylcholinesterase inactivation by bromelin. To 0·1 ml. of a 50 per cent cell suspension 0·4 ml. of bromelin in 0·1 M phosphate buffer, *p*H 6·0, was added, tubes incubated at 37° C for time indicated, immediately washed three times with 20 vol. ice-cold 0·15 M sodium chloride solution and stored as 50 per cent cell suspension at 4° C. Activity was measured as indicated in text. ○, 0·1 mg/ml.; ×, 1 mg/ml.; ●, 10 mg/ml.

the activity of the enzyme. Lysozyme and lipase (10 mg/ml.) were equally ineffective.

The activity of intracellularly located enzymes, such as lactic dehydrogenase, glucose-6-phosphate dehydrogenase, acid phosphatase and inorganic pyrophosphatase as well as the stromal enzymes alkaline phosphatase and adenosine triphosphatase, was not affected by treatment of whole red cells with proteolytic enzymes.

This work was supported by grant *AM*–01387–07 from the National Institute of Arthritis and Metabolic Diseases of the National Institutes of Health, U.S. Public Health Service.

Note added in proof. Since this paper was submitted for publication, Firkin *et al.* (*Australasian Ann. Med.*, **12**, 26; 1963) have reported acetylcholinesterase inactivation by trypsin and chymotrypsin.

PATHOLOGY

Streptokinase and Buerger's Disease

BUERGER originally described thromboangiitis obliterans as primarily a thrombotic process occurring in arteries and veins[1]; later he postulated that the thrombosis arose from an angiitis[2]. Impressed with the thrombotic aspects of the disease, our laboratory undertook an investigation of clot formation and dissolution in Buerger's disease. Clots obtained from patients diagnosed as suffering from Buerger's disease were exposed to varying concentrations of streptokinase ('Varidase'; Lederle Laboratories) as were clots obtained from normal patients. While the blood clots obtained from normal patients were found to be resistant to high concentrations of streptokinase, similar concentrations of streptokinase completely dissolved the clots obtained from cases with thromboangiitis obliterans

In recent years the entire concept of thromboangiitis obliterans as an entity has come under attack[3]. The findings described here would lend support to the concept of considering Buerger's disease a distinct entity.

Seven male patients (aged 36–46; average, 42), who had previously had amputations for thromboangiitis obliterans, were evaluated; none of these cases was in an acute phase of the disease. Only two cases had had an amputation within one year of the time of the investigation; the others had had an amputation 1–16 years previously.

Fifty-nine controls were used consisting of 28 normal individuals with an average age of 35 and 31 patients admitted to the hospital for various states of disease. The average age of the patient controls was 54 years. Of the 31 patients, there were six patients who had undergone lower extremity amputations for atherosclerosis.

The method of testing was as follows: Tubes containing concentrations of streptokinase beginning at 100 units and increasing to 2,500 units were prepared; 1 c.c. of freshly drawn patient's blood was then added to each test tube. The volume was kept constant. The blood and streptokinase were mixed and then allowed to remain undisturbed for 20 min, during which time clotting occurred. Afterwards the tubes were incubated at 37° C for 70 min. Thus a total of 90 min elapsed from the time of collection of the blood sample until completion of the test. Each clot was observed for the length of time necessary for complete lysis; however, if this did not occur during the 70 min of incubation, no further observations were made.

It was found that 50 per cent of the control clots ceased to lyse when the concentration of streptokinase reached 1,500 units. None of the control clots lysed when exposed

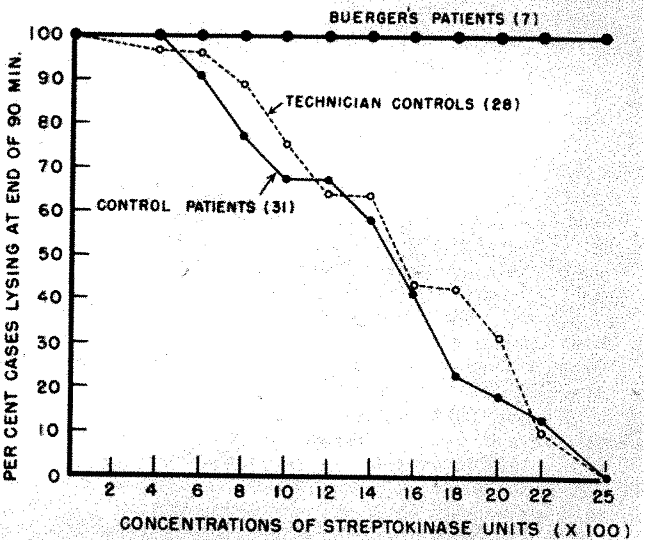

Fig. 1. Percentage of cases lysing their clots at the end of 90 min plotted against increasing concentrations of streptokinase

to 2,500 units of streptokinase for 70 min of incubation. The clots of all seven cases of thromboangiitis obliterans lysed when exposed to 2,500 units of streptokinase in less than 90 min (Fig. 1).

That streptokinase has an optimal concentration for fibrinolysis has been known but not adequately explained. The possibility of an inhibitor preventing clot lysis at higher concentration has been suggested[4]. Investigations are being carried out to explain further this mechanism in the normal individual and the difference noted in cases of Buerger's disease. The unusual behaviour of blood clots obtained from cases of thromboangiitis obliterans suggests that an abnormality in clot formation or lysis may be the ætiological factor in Buerger's disease.

Lactic Dehydrogenase in *L*1210 Cells

PROMPTED by the striking difference in lactic dehydrogenase activity observed by Woodliff[1] in sensitive *L*1210 leukæmic cells compared with those resistant to amethopterin and 6-mercaptopurine we have examined lactic dehydrogenase-levels in sensitive *L*1210*Z* and a strain (*L*1210*C*59) resistant to both amethopterin and 6-mercaptopurine and partially resistant to cytoxan.

Tumour-bearing mice were kindly supplied by Dr. A. Goldin and Mr. S. R. Humphreys and maintained as already described[2]. The mice used were $B6D2F_1$ ($C57BL/6J$♀ × $DBA/2J$♂). Local tumours (average weight 250 mg) from the site of injection and infiltrated spleens (500 mg, 5 times normal weight) were removed 9–12 days after inoculation and stored at – 15° two weeks prior to preparation of the enzyme extracts. These extracts were prepared by homogenizing the tissues in 3 volumes of chilled 0·1 M sodium phosphate buffer, *p*H 7·0, followed by centrifugation at 60,000*g* for 30 min. Protein content was measured spectrophotometrically[3].

Each 1-ml. incubation contained DPNH 0·00013 M, sodium pyruvate 0·002 M, sodium phosphate, *p*H 7·0, 0·1 M, and 14 μg protein; read in a Beckman *DU* spectrophotometer at 32°. The Δ absorbance for a control incubated without pyruvate was 0·004/min.

As shown in Table 1, we could reveal no difference in lactic dehydrogenase activity in extracts of sensitive and resistant cells.

Table 1. LACTIC DEHYDROGENASE IN TUMOUR CELL EXTRACTS

	Initial Δ absorbance/min (340 mμ)
Sensitive local tumour	0·062
Resistant local tumour	0·058
Sensitive spleen	0·052
Resistant spleen	0·052

Extracts of local tumours have been analysed by starch electrophoresis[4] by Dr. L. A. Costello of Brandeis University and shown to be predominantly the muscle (*M*) type. Heart (*H*) type was barely detectable. M_3H_1, M_2H_2, M_1H_3 were present in trace amounts which decreased in the order named. There was no difference in the pattern obtained from sensitive or resistant cells.

The difference between our results and those of Woodliff may be explained by: (1) different strains of tumour were used; (2) Woodliff used the ascites form of the tumour; (3) the cytochemical technique used by Woodliff to measure lactic dehydrogenase may reveal a difference in staining properties of the cells unrelated to the amount of enzyme present.

We conclude that lactic dehydrogenase in extracts of the drug-sensitive and drug-resistant *L*1210 cells examined is quantitatively and qualitatively the same.

Distribution of Endogenous and Parenterally Administered Porphyrin in Viable and Necrotic Portions of a Transplantable Tumour

TETRAPHENYLPORPHINESULPHONATE (TPPS) is a synthetic, non-naturally occurring porphine derivative which accumulates to a greater extent in the tumours than in the other tissues of tumour-bearing rats after parenteral administration[1]. Because of its optical and solubility properties it can be differentiated from, and analysed in the presence of, endogenous porphyrin. These properties made possible quantitative study of two aspects of the tumour localization of porphyrin that had been seen grossly with other parenterally administered porphyrine: the greater apparent accumulation in the necrotic portions of the tumours[2,3], and the absence of apparent red fluorescence in some tissues despite high porphyrin concentrations[4].

Quantitative analyses of endogenous porphyrin and TPPS were done by an extraction procedure and spectrophotometric assay developed for this purpose and described previously[1]. This assay utilizes the complete separation of the major absorption peak of TPPS at 438 mμ from that of endogenous porphyrin at 407 mμ in dilute acid. Three zones of the Walker carcinosarcoma 256, grown 18 days, were separated by dissection: (1) sub-capsular tissue, comprising about 2 mm depth from the surface; (2) viable tissue of a homogeneous grey-white colour; (3) non-hæmorrhagic necrotic zone in which small discrete, pearly white areas, identified histologically as regions of necrosis, merge towards the centre of the tumour.

In Table 1 is shown the distribution of endogenous porphyrin in the three zones of control tumours, and of TPPS in tumours from rats that received 5·0 mg TPPS intravenously 24 h before killing. The concentration of TPPS was considerably higher than that of the endogenous porphyrin in all zones of the tumour. TPPS was most highly concentrated in the necrotic area, as was the endogenous porphyrin. TPPS concentration in the viable portion of tumour was also high, while that of the endogenous porphyrin was low, about that found in 12-day-old non-necrotic tumours[5]. The difference between

Table 1. ENDOGENOUS PORPHYRIN AND TPPS IN SUB-CAPSULAR VIABLE AND NECROTIC ZONES OF WALKER 256 CARCINOSARCOMA

		Control (6 animals) mg endogenous porphyrin*/gm net weight	Experimental (6 animals) mg TPPS/g net weight
Sub-capsular	mean ± *S.D.*	5·6 ± 3·3	22·5 ± 5·9
Viable	mean ± *S.D.*	2·3 ± 1·7	34·5 ± 10·6
Necrotic	mean ± *S.D.*	16·0 ± 6·3	52·1 ± 13·8

*Calculated on the basis of $\left(E_{1\,\text{cm.}}^{1\%}\right) = 4\cdot9 \times 10^3$ (ref. 6)

TPPS concentration in viable and sub-capsular zones is not marked.

The finding that the parenterally administered TPPS and the spontaneously appearing endogenous porphyrin were both most concentrated in the necrotic zone suggests that they may both be accumulated from the circulation rather than endogenous porphyrin having arisen *in situ* from broken-down hæm. The high concentration of TPPS and the low concentration of endogenous porphyrin in the viable portion of the tumour represent the major difference in the pattern of their distribution. While there was no significant removal of endogenous porphyrin from the circulation into the viable portion of these tumours, such a mechanism could explain the concentration of parenterally administered hæmatoporphyrin[5], as well as the spontaneous accumulation of natural porphyrins that is known to occur in non-necrotic tumours and in the viable portion of necrotic tumours.

The far greater apparent fluorescence of the necrotic portions seemed out of proportion to the differences in TPPS concentration found on analysis. This is seen in Fig. 1, which shows the appearance under ultra-violet light of a tumour which grew for 24 days. The rat received 5 mg TPPS 24 h before killing. The brightest fluorescence occurred in the discrete, pearly white, necrotic foci that merge towards a central area of hæmorrhagic necrosis in which no fluorescence is apparent. In control tumours of this age a faint red fluorescence was seen in areas of non-hæmorrhagic necrosis.

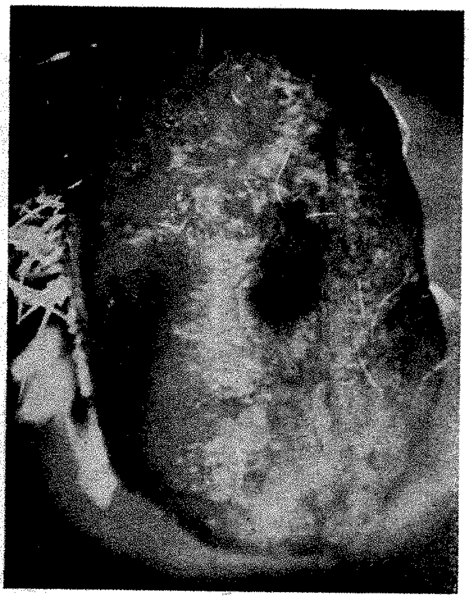

Fig. 1. Black-and-white reproduction of the colour photograph taken under ultra-violet light of the cut surface of the Walker-256 carcinosarcoma. White areas represent red fluorescing areas in the original

We have found that the liver, spleen and kidney exhibit no red fluorescence despite TPPS concentrations as high as 39 μg/g, while much lower concentrations conferred brilliant red fluorescence on tumours, and especially their non-hæmorrhagic areas. The same effect occurred when TPPS was added to whole homogenates and 100,000 × g supernatant solutions of these tissues. Blood was shown to act as a non-fluorescent absorber of the wave-lengths that excite TPPS fluorescence. Decreasing the excitation path-length increased the instrumentally measurable fluorescence, and in the limiting case of zero path-length, quantitative measurement of TPPS can be made even in turbid homogenates of liver, spleen and kidney from the fluorescent emission of the surface of the cuvette[1]. The redder the tissue, the less apparent was the red fluorescence visually. A possible explanation of this is that the filtered ultra-violet light used contained some red light for which the redder tissues have a higher reflectivity than do the less red ones; thus, the observer must make a small intensity discrimination rather than a definite hue discrimination.

These effects may account in part for the emphasis placed on the concentration of porphyrin in necrotic portions of tumours which arose from estimation of relative tissue concentration on the basis of visible red fluorescence.

GERONTOLOGY

Age Differences in Choice Reaction Time and Cardio-vascular Status among Pilots

ATTENTION has recently been directed to the conflict of evidence existing in those data on sensory-motor performance in relation to age to which the mathematics of information theory could be reasonably expected to apply in a straightforward manner[1]. Specifically, in the formula for choice reactions[2]: $RT = a + b \log_2 n$ (where n is the number of equivalent choices), the well-known slowing of response with age is sometimes reported as an increase in the constant a, and at other times as a rise in b. In an attempt to resolve these contradictory data on choice, discrimination and movement times, it has been suggested that the effective duration of signals may determine the outcome, producing an increase with age in the intercept when signals are brief, but an increase of the slope when they are relatively long. Whereas the latter result leads logically to interpretations in terms of reduced 'channel capacity' with age, the former has prompted speculations about the possibility of a change in the level of 'neural noise'[3,4]. These ideas derive from the statistical theory of signal detection[5], and as compared with classical psychophysics, their novelty consists in postulating that the brain is a rather 'noisy' communication channel, so that a decision about sensory input is based on information in some way distorted by random neural activity within the central nervous system itself. Hence, the decision mechanism must 'test hypotheses', so to speak, to distinguish between the states of 'noise alone' and 'noise plus signal'. Yet, apart from emphasizing that the latency of a response must be mainly due to the time necessary to collect a statistically reliable sample for a correct decision, it is not clear what properties of the channel are being specified by either type of theory.

Work in progress here may eventually throw some light on this dilemma. Preliminary results, obtained from some four-dozen commercial, military and test pilots, ranging in age from the twenties to the sixties, reveal several interesting trends in performance at a conventional choice reaction task under conditions of what one might call 'information overload'. The aim is to gauge 'spare channel capacity' by the introduction of subsidiary tasks and measurement of their effects on performance of the main task[6,7]. The rationale of this approach is two-fold. In the first place, one must assume that any realistic estimate of the total mental load on the pilot cannot be based solely on observation of what he is doing at any particular moment during the execution of his skill, but must also take into account all other possible decisions which he might have to make at very short notice[8–10] In the second place, it should be borne in mind that the human operator of modern control systems, particularly in aviation, has become progressively less concerned with continuous manual monitoring and more and more concerned with the interpretation of a large variety of signals for action, which may originate from different sources simultaneously or in rapid succession[8,10] In so far as control in this sense must involve transfer of information, the emphasis is then on continuous readiness for quite complex judgements and decisions, many of which have to be made within very restricted time limits if they are not to become antiquated in relation to a rapidly changing display To the extent that a decision preceding any action is the choice of one from a set of alternatives, certain average properties of choices, such as the increase in response latency with increase in input entropy, become relevant in this context, since they must, in some sense, reflect the 'channel capacity', that is, the rate at which the brain can gain information[2]

The basic situation is the familiar one in which the subject is presented with a sequence of signals, visual and auditory, is required to identify them and then to operate some appropriate control with the maximum of speed and minimum of error The inter-signal intervals vary randomly between 0 5 sec and 5 sec, in runs of some 300 in length, each signal having an equal probability of occurrence in ensembles of three, five and eight alternatives, so that at any moment the subject is uncertain which signal is likely to occur and when A detailed record of response latencies, in msec, and of error rates is obtained on the *Setar*[11] and further quantitative analysis carried out with the aid of a Bendix *G*-15 computer The subsidiary tasks utilized are of two main types, with certain variations on each theme

(1) A short-term memory sub-task, which requires the subject to watch a succession of symbols projected on to the centre of the main display, and to recall the symbol presented two stages earlier, single symbols, letters and numbers, or pairs of symbols are used, the presentation lasting in each case some 4 sec, the subject may be asked for recall each time the display changes, or only on certain occasions, on the receipt of a verbal command, also he may be required to carry out both the main and the subsidiary tasks under 4-c/s flicker exposure (this extension constituting an attempt to investigate the possible effects of 'flicker-vertigo'),

(2) The other type of subsidiary task requires the subject, in addition to executing the manual responses in the main task, to 'name' each signal by three very simple code words, describing the successive characteristics of display and control, something approaching a 'stress' situation is imposed by arranging for a delay of 0 18 sec in the auditory monitoring of the subject's speech[12]

In addition, the cardio-vascular system of each individual participating in the investigation is subjected (by Dr R Proper, of the Lovelace Clinic) to a very detailed assessment based on ballistocardiogram stroke volume, plethysmograph and pulse-wave velocity, recorded before and after exercise[13]

It will be seen from Table 1 that, dividing the sample at the age of forty, the average rates of gain of information range from just over five to just over four for the younger group, and from just under five to just under four binary decisions per second for the older group It should be noted that at these rates greater than 95 per cent accuracy is maintained in the basic task, after some preliminary practice, and only about 10 per cent error is made in the subsidiary tasks It is clear from the data that the principal differences between the two age groups are to be found in the values of the constant *a* There is no evidence of any substantial reduction in rate with age until the subjects' maximum capacity is reached under conditions of information overload It is only then, particularly with the short-term memory sub-task, and less so with delayed auditory feedback in the verbal sub-task, that the slope constants show any increase (There is also some evidence in the data, suggestive rather than conclusive that the central refractory phase may be lengthened when the memory task is added to the main choice reaction A suitable technique for more detailed recording is being developed) Even so, the amount of this increase is far from being impressive and basically the curves are displaced upward, changing the intercept *a* Furthermore, amplifying the background stimulation by exposure to intermittent flashes of light when the memory task is attempted seems to reduce the slope, without however, in the case of older subjects, lowering the intercept (attenuating the 'noise'-level?) This finding is in line with some of the results of central refractoriness[14,15]

It is of interest that a trend in the combined cardiovascular and psychological data can also be discerned Ranking the efficiency of cardiac output and the magnitude of reduction in the speed of decision under conditions of information overload, a negative correlation $\tau = 0\ 518$ is obtained, and found to be significant at better than $p = 0\ 001$ level (the normal deviate value is 4 08) (ref 16)

If these essentially preliminary results of an investigation still in progress can be accepted at their face value, they suggest that

(*a*) In a sample of individuals representing the profession of piloting aircraft, the practice of which requires making high-speed decisions, age differences in the rate of gain of information are less impressive than might be expected from other data in the field of gerontology[17] This raises once again the question of occupational transfer effects in investigations of ageing and suggests that investigators should be cautioned to test those primary skills which constitute the over-learned repertoire of adult professional life[18]

(*b*) Pilots over 40 years of age are relatively more susceptible than the younger to the effects of information overload particularly if this involves short-term recall when some other activity intervenes during the period of retention It is not clear, however, whether the conclusion that, to this extent, they may be said to possess less 'spare mental capacity' than the young is really forced on us by the data The paramount difficulty is still that of deciding on an appropriate measure of loss In so far as skill proficiency can be gauged outside the flying situation itself, the routine aspects of their skill are, on the present evidence, unlikely to be affected by ageing However, their responses to sudden emergencies under conditions of information overload may conceivably be expected to become less adequate as they grow older Needless to say, further research is needed to discover the limits within which these assumptions are justifiable

Table 1 REGRESSION ANALYSIS OF INDIVIDUAL PERFORMANCE RECORDS RESPONSE TIME (RT) $= a + b \log_2 n$ MEAN VALUES OF THE INTERCEPT AND SLOPE CONSTANTS PER SUBJECT ($t(b) = t$ TEST ON THE SLOPE CONSTANT)

	Younger Group (Range 20–39, mean age 31 4) $N = 25$	Older Group (Range 40–67, mean age 48 8) $N = 23$
Main Choice Reaction Task Alone	$RT = 0\ 233 + 0\ 090 \log_2 n$ $t(b) = 11\ 27$ Rate $= 5\ 15$ bits/sec	$RT = 0\ 280 + 0\ 085 \log_2 n$ $t(b) = 10\ 26$ Rate $= 4\ 94$ bits/sec
With Short-Term Memory Sub-Task	$RT = 0\ 368 + 0\ 086 \log_2 n$ $t(b) = 4\ 12$ Rate $= 4\ 17$ bits/sec	$RT = 0\ 430 + 0\ 099 \log_2 n$ $t(b) = 4\ 08$ Rate $= 3\ 69$ bits/sec
With Short-Term Memory Sub-Task and Under Flicker Exposure	$RT = 0\ 356 + 0\ 082 \log_2 n$ $t(b) = 4\ 81$ Rate $= 4\ 31$ bits/sec	$RT = 0\ 431 + 0\ 077 \log_2 n$ $t(b) = 4\ 01$ Rate $= 3\ 88$ bits/sec
With Verbal Sub-Task	$RT = 0\ 219 + 0\ 117 \log_2 n$ $t(b) = 11\ 41$ Rate $= 4\ 69$ bits/sec	$RT = 0\ 252 + 0\ 110 \log_2 n$ $t(b) = 9\ 21$ Rate $= 4\ 69$ bits/sec
With Verbal Sub-Task and Delayed Aural Monitoring of Speech	$RT = 0\ 260 + 0\ 105 \log_2 n$ $t(b) = 7\ 80$ Rate $= 4\ 71$ bits/sec	$RT = 0\ 299 + 0\ 117 \log_2 n$ $t(b) = 7\ 78$ Rate $= 4\ 18$ bits/sec

(c) Although the slowing with age, observed in the face of additional information challenge, is equivalent to reducing the rate of transmission of information, it does not unequivocally suggest a reduced capacity for discrimination and choice It may mean, for example, that the forms of encoding and decoding operations performed by the brain are adjusted to the characteristics of the available channel according to the nature of prevailing input and the weight assigned to other inputs Until more plausible theoretical conceptions are brought to bear on the problem at issue, the factor limiting decision and short-term storage processes among the older adults appears to be in the nature of an increased 'noise-level' in the central nervous system Moreover, assuming that the agreement between the findings from psychological and cardiovascular tests is not misleading, it is possible to speculate further that a reduced rate of cerebral blood flow may contribute to the hypothetical random activity in brain cells

RADIOBIOLOGY

Transmission of Ultra-violet Rays in Quartz Fibres

Ultra-violet rays cannot penetrate deeply into tissues, consequently, investigations of their biological effects have been limited to unicellular forms, cells in tissue culture, and the surface cells of organs and organisms In my apparatus designed for conducting ultra-violet photons to the deeper cells of the brain, penetration of the tissue is achieved with quartz fibres which act as conductors for the energies under consideration

These quartz fibres are made by heating a small section of a clear fused quartz rod 4 mm in diameter in the hottest part of a gas-oxygen flame When the quartz becomes white hot, it is pulled into a fibre as it is moved into the cooler part of the flame The fibre is then broken Each resulting piece of quartz has a large end, which is equal in diameter to the original rod, a tapering portion about 10 mm long, and a terminal fibre 10–40 mm long With a little practice, one can make fibres having tips less than 10μ in diameter The tip of the fibre can be pushed into the brain of a chick embryo with comparatively little disruption of the tissue

The large end of the quartz rod is fixed in a hole in the housing of a low-pressure mercury arc lamp, a source which emits much of its energy at 2537 Å The behaviour of ultra-violet photons is observed by placing the rod and its terminal fibre next to the concave surface of a fragment from an ordinary fluorescent lighting tube The phosphor contained on the inner surface displays a white fluorescence when it absorbs photons in the 2537 Å line Transmission of these photons is demonstrated by placing a filter between the mercury arc source and the large end of the rod, the filter transmits the 2537 Å line plus some blue light Using micromanipulation apparatus, the fibre is brought into contact with the phosphor Under magnification, the blue light visible in the fibre is readily distinguished from the whole light which indicates excitation of the phosphor

Most of the rays which enter the quartz escape from it in the tapering portion; although their angle of incidence on the quartz-air interface is greater than the critical angle for ultra-violet in these media, repeated internal reflexion rapidly reduces this angle of incidence Some of the rays, however, enter the terminal fibre, and are conducted to its tip The emerging cone of energy is fairly well collimated after its passage through the fibre, and its physical effects can be delineated

Hinrichs[1–3] and Hinrichs and Warrick[4] used a pointed quartz rod to direct radiation from a mercury arc against small surface areas of chick embryos and fundulus hearts It is possible that much of the energy conducted in their rods was in the ultra-violet range It must be pointed out, however, that a fair amount of radiant heat is emitted by a mercury arc lamp, such energy is conducted in quartz by internal reflexion, and may have caused the damage observed by Hinrichs and Warrick in the target tissues Using a suitable phosphor as a target, it is possible to demonstrate the transmission of ultra-violet rays in quartz fibres

Multiple Anomalies occurring in a New-born Spanish Goat following Prenatal Gamma-radiation

A unique and complex combination of abnormalities occurred in a Spanish goat (genus *Capra*) following prenatal irradiation The dam, a vigorous 3-year-old, was subjected to radiation from a cobalt-60 source[1] on the 30th day of pregnancy Dosage was 300 r administered at 100 r /h

Following a normal gestation period of 150 days, the doe gave birth to a female kid weighing 4 3 lb Average weight for irradiated single kids in the flock was 5 2 lb

A number of aberrations were immediately apparent in the animal Functionally the most obvious was the animal's lack of muscular control and inability to rise or stand It was quite vigorous vocally and emitted sounds normal for its species and age The back was held in a rigid straight line, and all limbs were extended backward and parallel with the spinal column The head was drawn downward with the jaw near the chest, which gave a pronounced arched appearance to the neck

Table 1 ELECTROCARDIOGRAPHIC, ELECTROENCEPHALOGRAPHIC RESULTS AND RESPIRATORY RATE OF THREE GOATS

Animal and No	Electrocardiogram			Respiratory rate per min	Electroencephalogram
	Amplitude *QRS* complex (mV)	Amplitude *T* wave (mV)	Heart rate beats per min		
Irradiated abnormal No 27	1 11	0 37	180–240	77	High voltage, 2–4 c/s activity with some secondary waves
Irradiated apparently normal No 25	0 88	0 17	170	55	Low voltage, 8–12 c/s activity
Control No 26	0 66	0 18	170	40	Low voltage, 22–30 c/s activity

A number of morphological defects were apparent, the most obvious being a short, underdeveloped left foreleg and a rudimentary left forefoot There was microcephaly associated with a short upper jaw and a deviation of the mandible to the left There was also a cleft-palate condition and the left ear was shortened The eyes were defective with anophthalmia on the left and microphthalmia on the right associated with a narrow iris In addition to the defects already noted, X-ray observations revealed an underdeveloped left scapula and a prominent dorsal arching of the thoracic spinal column with apex most pronounced at the sixth vertebra

Nourishment of the animal presented a problem For the first three days of life it was held to the mother's nipple, and milk was expressed by hand into its mouth It was apparently unable to suckle because of the cleft palate and deformed mouth A bottle-feeding routine was adopted, utilizing milk obtained from the kid's mother The animal initially lost weight, weighing only 3 8 lb on the 4th day of life Successive weights were as follows 13th day 4 4 lb , 21st day 4 9 lb , and on the 30th day 5 6 lb At six days of age it was able to hold its head erect, and a few days later was able to rise on its hind legs, but could never rise on its hind legs and hold its head erect simultaneously At no time was it able to obtain co-ordinated muscular control The goat preferred to lie on its right side When turned on the left side it usually became very excited and regained right-side posture by violent movements of limbs and head Before death the animal developed a mild diarrhœa It died from pneumonia on the 34th day of life

Clinical and physiological examinations showed rectal temperature slightly above normal, ranging from 104 0° to 104 6° F At 30 days of age the white blood cell count was 12,500/mm^3, the red blood cell count was 13×10^6/mm^3, hæmoglobin was 8 gm/100 ml and hæmatocrit was 25 6 per cent , all these values were within the normal range for young goats Heart rate varied from 180 to 240 per min Respiratory rates varied from 40 to 75 per min The pupil of the microphthalmic eye did not react to light , however, injection of atropine caused wide dilatation after 20 min The eyelids of the absent left eye responded to touch The animal would not respond to acoustic stimuli, but would respond to vibrations such as those produced by persons walking in the area

Recordings of electrocardiograms, electroencephalograms and pneumographs of the abnormal individual plus those of an apparently normal kid (irradiated with 300 r on day 30 *in utero*) and of a control kid (all born on January 2, 1963) show widely dissimilar results (Table 1) Tachycardia, high amplitude of *QRS* complex and *T* wave of the electrocardiogram, and high voltage and slow frequency (2–4 c/s) of electroencephalogram waves were characteristic of responses in the abnormal goat (Table 1) Similar pathophysiological changes have been observed following the administration of massive doses of mixed neutrons and γ-radiation of the goat[2]

Gross necropsy disclosed normal conditions in the thymus, heart, liver, thyroid, parathyroids, spleen, trachea, genito-urinary and alimentary tracts The alveolar membrane and alveoli of the diaphragmatic lobe of the right lung were filled with fluid and cells from a pneumonic condition Dissection of the forelimbs disclosed an underdeveloped left scapula, humerus, radius and ulna, the latter having no articular surface at the carpal extremity, and two fragmentary phalanges Total overall length of forelimbs (eliminating ulna) were left, 19 8 cm, right, 40 4 cm

Lack of critical irradiation data in the goat plus the single abnormal individual in a total of 4 animals born to dams irradiated on the 30th day of pregnancy make difficult the evaluation of results obtained The possibility that these defects were not radiation induced cannot be ruled out, but each of the defects reported have been observed in rodents following acute prenatal irradiation. The results of numerous investigations[3–10] demonstrate that critical periods for induction of almost all irradiation-induced abnormalities in the rodent are short and specific In the rat for example, at 300 r acute X-irradiation, short upper jaw occurs from irradiation on day 10, anophthalmia and microphthalmia on day 11, cleft palate on days 12 to 14 and forefoot reduction on day 13, to cite a few examples of separate stages in which there is little or no overlap of critical periods[5] The animal cited in this report had numerous observed defects following a single 3 h period of irradiation totalling 300 r , the same as for the rats The effective period of irradiation disturbance is reported to be lengthened by raising the dose[4] As the dose in this case was quite large, having produced death in three of 18 pregnant females irradiated at various stages of pregnancy, and is larger than the developing rodent will usually tolerate, it may have contributed to the multiple anomalies The level chosen, however, produced low maternal and fœtal mortality in irradiated swine and cattle[11,12]

We thank Dr C W Banks for the radiographic analysis and Dr F W Mestanza for assistance in the post-mortem examination

BIOLOGY

Hydroxyproline as an Inhibitor of Auxin-induced Cell Elongation

AUXIN-INDUCED cell elongation can be inhibited by a variety of substances[1] Among these inhibitors are the amino-acid antagonists canavanine[2], β-2-thienylalanine[3] and ethionine[4,5] This has been taken as evidence that protein synthesis is necessary for cell elongation[6]. Recently, Steward *et al* [7] have presented evidence that hydroxy-L-proline can also be an amino-acid antagonist The growth of carrot callus explants could be blocked by this compound, and the inhibition could be completely reversed with L-proline Since growth in this tissue is largely due to cell division, an investigation has been undertaken into the effects of hydroxyproline on the elongation of *Avena* coleoptile sections in order to assess the effect of this compound on auxin-induced cell elongation

The following experimental procedure was used in this investigation 5-mm sections of 4-day-old *Avena* seedlings were obtained as detailed elsewhere[5] Lots of 10 sections were placed in 25 × 150 mm test-tubes containing 5 ml basal medium (0 0025 M potassium maleate at pH 4 8 + 2 per cent sucrose) When desired the solutions also contained indolyl-3-acetic acid (5 p p m) and hydroxy-L-proline at the desired concentration The tubes were then incubated on a 'Rollerdrum' in the dark After the desired length of time, the tubes were removed and the sections were measured with a microscope fitted with an eyepiece micrometer Each treatment was run in duplicate, each experiment was repeated at least three times

The effect of hydroxyproline on the elongation of *Avena* coleoptile sections during 24 h is shown in Table 1 Auxin-induced elongation was inhibited 50 per cent by 4×10^{-5} M hydroxyproline and almost 100 per cent by 10^{-3} M hydroxyproline The effect of 10^{-3} M hydroxyproline could be almost completely reversed by 10^{-3} M L-proline L-Proline itself has no effect on elongation These results indicate that hydroxy-L-proline is acting as an antagonist of proline metabolism in this system

Table 1 Effect of hydroxyproline on auxin-induced cell elongation All sections incubated 24 h in basal medium + 5 p p m indolyl-3-acetic acid and with L-hydroxyproline or L-proline at the concentration indicated

Concentration (M) L-Hydroxyproline	 L-Proline	% Elongation (24 h)
0	0	100
10^{-5}	0	99
10^{-4}	0	36
10^{-3}	0	20
10^{-3}	10^{-5}	38
10^{-3}	10^{-4}	90
10^{-3}	10^{-3}	97
Control (no auxin)		19

The time curve for the hydroxyproline inhibition is shown in Fig 1 It can be seen that hydroxyproline has no effect on cell elongation during the first 2–3 h Thereafter elongation is severely inhibited This lag in inhibition could be ascribed to two causes First, it might be a measure of the length of time needed for hydroxyproline to exert its inhibition Alternatively, the effect of this inhibition may only manifest itself after a certain amount of auxin-induced elongation has occurred Evidence to favour this latter possibility was obtained in the following manner Sections were placed in the basal medium containing 10^{-3} M hydroxyproline, auxin was added to groups of sections after 0, 6, 9, or 21 h, and the resulting elongation curves were determined It can be seen from Fig 2 that irrespective of the length of the hydroxyproline pretreatment, auxin elicited the same general response In each case sections showed rapid elongation for about 2 h Thereafter the elongation was inhibited such that the final rate of elongation was comparable to that of the non-auxin-treated control sections It is apparent that the ability of these sections to respond to auxin persists for at least 24 h after addition of hydroxyproline The magnitude of the elongation elicited decreased with increasing pretreatment with hydroxyproline However, this decrease is more likely due to the stiffening of the sections which occurs during periods of low elongation than to any specific effect of the hydroxyproline itself[8]

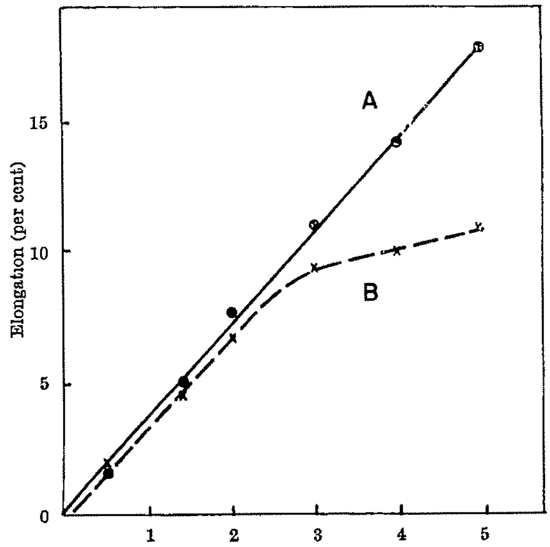

Fig 1 Time course of hydroxyproline inhibition Sections incubated in basal medium + 5 p p m indolyl-3-acetic acid and either with (*B*) or without (*A*) 10^{-3} M L-hydroxyproline

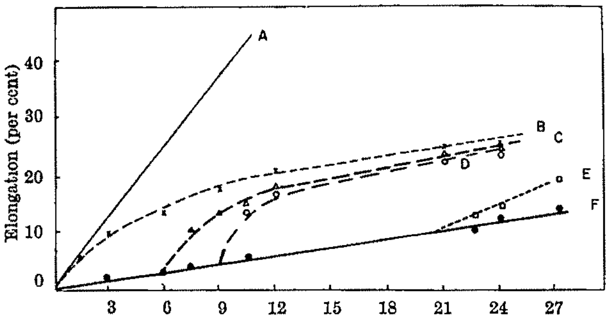

Fig 2 Effect of hydroxyproline pretreatment on auxin response Sections incubated in basal medium + 5 p p m indolyl-3-acetic acid (*A*) or + 10^{-3} M hydroxyproline (*B*–*F*) Indolyl-3-acetic acid (5 p p m) added after 0 h (*B*), 6 h (*C*), 9 h (*D*), 21 h (*E*) or not at all (*F*)

The manner in which hydroxyproline inhibits cell elongation is unknown, but there is ample reason to believe that it must interfere in some way with protein synthesis Other amino-acid antagonists act by either blocking protein synthesis[9] or by causing the formation of aberrant, inactive proteins[10] Furthermore, Steward *et al* [7] have cited evidence that hydroxyproline can prevent the incorporation of proline into proteins

The role of protein synthesis in auxin-induced cell elongation is still uncertain The fact that auxin is still able to induce cell elongation even after sections have been pretreated for 21 h with hydroxyproline suggests that protein synthesis is not required for the initiation of auxin-action Instead, the present results seem to favour the following picture Some product of protein synthesis is necessary for the actual process of rapid cell elongation This product becomes consumed during the cell elongation In normal circumstances it is being replenished by protein synthesis, but in the presence of hydroxyproline no new product is being formed Under these conditions elongation is limited by the amount of this substance In these sections the pool of this substance is sufficient to allow about 15 per cent elongation to occur This product of protein synthesis is stable for periods of up to 24 h This suggests that the substance is a protein itself rather than some secondary product such as ATP. This essential protein may be some enzyme which controls cell wall loosening and which is destroyed in the course of its action. Or it may be some structural cell wall protein, such as that reported by Lamport[11], which must be incorporated into the wall in order that continued elongation may occur. The effect of hydroxyproline on protein synthesis and the existence and nature of the essential product of protein synthesis are now under investigation.

Relationship of Relative Leaf Growth Rate to Net Assimilation Rate and its Relevance to the Physiological Analysis of Plant Yield

IN the growing plant, where the photosynthetic tissues make the major contribution to dry-matter production, the absolute growth rate at any time is the product of the rate of increase in weight per unit of leaf (net assimilation rate[1], N.A.R.) and the amount of leaf present. The latter is usually expressed in terms of leaf area, which is the product of leaf weight and the area-to-weight ratio.

The relative rate of increase in leaf weight (relative leaf growth rate—$R.L_W.G.R.$ expressed on a weight basis) may be increased either by an increase in N.A.R. or by an increase in the proportion of the products of assimilation which are devoted towards leaf growth. This does not seem to be widely appreciated, and the proportion of the products of assimilation going towards leaf growth is not generally calculated in growth analysis. This variable can be expressed as the ratio of $R.L_W.G.R.$ to N.A.R. and is most simply calculated for a time-interval t_1-----t_2 as $(L_{t_2} - L_{t_1})/(W_{t_2} - W_{t_1})$, where L refers to leaf weight and W refers to total weight; it is hereafter referred to as the leaf-to-total growth ratio L.T.G.R.

If plant growth is considered as a compound interest phenomenon[2] and the leaf area to leaf weight ratio to be constant, plant weight at any time would depend on the initial productive capital (leaf weight), the rate of interest on this capital (N.A.R. calculated on a leaf weight basis), the proportion of interest re-invested in productive capital (L.T.G.R.) and the period of time involved.

Leaf area/leaf weight is not, however, constant, and since area is probably a more useful measure of the amount of photosynthetic tissue than is weight, plant growth over its entire period must be considered to depend on: (*a*) the initial leaf area; (*b*) N.A.R. calculated on the basis of leaf area; (*c*) L.T.G.R.; (*d*) relationship of leaf area to leaf weight; (*e*) the length of the growing period.

It is clear, therefore, that the yield of crop plants can depend in large measure on the way in which the products of assimilation are allocated, that is, on the L.T.G.R. Thus the supply of nitrogenous fertilizer to cotton plants increases the relative leaf growth rate but not the net assimilation rate[3]; therefore, as Heath[4] pointed out, it increases the proportion of assimilate going to leaf, raising the ratio of leaf weight to total weight and consequently the relative growth rate. This treatment results in a large increase in leaf weight, in total weight, and in economic yield (seed cotton). It is, however, under conditions where the net assimilation rate and the relative leaf growth rate are varying in the same direction that it is of most value to calculate the L.T.G.R. in order to determine how much of the change in relative leaf growth rate and therefore in ultimate leafiness is in fact solely due to change in N.A.R.

The concept of L.T.G.R. is being used in a detailed investigation of the physiological basis of treatment effects on and seasonal variation in the yield of cotton which will be reported in detail elsewhere. This variable has also been calculated by Rees[5] working with oil palm.

Stomatal Distribution in Relation to Xeromorphy in Aquatic Plants

IT is well known that xeromorphy is of physiological importance[1] to the aquatic plants which exhibit it and certain tissues become altered in relation to environment. The modifications in internal leaf structure include a higher stomatal frequency. Limited enlargements of epidermal cells result in the increase in number of stomata per unit area. Though these are the features of a xerophyte, experimental evidences to show the stomatal distribution in relation to xeromorphy exhibited by an aquatic plant are meagre. In an attempt to elucidate the problem of xeromorphy in aquatic plants the wild species of *Ipomoea carnea* Jacq growing in different ecological habitats, that is, aquatic and xerophytic, was selected. The aquatic plants were selected from those growing at a 3–5 ft. depth of fresh-water in ponds and ditches and the xerophytic plants from those growing in the sandy soils of the plains. Though these plants belong to the same species they are not alike but have become adapted through generations of growth in the particular habitat. We consider that a comparison between the same species which has grown naturally under different ecological habitats might better contribute towards our understanding of the nature of xeromorphy than inducing xeromorphy under artificial conditions. The species considered here is a straggling shrub with milky juice and ovate-cordate leaves with large convolvulaceous pink flowers. The plant grows abundantly both in dry and marshy places besides its aquatic habit in various parts of India.

The healthy branches were selected from the plants growing under different habitats, leaves serially numbered from top to bottom and the stomatal counts were made after the nitric acid method as already described[2]. The area of the leaf was measured with a planimeter. Absolute stomatal number was determined by multiplying the average number of stomata per square mm of leaf area with the square mm area of the leaf. The results are expressed as percentages of that of the aquatic plant in Table 1 with respect to the absolute stomatal number and stomatal distribution per unit area.

The results indicate that when xeromorphy is exhibited by an aquatic plant, the absolute stomatal number increases 3–5-fold. There is a decrease in the ratio of absolute stomatal number between the upper to the lower surface of the leaf, as the leaf matures. A gradual shifting

Table 1. VALUE EXPRESSED AS PERCENTAGES OF THE RESPECTIVE LEAVES OF AQUATIC PLANTS

Leaf No.	Upper	Lower	Ratio upper/lower
(1) Absolute stomatal No.			
1	—	248	—
2	341	346	99
3	387	544	71
4	285	426	67
5	353	403	87
(2) No. of stomata per square mm leaf area			
1	—	148	—
2	138	145	95
3	99	141	70
4	99	120	82
5	106	115	92

in the formation of stomata to the lower leaf surface is a feature associated with xeromorphy. No significant change is observed on the upper leaf surface so far as stomatal distribution per unit area is concerned.

Reduced leaf lamina is a feature of aquatic plants, and in the species reported here the xeromorphic plants of the same aquatic species had four times the leaf area. Though leaf area was increased four times during xeromorphy, stomatal distribution per unit area was not changed on the upper leaf surface. However, there was a small but consistent increase on the lower leaf surface of the upper leaves, the increase being 41–48 per cent with respect to the same leaves of the aquatic plant.

Upper leaves, farther removed from water supply and exposed to high light intensity, are supposed to be more xeromorphic than the lower leaves of the same plant, and the results obtained in the present investigation suggest that xeromorphy when exhibited by an aquatic plant results in: (*a*) an increase in the absolute stomatal number; (*b*) increased stomatal distribution per unit area on the lower surfaces of leaves.

Occurrence of Indole Compounds containing Phosphorus in Etiolated Pea Seedlings

IN the course of paper chromatographic identification of compounds containing phosphorus-32 in different parts of plants the presence of phosphorus compounds with an indole skeleton seemed probable. To prove this, 10-day-old etiolated pea seedlings were kept for 24 h in the dark, in Knop's solution containing phosphorus-32 as KH_2PO_4 (the activity was 5 µc./ml.), and an alcoholic extract was chromatographed; on the start points of the one- and two-dimensional chromatograms an extract corresponding to 36 g fresh material was dropped. Developing was carried out first in isopropanol/ammonia/water, 10 : 1 : 1, and secondly in butanol/acetic acid/water, 4 : 1 : 5 solvent. The chromatograms were sprayed with Salkowski and Ehrlich reagent and exposed on X-ray film for 8 days. On the chromatograms prepared from the extract of epicotyls, five (Fig. 1), and on those prepared from the extract of roots, six, indole-positive spots appeared (Fig. 2): in both cases two of them proved to be radioactive.

In the case of the epicotyl, one of the two radioactive spots was found to correspond to the location and colour reaction of tryptophan, while in the case of the root to those of indolyl-3-acetic acid (IAA). The second radioactive spot gave in both cases a brick-red colour reaction with Ehrlich reagent.

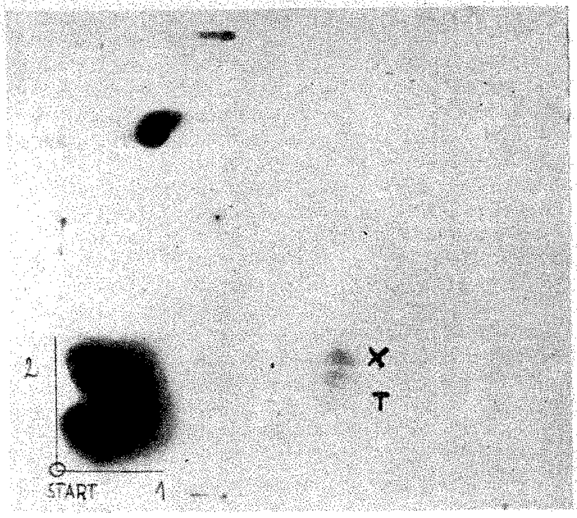

Fig. 1. Radiogram of compounds containing phosphorus-32 soluble in alcohol in the epicotyl of the etiolated pea. *T*, Tryptophan; *X*, unknown indole compound

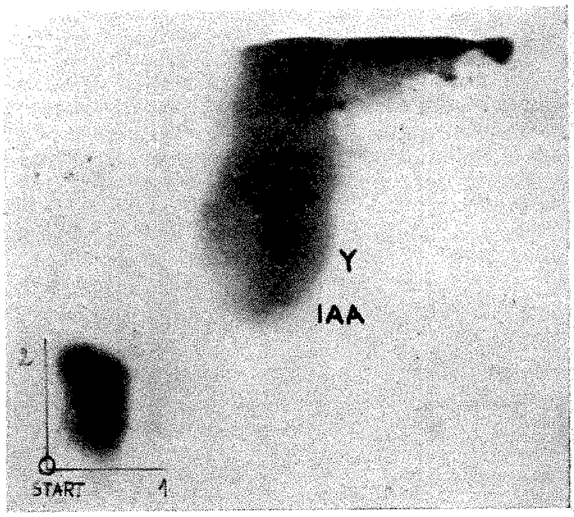

Fig. 2. Radiogram of compounds containing phosphorus-32 soluble in alcohol in the root of the pea. *IAA*, Indolyl-3-acetic acid; *Y*, unknown indole compound

Investigations are now being carried out to elucidate the structure and physiological importance of these compounds.

It may be assumed that the compounds involved are partly intermediary products of the biogenesis of IAA and the indole skeleton respectively[1,2] and, on the other hand, one of them is a compound of IAA formed with phosphoric acid playing a part in the growth regulator system in the plants. Our results, that an IAA derivative containing phosphorus is present in growing plants, is in accordance with the assumption of Rhodes and Ashworth[3] whereby the primary effect of IAA is based on the formation of energy-rich phosphate bonds.

Cytoplasmic Dimorphism within Pollen Grains

MATURE pollen grains contain a vegetative nucleus and either a generative nucleus or two sperm nuclei (derived by mitotic division of the generative nucleus). It has been generally accepted that the generative nucleus has an associated cytoplasm containing basic cell organelles[1,2] and is separated from the vegetative cell cytoplasm by plasma membranes. While Venema and Koopmans[3] have recently reported that a phase-contrast study of germinating pollen yielded no evidence for the 'bicellular'[4] nature of pollen grains, confirmation has been achieved by Safijovska[2] utilizing light microscopy, and in a definitive manner in the electron microscopic examination reported by Bopp-Hassenkamp[5]. In addition to demonstrating the presence of a generative cell, the investigation by Bopp-Hassenkamp indicated that vegetative and generative cell cytoplasms differ in relative organelle numbers, and to a degree in organelle morphologies as seen in profile. Safijovska has observed that generative cell cytoplasm is longer-lived than vegetative cell cytoplasm in both aged pollen tubes and following pollen tube rupture. A comparative investigation of the fine structure of pollen cytoplasm now being conducted by me has made possible the observation of generative cells within pollen grains of a number of plant species.

Mature pollen of *Quercus virginiana*, *Aquilegia* sp., *Ranunculus macranthus*, *Prosopis glandulosa*, *Tradescantia paludosa*, *Parkinsonia aculeata*, *Hippeastrum belladonna*, and *Ambrosia psilostachya*, have been examined in the electron microscope. In addition, developmental stages of *Parkinsonia aculeata* and germinated pollen of *P. aculeata* and *Ranunculus macranthus* have been observed.

The fixative for electron microscopy was predominantly $KMnO_4$, though $Sr(MnO_4)_2$, $NaMnO_4$, and OsO_4 have also been used. Epoxy resins have been used as the embedding matrix and observations following diamond knife sectioning were made in Radio Corporation of America electron microscope models *EMU-3-D* and *EMU-3-F*.

In every species examined, the generative nucleus has had an associated cytoplasm separated from the vegetative cytoplasm by paired plasma membranes (Fig. 1). In *Ambrosia*, which is tri-nucleate at pollen maturity, sperm cells exist with obvious plasma membranes, and sperms in pollen tubes of *R. macranthus* also exist as cells. Between the paired plasma membranes is an area of variable width (in fixed grains) which is devoid of hyaloplasm but which does have a number of minute vesicles. No complete intercellular connexions have been observed and the mobility and highly plastic nature of the generative cell argues against the presence of such connexions.

No evidence of a cell wall has been observed, though cell walls are obvious in electron micrographs of multicellular mature cycad pollen. The pleomorphic nature of the generative cell is best observed during pollen tube growth, but it can also be seen in fixed specimens when the generative cell had progressed into the pollen tube prior to fixation, or when 'frozen' in the process of flowing out a ruptured pollen grain.

In mature grains of every species studied, the cytoplasm of the generative cell differs markedly from that of the vegetative cell (in *Parkinsonia aculeata*, the differentiation of the two cytoplasms out of a uniform common cytoplasm begins immediately after the establishment of the two cells following the first microspore mitosis). Every cell organelle and the hyaloplasm, or ground substance, is found to differ in fixed specimens. Mitochondria are fewer in number per unit area, have smaller dimensions in profile and have fewer cristæ ; distribution of mitochondria is generally random. Plastids were identified in a majority of the species and are most clearly seen in *Hippeastrum belladonna*. In general, generative cell plastids are difficult to identify because of their smaller dimensions, paucity of internal membranes, and because they do not contain stored starch; in *Ranunculus macranthus*, and others in which amyloplasts occur in the vegetative cell, starch is definitely absent from mature generative cells. Generative cell plastids appear to be rare and the average section does not contain a plastid profile.

Golgi structures are a normal element of the generative cell ; but they, too, are fewer in number, have fewer cisternæ, and do not have nearly the number of associated vesicles that the vegetative cell Golgi structures do. Free vesicles, abundant in vegetative cell cytoplasm, are infrequent in the generative cell. During pollen tube growth, Golgi structures in the vegetative cell produce numerous large vesicles while the Golgi structures in the generative cell remain inactive. The large vesicles produced by the Golgi of the vegetative cell are associated with pollen tube wall synthesis[6].

The endoplasmic reticulum in the generative cell is significantly reduced in amount. Especially noteworthy is the reduced membrane spacing in generative cells, while the endoplasmic reticulum of vegetative cells has a wide membrane spacing. Differences in hyaloplasm densities between the two pollen cells occur in each species, but the appearance is not consistent, being either of greater or lesser density in the generative cell. Inclusions often identified in the literature as lipid or protein bodies are common in vegetative cells ; they have only been observed in generative cells of *Hippeastrum*. Not uncommonly, the vegetative nucleus is polymorphic and appears to be degenerative. Venema and Koopmans[3], among others, have reported degeneration of the vegetative nuclei of some species prior to or during pollen germination.

These observations of cytoplasmic fine structure are consistent with the limited results of Bopp-Hassenkamp and in general detail with earlier optical studies. The taxonomic distribution of the species studied so far permits one to state a tentative generalization, namely, that the generative and sperm cells have a cytoplasm distinct from that of pollen vegetative cells and that the appearance of generative cell cytoplasm is one of reduced metabolic potential. Fischberg and Blackler[7] have suggested that, in animal development, germ plasm serves to protect germ nuclei from developmental modifications. It is possible that generative and sperm cell cytoplasm functions in like manner. Safijovska's observation on generative cell longevity and the fact that during pollen germination generative cell cytoplasm does not show the increased activity that vegetative cell cytoplasm exhibits suggests a decreased environmental sensitivity.

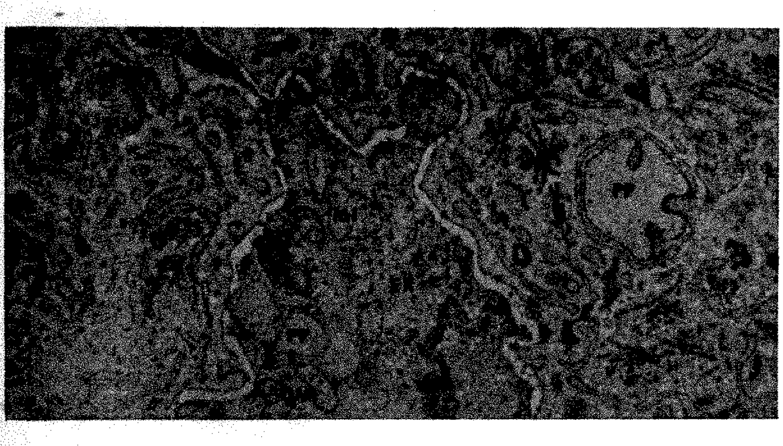

Fig. 1. Generative cell (centre of figure) in mature pollen grain of *Hippeastrum belladonna*. *MI*, mitochondrion; *ER*, endoplasmic reticulum; *GA*, Golgi apparatus; *PP*, proplastid; *CM*, cell membrane; *I*, inclusion. (Permanganate fixed. × *c*. 10,200)

Effects of 2-Chloroethyltrimethylammonium Chloride and 2,4-Dichlorobenzyltributyl Phosphonium Chloride on Growth and Transpiration of Slash Pine

The growth of many plants, including several tree species, can be retarded by CCC (2-chloroethyltrimethylammonium chloride) and 'Phosfon-D' (2,4-dichlorobenzyltributyl phosphonium chloride)[1–5]. In addition, CCC applied as a soil drench has led to increased flowering in some plants[6–8].

A small lath-house experiment, designed to test the effects of these compounds on 1-year-old potted slash pine (*Pinus elliottii* var. *elliottii*) seedlings, was installed at Olustee, Florida, in February 1962. Treatments consisted of: (1) CCC soil drench at rates of 0, 5, 10, 20 and 40 g/ft.^{3} potting soil; (2) 'Phosfon-D' soil drench at rates of 0, 0·4, 0·8, 1·6, and 3·2 g of technical material per cubic foot; (3) CCC foliar spray at concentrations of 0, 2,000, 4,000, 8,000 and 16,000 p.p.m.; and (4) CCC foliar spray at the above concentrations plus 0·15 per cent wetting agent (Fasco 'Spreadhesit'). Soil drench applications were made in February, April, May, and July 1962. Foliar sprays were applied with a hand-operated 'flit gun' twice weekly, from February to September 1962. The experiment was set up in a randomized block design, replicated six times. Height measurements to the nearest 0·1 cm were taken at 2-week intervals throughout the growing season.

'Phosfon-D' concentrations were apparently too low to affect height growth of the seedlings, although it is possible that slash pine does not respond to this compound. Since 'Phosfon-D' is reported to be highly persistent in the soil, concentrations of 1·2, 2·4, 4·8 and 9·6 g per cubic foot should have existed in the soil by July. Cathey[2] has observed that approximately 25 times as much CCC as 'Phosfon-D' is required to retard the height growth of chrysanthemums. Nevertheless, complete lack of toxicity or other symptoms at the highest level of 'Phosfon-D' indicates that the dosages were too low.

CCC applied as a foliar spray, either with or without a wetting agent, significantly depressed seedling height growth. However, extensive damage to foliage (needles stunted and chlorotic) and developing shoots resulted at the two highest concentrations (8,000 and 16,000 p.p.m.), to the extent that this form of application is considered impractical.

The treatment showing most promise was the application of CCC as a soil drench (Table 1). Growth of trees receiving 40 g/CCC/ft.^{3} soil became significantly less than check tree growth by the 10th week of treatment, levelling off at approximately 35 per cent of check tree growth from the 20th week on. Treatment effects were significant at the 0·005 level, with seedling height growth decreasing linearly with the logarithm of concentration. There was no apparent damage to the foliage.

Table 1. Effect of CCC Soil Drench on Total Seedling Height Growth

Concentration (g/ft.^{3} soil)	Average height growth (cm)	Percentage of check tree growth
0	28·8	100·0
5	25·9	89·8
10	29·0	100·7
20	18·6	64·6
40	18·6	64·6

Table 2. Effects of CCC Soil Drench on Seedling Transpiration (72-h Weight Loss in g)

Concentration (g/ft.^{3} soil)	Average 72-h weight-loss (g)	Percentage of check tree loss
0	409·2	100·0
5	235·8	57·6
10	177·5	43·4
20	90·8	22·2
40	85·8	21·0

It was noted early in the course of the experiment that soil in pots receiving CCC as a soil drench remained moist when other pots were relatively dry. On June 4, 1962, the potting soil was saturated with tapwater and allowed to drain overnight. On June 5, all pots were enclosed in polyethylene bags and weighed. Subsequent weighings were made on June 6, 7 and 8. Analysis of the data (total 72-h weight-loss) revealed a reduction, significant at the 0·005 level, in transpiration of seedlings receiving CCC either as a soil drench or foliar spray (Table 2). Response, as in the case of height growth, was linearly related to the logarithm of concentration.

As in the case of height growth, reduced transpiration of seedlings receiving CCC as a crown spray was difficult to assess because of foliar damage. The response to soil application is more clear-cut, since foliar damage is entirely absent. Height of the tree was considered as a possible contributing factor, but only a slight correlation ($r = -0{\cdot}055$) was found between total height of the check seedlings at the time of initial weighing and 72-h weight-loss.

After soil application of CCC at the two highest levels (20 and 40 g/ft.^{3} soil), needles on treated trees were noticeably shorter than check tree needles. Fascicles from three different vertical positions on the current season's leader growth were clipped off and measured. Comparison of the needle-lengths of check trees with those from trees treated with the two high-level soil applications of CCC showed a significant difference ($t = 5{\cdot}132$, $P < 0{\cdot}001$). However, that needle length *per se* cannot account for the observed reduction in transpiration of treated seedlings is evidenced by the fact that the correlation between average needle length of check trees and 72-h weight-loss is not significant ($r = 0{\cdot}146$). One can only conclude that: (1) the observed reduction in transpiration is not due solely to reduced length of needle or size of tree; (2) the reduction is not due to blocking of water movement into the tree stem, since wilting does not occur. Possible factors are a reduction in stomatal opening due to the treatment, either directly or via reduced photosynthetic rate, reduced water utilization in the treated trees, and retarded root development.

I thank Dr. H. M. Cathey of the Agricultural Research Service, U.S. Department of Agriculture, Dr. R. E. Deems of American Cyanamid Company, and Dr. Staley L. Felton of Virginia-Carolina Chemical Corporation for their advice and assistance. Chemicals used in this experiment were kindly furnished by American Cyanamid Company (CCC) and Virginia-Carolina Chemical Corporation ('Phosfon-D').

Diffusion Chambers for the Collection of Helminth Antigens

In comparing the immunological responsiveness, in relation to a particular nematode, of old-established hosts on one hand and newly established hosts on the other[1], it was necessary to obtain an antigen which could be presumed to have been immunologically active over evolutionary time, that is, a natural product of normal infection. It was therefore essential to collect the excretions and secretions of worms living under conditions resembling as nearly as possible the natural environment, in this instance the liver and abdominal cavity of rats.

Recourse was made to diffusion chambers for this purpose, the principle involved being to transfer third-stage larvæ from the original host to the diffusion chamber, which was then inserted into the abdominal cavity of a recipient host. Larvæ removed from the donor 5 weeks–6 months after experimental infection were observed to remain alive in the capsules for at least a week.

The technique involved removal of 10–15 worms from the abdominal cavity under aseptic conditions and their insertion into the capsule, which was then inserted into the peritoneal cavity, which had been opened by midline incision. The recipient rats were given intramuscular benethamine penicillin (10,000 I.U.) and 0·03 g streptomycin sulphate after the insertion of the capsule, which was left *in situ* for 7–10 days, then removed and opened. The contents of the capsule were washed out with about 1 c.c. of sterile distilled water and, after separation of the worms, the fluid was centrifuged and used as antigen.

The diffusion chambers were made from three types of membrane, each with a different pore size. The first type (*DC*1) was made from size 8/32 Visking dialysis tubing (Visking Co., Chicago). About 18 cm of the tubing was cut and sterilized by placing in 1 per cent 'Cetavlon–Hibitane' solution (Imperial Chemical Industries, Ltd.) for 48 h before use. One end was tied off and the worms were inserted into the open end with about 3 c.c. of sterile physiological saline. The other end was then tied off and both ends carefully trimmed, so as to leave as little rough edge as possible.

The other capsules (*DC*2 and *DC*3) were made from membranes prepared by 'Membranfilter', Göttingen, Germany. Two 50-mm membranes were used to form each capsule. The two sizes used were 'Membranfilter Gruppe 5' (*DC*2) and 'Ultrafein Filter' (*DC*3). These capsules were prepared by means of a carpenter's 'G' clamp and two stainless cylindrical moulds 29 mm diam. and 19 mm thick (Fig. 1). On one of the flat sides of each mould was a depression 25 mm diam. and 9 mm depth. One 50-mm circular sheet of membrane was placed over the mould with the depression uppermost. The worms in sterile physiological saline were placed on the membrane, which was pushed into the depression on the mould. Another membrane was placed over the worms and the second mould, with depression downwards, was placed over this membrane. The two moulds were placed in the clamp and tightly opposed. The opposing membrane edges, protruding outside the moulds, were then joined with acetone, trimmed, and after a few seconds for drying, they were removed from between the moulds by loosening the clamp. After washing in sterile distilled water, the chamber was now ready for insertion.

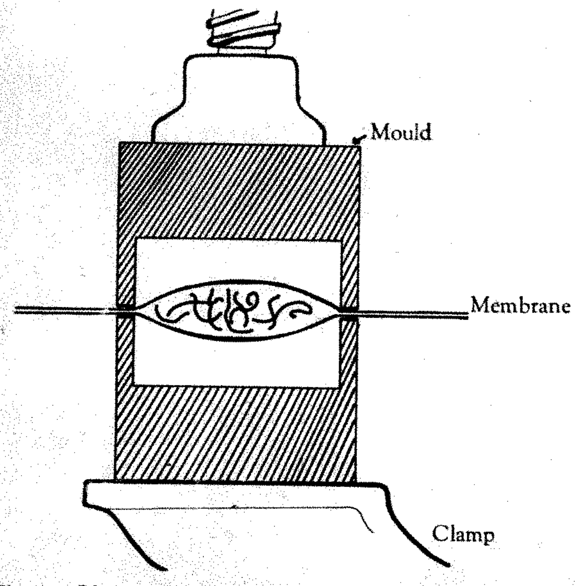

Fig. 1. Diagram showing preparation of capsules *DC*2 and *DC*3

The fluid obtained from the different chambers (*DC*1, *DC*2 and *DC*3) was tested by the complement fixation reaction and by gel-diffusion against sera from infected rabbits and rats, as well as against normal serum, and against the serum of rats after harbouring the capsules. The fluid from each disk gave positive complement fixation, and strong Ouchterlony gel diffusion lines with infected rabbit sera. With infected rat sera no complement fixation occurred, the serum showing anticomplementary activities, but gel-diffusion lines were strongly developed. No reaction occurred with normal rabbit and rat sera, or with the sera of rats harbouring the capsules.

The contents of the three types of capsule varied in reactivity with infected rabbit serum, that obtained from capsule *DC*1 showing a higher complement fixation titre than that from capsules *DC*2 and *DC*3.

ENTOMOLOGY

Histology and Possible Functions of Neurosecretory Cells in the Ventral Ganglia of *Schistocerca gregaria* Forsk.

Although neurosecretory cells were shown to exist in the ventral ganglia of insects as early as 1940[1], students of neurosecretion in the group have concentrated on the brain and rather neglected the ventral nerve-cord. This neglect prompted me in 1959 to begin studying the ventral ganglia of *Schistocerca gregaria* (Orthoptera : Acrididae) in some detail, and though, since starting the work, three papers on the histology of the ventral ganglia of other insects have appeared[2–4], a summary of the rather different conditions in *Schistocerca* seems desirable.

All four main types of neurosecretory cells found in insects and often denoted, for example by Highnam[5], as *A*, *B*, *C* and *D* cells have been shown to occur in the ventral ganglia of *S. gregaria* (Fig. 1). The *B* cells are not phloxinophil, however, and therefore not identical with the *B* cells of the pars intercerebralis of the brain[5]. The *B*, *C* and *D* cells occur in all the ventral ganglia, but their number and position vary from one insect to another. The *A* cells are constant in number and location, and occur in all ventral ganglia except the last abdominal one. Neurosecretory cells are absent from the frontal, hypocerebral and ingluvial ganglia of the stomatogastric nervous system.

The *A* cells may be divided into three sub-types : *A*1, *A*2 and *A*3 cells. The *A*1 cells are peculiar in undergoing great changes in volume during sexual maturation of the female, while the *A*2 cells are unique in that their secretory material appears in Azan-stained sections as large droplets which are coloured brilliant red with azocarmine. Both are thus easily distinguished from the *A*3 cells which show neither of these characteristics. *A*1 cells occur in all the ventral ganglia except the last ; there are 2 in each ganglion except for the third (compound) thoracic ganglion, which has 6 arranged in three pairs, apparently derived from the three primitive abdominal ganglia which have fused with the metathoracic ganglion to form the compound structure. *A*2 cells are found in the third thoracic and first four abdominal ganglia ; there are 4 cells in each abdominal ganglion and this pattern is repeated three times in the posterior end of the third thoracic ganglion. The *A*3 cells, of which there are 2, lie close together one on each side of the mid-ventral line of the sub-œsophageal ganglion. The *B* cells fall into two sub-types : *B*2 cells stain with aniline blue in Azan preparations, while *B*1 cells do not. The *A* cells undergo secretory changes correlated with maturation and oviposition in the female ; no such changes have been demonstrated for the *B*, *C* and *D* cells. On histological grounds, the *C* and *D* cells appear to be different stages in the secretory cycle of a single functional type of cell.

Axonal transport of neurosecretory material was studied by ligaturing experiments and by nerve section. Neurosecretory material passes backwards and forwards along the double ventral nerve cord, outwards along at least some of the nerves originating from the ganglia, as well as along the axonal tracts from the neurosecretory cells of the pars intercerebralis to the corpora cardiaca. No such transport has been demonstrated along the circum-œsophageal connectives. Neurosecretory cells whose axons have been cut contain after five days less neurosecretory material than those with intact axons. Evidence from ligation of the axonal routes of neurosecretory cells suggests that, in the ventral ganglia, cells packed with neurosecretory material may be actively secreting and those with little such material are quiescent. The same conclusion on secretory dynamics seems to be supported by preliminary autoradiographic investigations on the *A*3 cells of the sub-œsophageal ganglion, using ^{35}S-DL-cystine.

Students of reproductive physiology have in the past correlated the process of egg maturation with the neurosecretory material derived from the *A* cells of the brain[6,7] and the hormones secreted by the corpora allata[8,9]. In the work recorded here it was found that extirpation of the last abdominal ganglion in newly emerged *Schistocerca* prevents egg development ; that implantation of the ganglion into a locust the ganglion of which had previously been extirpated results in egg development if the implantation is done after about 2–3 weeks following the extirpation, and if the donor was about the same age as the recipient ; and that the complete nervous isolation of the ganglion by section of the ventral connectives and the peripheral nerves did not prevent egg maturation. The desert locust normally matures after about 3 or 4 weeks of adult life, and the first egg pod is not normally laid before the age of 4 weeks[10]. But when either the last abdominal ganglion or the corpus cardiacum of a mature female is implanted into a newly emerged female, the latter begins to copulate after about a week and lays the first egg pod on the 10th day. Similar results are obtained when both the ganglion and the gland from a mature female are implanted together into a newly emerged female ; that is, maturation is not accelerated further by a double implant. Controls consisting of locusts with cuticular incisions matured in 3 or 4 weeks, as did normal locusts. These findings support the view that a hormonal factor, in the provision of which the last abdominal ganglion is concerned, helps to control egg maturation, though the source of such a hormone does not seem to lie in any of the neurosecretory cells found in this last ganglion by the above histological study.

Examination of the neurosecretory system of locusts which had been flown for periods of 4–58 h on a simple motorized flight roundabout showed that there had been a heavy discharge of neurosecretory material from the third thoracic and all the abdominal ganglia, and no discharge in the sub-œsophageal and first two thoracic ganglia. This discharge is therefore not likely to be due to 'stress'[11] since under such conditions one would imagine that the neurosecretory cells of the anterior ganglia would also discharge their contents. Furthermore, the distribution of the *A*2 cells in the posterior ganglia would seem to suggest that it is these cells which discharge during flight.

A series of simple dehydration experiments tend to suggest that the discharge of neurosecretory material from the *A*2 cells of the ventral ganglia is also correlated with water loss. Forty newly emerged females were separated into four groups of 10 each. One group was reared on bran alone, a second without food or water (that is, starved), a third on water alone, and a fourth on both food and water. Examination of the neurosecretory system after 14 days showed that there was a heavy discharge of material from the third thoracic and abdom-

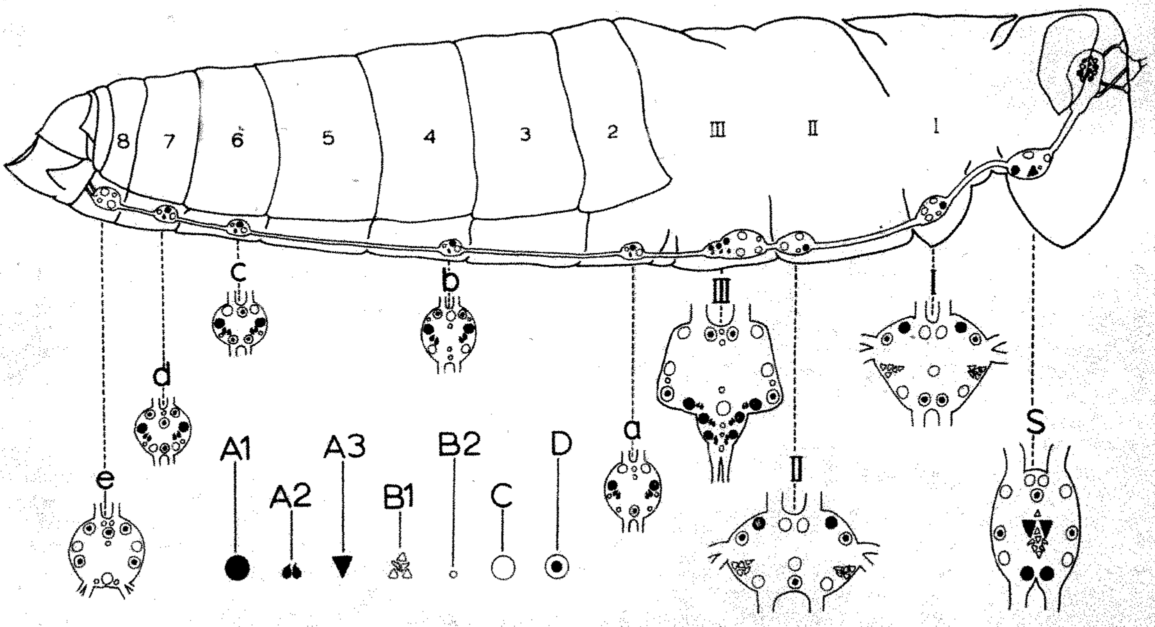

Fig. 1. Distribution of neurosecretory cells in the ventral ganglia of *Schistocerca gregaria* Forsk. *S*, sub-œsophageal ganglion ; I, II, III, thoracic ganglia ; *a* – *e*, abdominal ganglia

inal ganglia of locusts reared without water, similar to the results obtained in the flight experiments, whereas no discharge occurred in locusts with access to water. Neurosecretory discharge under these conditions has no parallel in the literature, and it is tentatively suggested that the *A*2 neurosecretory cells of the abdominal ganglia secrete an antidiuretic hormone[12] which is released under conditions in which water conservation might be necessary.

I thank Prof. O. W. Richards for providing me with research facilities at the College Field Station, Sunninghill, Berkshire, Mr. R. G. Davies for advice, Sir Boris Uvarov, and the Director and Staff of the Anti-Locust Research Centre, London, for supplying locusts and for many helpful discussions, and Dr. D. B. Carlisle for translating Panov's paper.

Transmission by Filariasis in the Philippine Islands by *Anopheles minimus flavirostris* Ludlow

The highest endemicity of filariasis in the Philippine Islands occurs in the extensive abaca-growing areas of the Bicol Peninsula, Samar, Leyte and Mindanao[1]. Here the principal vector is the plant-cavity breeding *Aedes* (*Finlaya*) *poicilius* (Theobald), which is able to exist in dense populations because the abundant rainfall keeps the leaf axils of the abaca trees filled with water[1]. In our survey of 1954–55 (ref. 2), we showed a general correlation between the presence of abaca and filarial endemicity, but there were two notable exceptions. One of these was in the northern mountain province of Luzon. Through the co-operation of the Malaria Eradication Unit stationed at Tabuk, we received a sample of night blood films which showed a 29 per cent microfilaræmia-rate.

At that time we were unable to inspect the area from which the smears were reported to have been taken. The purpose of the work recorded here was to confirm the presence of filariasis among the indigenous, non-immigrant population, and to ascertain the environmental factors which would permit the disease to exist in this improbable area.

Our study area includes the barrio of Calaccad, some 15 miles south of Tabuk; from which it is accessible only by foot trails. The Kalinga tribespeople live in isolated, single family units, or in groups of 2 to about 6 families. These single houses, or groups of houses, are half a mile or more apart. Most of the dwellings are situated near small streams, which are heavily wooded with bamboo and deciduous trees. In Calaccad the forests are being depleted rapidly by dry season burning for rice cultivation. A few large trees remain in the relict forest patches.

Our night blood film survey during the past dry season showed an overall microfilaræmia-rate of 10·7 per cent in this diffuse population at Calaccad. There was a tendency for positive cases to be grouped, so that in several of the tiny settlements or 'sitios', of from 8 or 9 to 25 people examined, we obtained infection-rates up to 32 per cent.

The houses are built several feet above the ground on posts; the walls are made of split bamboo or sawali, and the roofs are thatched with cogon-grass. Almost all have been sprayed with DDT for the past 10 years. We have been unable to capture more than an occasional mosquito inside the houses. In order to obtain large numbers for dissection, we have made use of a large screened trap baited with a carabao. This trap was set up in the vicinity of a house in which 4 of the 7 inhabitants are infected with periodic *Wuchereria bancrofti*. Although most mosquitoes attracted to a carabao-baited trap are zoophilic, it seemed to us reasonable to assume that some of the insects which had previously fed on one of the human cases would be seeking their later meals from a carabao. It must also be understood that a large proportion of the mosquitoes caught in such a trap would be taking blood for the first time. Therefore, one could not anticipate a high infection-rate. The collections were made early in the morning, and the dissections were completed during the following day or two.

Apart from *Aedes vexans*, the only persistent man-biting species which also occurred regularly in the trap was *Anopheles minimus flavirostris*. Of 207 *flavirostris* examined so far, 4 have been found infected with filarial worms. In one there was a single second-stage larva in the thoracic muscles. Two of the specimens each contained 3 mature third-stage infective larvæ. In one the larvæ were in the thorax, and in the other they were in the head. In the fourth specimen, there were 2 sausage-stage larvæ in the thorax and a highly active motile infective larva in the proboscis. All the mature larvæ agreed in morphology with published descriptions of *Wuchereria bancrofti*. Also they were identical with *W. bancrofti* larvæ we have observed in mosquitoes in our previous investigations. We are offering these findings as evidence that in this area, where small foothill streams furnish an ideal environment for *A. minimus flavirostris*, this species is a natural vector of *Wuchereria bancrofti*.

This investigation was conducted under the auspices of the Commission on Parasitic Diseases of the Armed Forces Epidemiological Board, and was supported in part by the Surgeon General, Department of the U.S. Army.

CYTOLOGY

A Cytochemical Method for Electron Microscopy

Methods for specifically staining tissue constituents for electron microscopy are at present inadequate for the identification of important molecular species in the cell. The range of application of the electron microscope in biology is thereby severely limited.

It occurred to us that more specific stains might be prepared by complexing heavy metal atoms with enzymes of high substrate specificity. It was hypothesized that, even though the activity of the enzyme might be impaired by the presence of the metal atoms, substrate-bonding specificity might be retained sufficiently to bring about localization of heavy atoms at the substrate locus in the cell.

This communication describes preliminary experiments which tend to bear out this hypothesis.

The substrate and enzyme selected for the first experiments were DNA and DNase. The DNase was treated by a procedure believed likely to result in the formation of a mercuric–DNase complex. A solution of the enzyme (Sigma Biochemical Co., Grade *DN-C*) at a concentration of 1 mg/ml. in deionized water was mixed with nine volumes of a 0·005 M solution of mercuric chloride in 0·05 M pH 7·4 glycylglycine buffer at 5° C. The mixture was dialysed against cold glycylglycine buffer for three days to remove the non-enzyme-bound mercuric ion. The activity of the treated enzyme after dialysis was determined to be a small fraction of the original activity.

Although it seemed unlikely that after fixation, dehydration and embedding, a cellular substrate such as DNA would be in sufficiently native condition to interact with enzyme, it was decided to make a staining trial under these conditions because of the technical advantages to be realized in the event of it working. The dialysed mercuric enzyme solution was therefore used directly as a stain on thin sections of tissues embedded in 'Araldite' resin. The sections, adherent to 500-mesh copper specimen grids, were immersed in the mercuric-enzyme solution at room temperature for 5 min, rinsed vigorously with distilled water, and examined in the electron microscope.

Various cells of neural origin were used as test specimens. These included : human meningioma cells (in tissue culture for 37 days prior to fixation) ; re-aggregates of 7-day chick neural retinal cells; neurones from the earthworm nerve cord; and neurones and associated glial cells from hamster spinal sympathetic ganglia.

The test specimens had been fixed by several different procedures. Isotonic 0·6 per cent permanganate fixation at physiological pH had been used for most tissues ; some permanganate-fixed tissues had been intensified after sectioning with a potassium hydroxide-complexed potassium plumbate solution (our method, not yet published) ; the embryonal neural retinal re-aggregates had been fixed in an isotonic buffered osmic acid solution. All specimens had been dehydrated in graded acetone solutions and embedded by transfer from 100 per cent acetone into the final embedding mixture at 55° C. No influence of the method of tissue preparation was apparent in results obtained with the enzymatic staining procedure.

All staining trials were positive in that, after immersion in the mercuric–DNase solution, the nuclei of the cells, and only the nuclei, showed areas of increased electron density which were unlike any figures seen in sections not thus treated. The shapes of the stained regions of the nuclei were in all cases more or less fibrillar. In certain kinds of cells including embryonal neurones, Schwann cells, and meningioma cells, the darkened regions were relatively condensed and had high contrast. In neurones of the sympathetic ganglia, the contrast of the stained regions was relatively low, but the resolution of strands was comparatively good. Suggestions of a banded structure were not infrequently present in the fibrils.

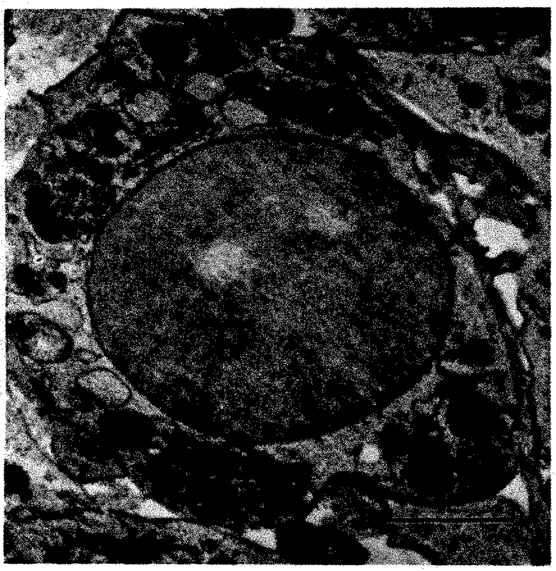

Fig. 1. Electron photomicrograph of cell from tissue culture of human meningioma. Permanganate fixed, 'Araldite' embedded. Scale = 2μ

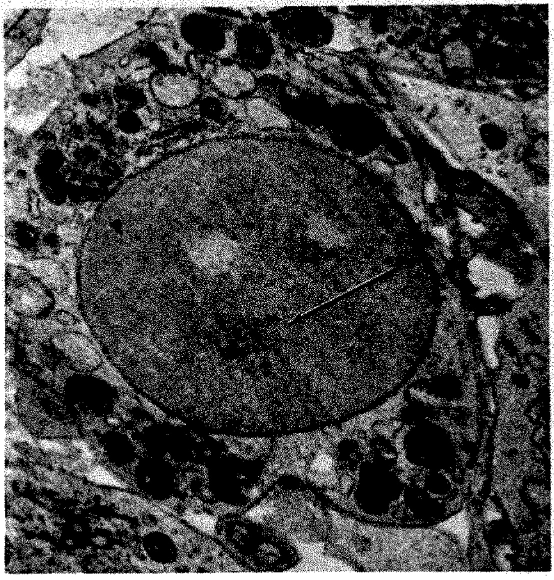

Fig. 2. Same area as in Fig. 1 after exposure of section to mercuric–DNAase solution

To demonstrate the change which results from immersion in the mercuric–DNase solution, a selected nucleus from a human meningioma culture was photographed before and after exposure to the staining solution. Fig. 1 shows this nucleus prior to staining. Fig. 2 is the post-staining picture. The arrow in Fig. 2 indicates the region of density increase. Note that the mercuric-DNase stain took effect on this specimen despite a lengthy exposure to the microscope beam prior to staining. The two light regions in this nucleus are areas of reduced electron density surrounding nucleoli not seen in this section. The dense masses in the cytoplasm, regularly seen in electron micrographs of this tumour culture, are believed to be an abnormal lipoidal product.

In other micrographs, the stranded material the density of which was increased by exposure to the complex was seen to terminate on the nuclear membrane in frequent instances. When a number of such strands were present parallel to the plane of sectioning, the nucleus had the unexpected appearance of a giant mitochondrion, the strands resembling, though not in detail, the arrangement of mitochondrial cristæ.

It is likely that the modified enzyme did not penetrate the epoxide-embedding material, but rather bound only to DNA at or near the surface of the section. A better result might be expected if the technique were used in conjunction with a more permeable or wettable embedding medium, or from the use of enzymes of smaller molecular dimensions than DNase. The dielectric properties of the embedding material might also be found to affect the bonding between the enzyme–metal complex and the fixed substrate. Surface charge patterns induced in the resin by the presence of the substrate might be effective in attracting the enzyme to the surface of the section. Experiments with various embedding materials are in progress.

Should our present work of testing the generality of this method show it to be applicable to other enzyme–substrate combinations, a widely useful tool will be available for electron microscope cytochemistry. Our present work includes efforts at extension of this technique to include localization of intracellular RNA and neurotransmitter substances, as well as application of metal-complexed DNase to metaphase chromosomes. The investigations also include the use of metal-complexed enzymes as vital stains prior to fixation and thin sectioning of tissues. Further work is in progress to characterize the presumed mercuric–DNase complex in detail.

In view of the possibility that enzyme-substrate interactions can occur between an embedded substrate and an aqueous enzyme solution, it would seem reasonable to attempt the complementary experiment of attempting to locate intracellular enzyme by applying a solution of metal-complexed substrate to tissue sections.

GENETICS

Karyotype of *Theligonum cynocrambe* L.

The family Theligonaceae has one genus *Theligonum* L. (= *Cynocrambe* Tourn.) in which four species have been reported: *T. japonicum* Okubo and Makino, *T. macranthum* Franch., *T. cynocrambe* L. and *Cynocrambe formosana* Ohwi. Two of these species have been cytologically examined previously by other workers. Schneider[1] reported that *T. cynocrambe*, a Mediterranean species and an annual, had a somatic chromosome number of $2n = 20$ and a meiotic count of $n = 10$. In contrast to this, Sugiura[2] found that *T. japonicum*, a perennial from Japan, had a meiotic count of $n = 11$. He did not report on the somatic chromosomes of this species.

In 1961 seed of *T. cynocrambe* was collected from the Piana degli Albanesi district of Sicily about ten miles south of Palermo by Dr. C. D. Cook. Plants were grown from this seed, the chromosome complement was examined, and a voucher specimen deposited at the British Museum Herbarium.

Root tips were pre-treated for 2 h in 0·05 per cent colchicine solution and fixed in 3:1 alcohol/acetic. They were then hydrolysed for 10 min in hydrochloric acid at 60° C, stained for 1 h in Feulgen, mounted in aceto-orcein to counterstain, teased and squashed. The chromosome number of $2n = 20$ was observed in all cells. This agrees with the count made by Schneider in 1914.

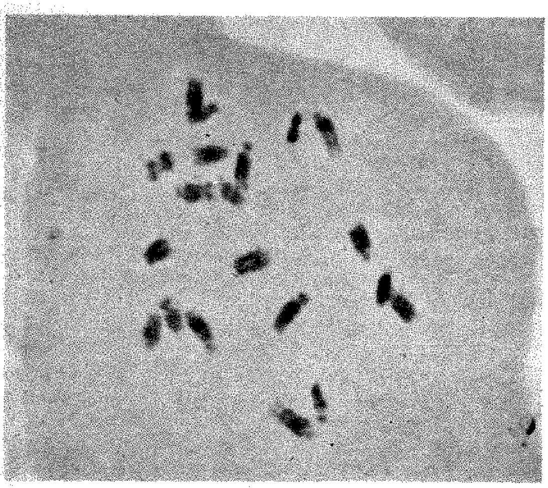

Fig. 1. Somatic metaphase plate from a root tip of *Theligonum cynocrambe*, $2n = 20$ (× 2,000)

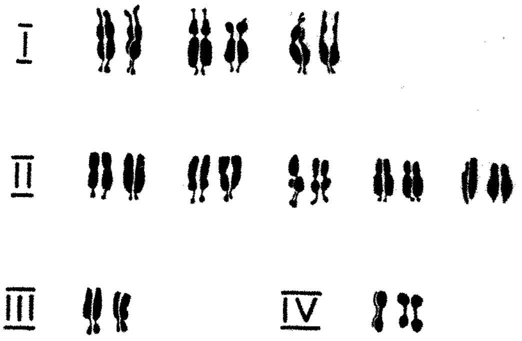

Fig. 2. Karyotype analysis of *Theligonum cynocrambe* (× 3,000)

The degree of chromosome contraction, due to the colchicine pre-treatment, varied slightly from cell to cell, but this method allowed karyotype analysis to be carried out with accuracy. Four groups of chromosomes can be distinguished (Figs. 1 and 2). (I) Three pairs of large acrocentric chromosomes ranging from 2·6 to 2·8μ in length; (II) five pairs of small acrocentric chromosomes ranging from 1·7 to 2·0μ in length; (III) one pair of acrocentric chromosomes with more prominent short arms, the short arm 0·6μ and the long arm ranging from 1·3 to 1·4μ in length; (IV) one pair of metacentric chromosomes, 1·7μ in length.

Chromosome morphology was seen best in those cells where the pre-treatment had produced the least contraction of the chromosomes but had clarified the position of the centromere and secondary constriction regions. The members of group I have two secondary constrictions and in those of group II there is evidence of a single secondary constriction. Drawings from root-tip cells by Schneider[1] do not show any of these details.

Similar karyotype analysis of the other species of this genus will be of interest in view of the different basic chromosome numbers reported. These will be done as material becomes available.

A Red Eye Colour Mutation in *Culex pipiens* after X-irradiation

Four 1–2-day-old males of *Culex pipiens* were irradiated with a dose of 4,000 r. The mutant 'red eye' (*r*) was isolated from F_3 cultures of two of the irradiated males (♂ II and ♂ IV). From male II, there were three red-eyed females which arose out of a single F_2 brother–sister mating; from male IV, 80 red-eyed females and one red-eyed male from 14 F_2 brother–sister matings. According to the experimental procedure, this means that at least one sperm from male II and at least fourteen sperms from male IV carried the mutation *r*. Thus, the same mutation was recovered in parallel from two irradiated males. The clustered appearance of the mutation in male IV was presumably caused by the occurrence of the mutation in a spermatogonial cell.

While the normal eyes of the larvæ, pupæ, and adults appear pigmented dark brown to black, the mutation *r* causes a red eye colour in place of black. In the late embryo of the normal animals, one recognizes two brownish red eye spots, which in the larvæ darken to brown or black. The eyes of the advanced larvæ, pupæ, and adults appear completely black. The embryonic eye spots of the mutants, on the other hand, are faded orange in colour. The orange hue becomes more intense and turns to red in the fourth larval instar. The eyes of young adults are light red. In several days old animals, the red colour begins to darken; in older animals the eyes are deep dark red. The nature of the red colour substance has not been clarified as yet.

Crossings of the various *r*-isolations with one another gave red-eyed F_1 progeny in every case. Accordingly, the mutation is the same in all red-eyed animals. *r* is inherited as a recessive, shows full penetrance and no variability of expression.

Table 1. DATA ON INHERITANCE OF THE MUTATION *r*: NORMAL ♀♀ CROSSED WITH RED-EYED ♂♂

Generation	♀♀ Normal	♀♀ Red-eye	♂♂ Normal	♂♂ Red-eye
F_1	68	—	98	—
F_2	378	—	199	165

Among the red-eyed animals there were 83 females and only one male. This indicates that the factor for red eyes is sex-linked. Sex in *Culex* is determined by a single gene[1]. The male is heterogametic and the female homogametic, with dominance of the male factor *M* over *m*. Crosses with normal-eyed animals confirm the linkage of the mutation to sex (Table 1). In the F_2 the red eye colour reappeared in the males only. In this experiment, the linkage with sex was complete; in other cases, however, as a result of crossing over between the sex factor and the factor *r*, a small percentage of red-eyed animals appeared among the females. The only male in the radiation experiment must have originated also through crossing over.

A spontaneous white-eyed mutation is also available in this laboratory. Since white is also sex-linked, it was suggested that white and red were multiple alleles. However, a fully normal F_1 progeny was obtained from a cross with white-eyed females and red-eyed males. Thus, the two factors are not multiple alleles.

Autoradiographic Studies of *X*-chromosome Duplication in an *XO*/*X*-isochromosome *X* Mosaic Human Female

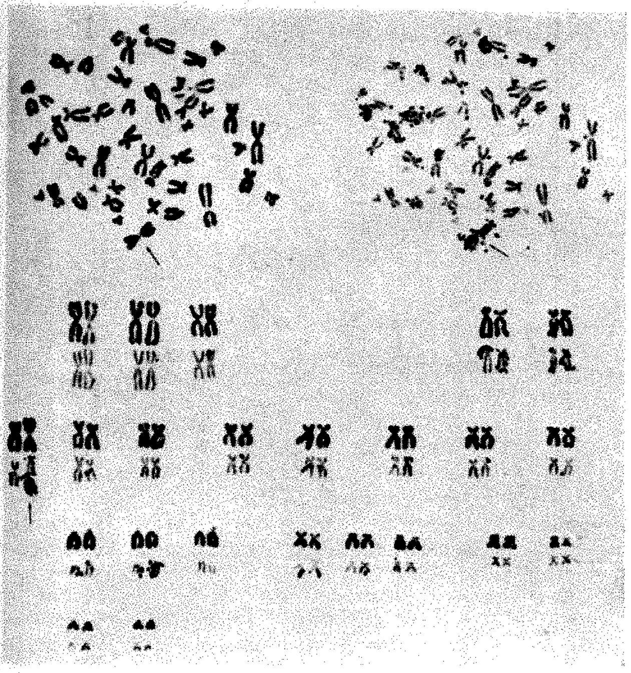
ACCORDING to Lyon's hypothesis[1,2], one of the two *X*-chromosomes in each *XX* cell of the normal human female and perhaps in all mammalian females is genetically inactivated at a certain stage of embryogenesis. This inactive *X* chromosome becomes condensed or heteropycnotic and forms the sex chromatin. Inactivation is presumed to occur at random. The heteropycnotic *X* can thus be either maternal or paternal in origin. Ohno and Cattanach[3] have recently provided direct cytological evidence of this in the mouse. In the skin of animals with a variegated phenotype due to a translocation of the wild-type allele of a coat colour gene to the *X* chromosome (X^t), the wild-type patches of skin were populated by cells containing a condensed inactive chromosome (presumably the normal *X*). Mutant-type patches from the same animal contained cells in which a visibly larger chromosome, presumably the X^t, was heteropycnotic.

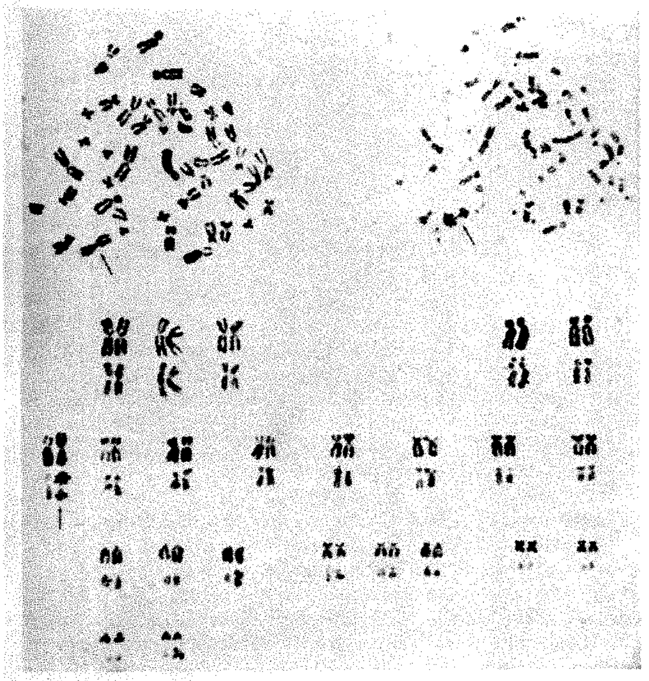
Random inactivation of maternally or paternally derived *X* chromosomes may not always occur. In human females with one normal *X* and one structurally abnormal *X* chromosome, the sex chromatin is consistently abnormal in size. It conforms to the size of the abnormal *X* chromosome which can be either larger or smaller than normal[4]. If the sex chromatin can be formed only by inactivated, heteropycnotic *X* chromosomes, then the structurally abnormal *X* chromosome in cells from these heterozygous females undergoes preferential inactivation. We have demonstrated the consistent inactivation of an isochromosome-*X* in human leucocytes heterozygous for this structurally abnormal *X* chromosome by means of an autoradiographic examination of chromosome duplication (DNA replication)[5].

For this investigation reported here, peripheral blood containing leucocytes with this abnormal complement was obtained from a 40-year-old woman. She had primary amenorrhœa and sexual infantilism as well as many other anomalies of the type frequently seen in Turner's syndrome. Approximately 20 per cent of the chromatin positive nuclei from the oral mucosa contained two sex chromatin masses. Both the sex chromatin masses in the epithelial cells and the drumsticks in the neutrophils were of two sizes. They were either normal or enlarged[6]. However, there were only two clearly evident cell lines in cultured leucocytes. One cell line had 45 chromosomes with an *XO* sex chromosome complement. The other cell line had 46 chromosomes with an *X*-isochromosome-*X* sex chromosome complement. Since the isochromosome-*X* was larger than the other *X* chromosome in the latter cell line and could be clearly identified, we examined the replication patterns of these two *X* chromosomes in a series of cells in order to find out whether the isochromosome *X* always had the late-replication pattern characteristic of heteropycnotic, inactive *X* chromosomes[7-13]. Leucocyte cultures were prepared[14]. Tritiated thymidine and colchicine were added to a final concentration of 1 μc./ml. (specific activity 0·36 c./mM) and 10^{-6} M respectively. Five hours or nine hours later, metaphase cells were collected directly from the isotope-containing medium. The procedure is described more fully elsewhere[11]. The metaphase figures were photographed before stripping film (Kodak '*AR*-10') or emulsion (Kodak '*NTB*-3') was applied, and re-photographed at the plane of the silver grains overlying the labelled metaphase figures after exposure and development of the photographic emulsion. Under these conditions, the more heavily labelled chromosomes were those which terminated replication late in the synthetic period of interphase.

The isochromosome *X* was the most heavily labelled chromosome in the complement in 12 labelled cells illustrating the end of synthesis of DNA which were examined and karyotyped (Fig. 1). The normal-sized *X* chromosome always terminated DNA replication earlier than the late-replicating isochromosome *X*. This may indicate that the abnormal *X* chromosome was always inactivated in preference to the structurally normal *X* chromosome in these leucocytes. On the other hand, if inactivation of *X* chromosomes occurs very early in embryonic life, the isochromosomes-*X* might be inactivated in a given individual by chance alone in every one of the few cells from which all the leucocytes afterwards arise. Other females heterozygous for a structurally abnormal *X* chromosome have now been examined[15-17]. In cultured leucocytes from these individuals, the isochromosome-*X* was consistently the late-replicating *X* chromosome. A much stronger case can therefore be made for preferential or non-random inactivation of the abnormal *X* chromosome. It is still possible that inactivation of *X* chromosomes occurs at random, and that cells in which the normal *X* chromosome is inactive are inviable.

The results obtained in the work recorded here do not provide any simple explanation for the complex sex chromatin pattern seen in this patient, who is both chromatin-two positive and has sex chromatin bodies of two different sizes. Since there appears to be a consistent relationship between the maximum number and size of sex chromatin masses and the number and size of *X* chromosomes[4], this patient should either be chromatin positive, with every sex chromatin mass enlarged, or there should be at least two more cell lines in this patient than we have been able to demonstrate by culturing leucocytes. A cell line with two normal *X* chromosomes would account for the presence of sex chromatin masses of normal size.





Figs. 1 (above) and 2 (below). Mitotic figures from a leucocyte culture which contained tritiated thymidine for its final 5 h. Each mitotic figure has been photographed before, as well as after, the application of photographic emulsion. Karyotypes have been prepared from the matched photographs. The isochromosome *X* (arrow) is consistently more heavily labelled (late-replicating) than any other chromosome. The isochromosome is also frequently at the periphery of the metaphase figure, as shown here

A cell line with three *X* chromosomes, two being isochromosomes, would account for the presence of cells with two large sex chromatin masses. One possible *XX* sex chromosome complement has been observed among the 42 karyotypes of labelled metaphase figures from cultured leucocytes which have been examined. No metaphase figure with three *X* chromosomes has been observed. If such a cell line exists in this individual, it may be present only in some tissues. An autoradiographic examination of dividing cells from cultures of another tissue such as skin or mucosa, in which the sex chromatin pattern and the karyotype with its replication pattern can be directly compared might resolve the apparent discrepancy between these characteristics.

An examination of the labelling patterns of the autosomes in this *X*-isochromosome *X* complement is in progress. The labelling patterns of the autosomes will be compared with the labelling patterns of the autosomes in *XX*, *XXX*, and *XXXXY* genotypes. In the *XXX* and *XXXXY* complements, the autosomes have a characteristic pattern of DNA replication, which is indistinguishable from that seen in *XX* complements[11,13].

VIROLOGY

Pigs and Rift Valley Fever

One of the earliest papers[1] on Rift Valley fever included pigs in the list of refractory species because Daubney, Hudson and Garnham[2] had failed to elicit a clinical response in two pigs they had injected. Later, however, Weiss[3] directed attention to the circumstantial field evidence that sows had aborted on farms in South Africa where sheep had died. Nevertheless, when Easterday, Murphy and Bennett[4] injected three young pigs intraperitoneally with doses of $10^{2\cdot2}$ and $10^{3\cdot2}$ mouse LD_{50} of Rift Valley fever virus there was no clinical response, no viræmia and no development of antibody. Preliminary findings, herein recorded, suggest that the innate resistance of pigs is not absolute, the dose of virus being critical.

Six immature Large White pigs, weighing 34–45 kg, were split into two groups. The pigs in the first group were injected intravenously with 1·0 ml. of a dilution of infected sheep serum estimated to contain 10^2–10^3 hamster LD_{50} of the van Wyk strain of Rift Valley fever virus. Those in the second group were injected similarly with 10^5–10^6 hamster LD_{50} virus. Simultaneously the infected sheep serum was titrated in hamsters.

The pigs were bled at intervals of two days until the 14th day after inoculation and each serum was injected intraperitoneally into four hamsters. The hamsters were observed for 14 days, after which the survivors were challenged with Rift Valley fever virus. Finally, on the 21st day after inoculation, the serum of each pig was checked for the presence of Rift Valley fever antibodies by neutralization tests in hamsters.

The pigs remained healthy. Neither virus nor antibody was detected in the pigs given the lower dose, but virus was recovered on the 2nd and 4th days after inoculation from one pig given the higher dose. Antibodies were detected in the sera of all three pigs given the higher dose.

Shortening by Actinomycin *D* of Latent Period of Multiplication of Sendai Virus

It has been shown earlier that actinomycin *D* inhibits the multiplication of influenza viruses without any influence on Newcastle disease virus and Sendai virus multiplication[1,2]. It was found that the dynamics of Sendai virus reproduction in actinomycin-treated cultures of chicken fibroblasts and human amniotic cells were changed after the latent period of multiplication was shortened by 2 h (Fig. 1). To clarify this problem an autoradiographic investigation was carried out. Cultures of human amniotic cells infected with Sendai virus (1,000 ID_{50} per cell) were held at 35° C in Medium 199 or in this medium with 0·5 γ/ml. of actinomycin *D*. 30 min, 1, 2, 3 and 5 h after onset of incubation samples of cultures were exposed to 1 μc/ml. of tritiated uridine for 30 min, washed in BBS containing excess of unlabelled uridine, fixed in Carnoy solution, covered with emulsion type *M* and exposed for 1 month. Developed autographs were stained by the Unna method.

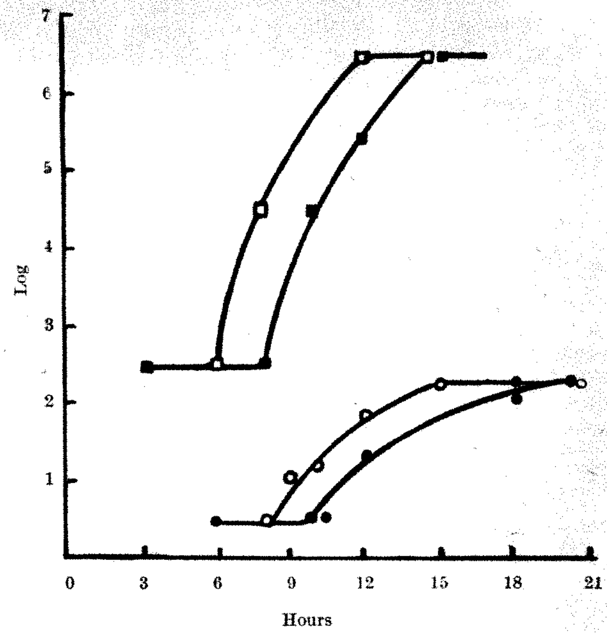

Fig. 1. Influence of actinomycin *D* on the dynamics of Sendai virus reproduction in human amniotic cells
●, HA titre in control cells; ○, HA titre in actinomycin-treated cells; ■, ID_{50} titre for chicken embryos in control cells; □, ID_{50} titre in actinomycin-treated cells

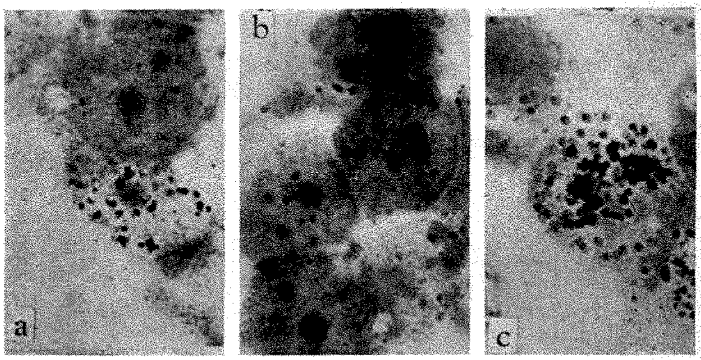

Fig. 2. Human amniotic cells: autoradiographs (× 900)
a, Control cells; *b*, actinomycin-treated cells; *c*, actinomycin-treated cells 2 h after Sendai virus infection

Four sets of experiments were performed: (*a*) control cultures; (*b*) cultures treated with actinomycin *D*; (*c*) infected cultures; (*d*) infected cultures treated with actinomycin *D*. All incorporated radioactivity in the control cells was localized in the cell nuclei, mainly in the internucleolar area; in some cells grains were found both in the internucleolar area and in the nucleoli (Table 1 and Fig. 2). Actinomycin *D* inhibited completely incorporation of tritiated uridine into the internucleolar area and partially into the nucleoli. No differences were observed in grain localization between control cells and infected cells for the first hour after infection; but 2 h after infection and later there was no labelling of internucleolar area. Heavy labelling of nucleoli was observed 3 h after infection (Fig. 2) and disappeared within 5 h. In the infected cells treated with actinomycin *D* no labelling of the internucleolar area was seen; an increased incorporation of tritiated uridine into nucleoli was observed 1 h after infection, became more intense at 2 h and disappeared 3 h after infection. The number of grains in nucleoli of infected cells was considerably greater than that in nucleoli of the control cells.

The results obtained show that actinomycin *D* inhibits the synthesis of RNA in internucleolar area and partially in nucleoli. Differences between our results and those of Perry[3,4] seem to be explained either by different properties of cultures used or by different experimental conditions.

Table 1. Percentage of Human Amniotic Cells labelled with Tritiated Uridine

Intervals after infection	Experimental							
	Control cells		Actinomycin-treated cells		Infected cells		Actinomycin-treated infected cells	
	N	*n*	*N*	*n*	*N*	*n*	*N*	*n*
30 min	70 ± 3·6	13 ± 2·8	0	9 ± 1·6	65 ± 2·6	11 ± 2·4	0	2 ± 1·1
1 h	52 ± 4·0	5 ± 1·7	0	4 ± 1·6	74 ± 3·6	4 ± 1·6	0	18 ± 2·0
2 h	49 ± 4·0	13 ± 2·6	0	6 ± 1·4	0	2 ± 1·1	0	44 ± 4·0
3 h	65 ± 2·6	9 ± 1·6	0	0	0	34 ± 2·6	0	3 ± 1·3
5 h	61 ± 4·0	5 ± 1·7	0	± 1·3	0	9 ± 1·6	0	6 ± 1·4

N, nucleus excluding nucleoli; *n*, nucleolus

Action of Sendai virus on the cells was similar to that of actinomycin *D*; but virus-induced inhibition of nuclear RNA synthesis was observed only 2 h after infection. The synthesis of viral RNA occurred 3 h after infection and was localized in nucleoli where RNA of the Sendai virus inoculum penetrates[5,6]. An earlier synthesis of viral RNA and shortening of the latent period of multiplication by 2 h in actinomycin-treated cultures may be explained by inhibition of messenger RNA of a cell; as a result, enzymatic systems start to work earlier according to a genetic programme of virus.

Nicotinamide Adenine Dinucleotide and Nicotinamide Adenine Dinucleotide Phosphate Concentrations in Leaves of *Nicotiana glutinosa* infected by Tobacco Mosaic Virus

When leaves of *Nicotiana glutinosa* are inoculated with tobacco mosaic virus (TMV) the formation of local necrotic lesions is accompanied by an increase in the rate of respiration[1,2]. This increase is related to the development of the lesions and to the total number of lesions produced. Although tissue extracts of the lesions show increased polyphenoloxidase activity[3,4] evidence is lacking to show that polyphenoloxidase is concerned in the respiration of the intact virus-infected cell or that the increased repiration is related to increased polyphenoloxidase activity. Two possible functions for polyphenoloxidase in the metabolism of the virus-infected cell can be suggested. It may function as a terminal oxidase, and the increased respiration is the result of the increased polyphenoloxidase activity. However, this is most unlikely as the respiration rate in plant tissues is not usually limited by the activity of the terminal oxidases. A second possibility is that increased polyphenoloxidase activity is concerned with the oxidation of polyphenolic compounds to oxidized polyphenols. If this made any significant contribution to the respiration of the virus-infected tissue an increase in the respiratory quotient would be expected, but this was shown not to be so by Yamaguchi and Hirai[2] who found in *N. glutinosa* leaves infected by TMV the respiratory quotient was unchanged.

In looking for an explanation of the increased respiration rate of *N. glutinosa* leaves showing local lesions formed as a result of TMV-infection, nicotinamide-adenine dinucleotide (NAD), reduced nicotinamide-adenine dinucleotide ($NADH_2$), nicotinamide-adenine dinucleotide phosphate (NADP) and reduced nicotinamide-adenine dinucleotide phosphate ($NADPH_2$) concentrations in the leaves were determined.

Leaves of *Nicotiana glutinosa* were inoculated with TMV and five days after the appearance of local lesions healthy and infected leaves were assayed for NAD, $NADH_2$, NADP and $NADPH_2$. An acid medium of 5 ml. of 0·1 M *tris*-hydrochloric acid buffer *p*H 8·2, 1 ml. N hydrochloric acid and 2 ml. water was used to extract NAD and NADP. $NADH_2$ and $NADPH_2$ were extracted by an alkaline medium, 5 ml. *tris*-hydrochloric acid buffer, 1 ml. N sodium hydroxide and 2 ml. of water. The extraction medium was contained in a Potter–Elvehjem homogenizer immersed in a bath of boiling water. The leaf was cut into pieces of convenient size and rapidly dropped into the homogenizer, heated for 30 sec, homogenized for 90 sec, and then rapidly cooled by immersion in a freezing mixture of dry-ice and ethanol. The extracts were thawed and centrifuged at 20,000*g* for 15 min in a refrigerated centrifuge. The supernatants were decanted; the *p*H of the alkaline-extract adjusted to 8·0 and that of the acid-extract to 7·5 by dropwise addition of acid or alkali in the cold. The nicotinamide-adenine dinucleotide content of the extracts was determined immediately by the colorimetric method of Slater and Sawyer[5]. NAD, $NADH_2$, NADP, and $NADPH_2$ (Sigma purest grade) were tested for purity by the usual spectrophotometric methods[6] and used to construct calibration curves for the method of Slater and Sawyer and to determine the recovery of dinucleotides added to the extracting medium. The recovery was more than 90 per cent for all four dinucleotides.

Table 1. NICOTINAMIDE-ADENINE DINUCLEOTIDE AND NICOTINAMIDE-ADENINE DINUCLEOTIDE PHOSPHATE CONCENTRATION OF *Nicotiana glutinosa* LEAVES INOCULATED WITH TMV

Nucleotide	μg/g fresh weight	
	Healthy	TMV-infected
NAD	5·5	4·1
$NADH_2$	0·8	1·7
NADP	3·0	1·0
$NADPH_2$	0·2	0·7
Total	9·5	7·5

The results given in Table 1 show an increase in the level of $NADH_2$ and $NADPH_2$ in the leaves showing TMV-induced lesions. As these results represent a complete leaf it may be that the increase in reduced nicotinamide-adenine dinucleotides is even greater in the region of the local lesion. It is not possible to cut out and assay a number of individual local lesions because the tissue contains an active $NADH_2$ oxidase which rapidly oxidizes $NADH_2$ in tissue homogenates. The decrease in the $NAD/NADH_2$ ratio in the tissue from 7 to 1 for healthy leaves to 2·4 to 1 for virus-infected leaves and a decrease from 15 to 1 for healthy to 1·4 to 1 in the virus-infected leaves for the $NADP/NADPH_2$ ratio show an accumulation of reduced nicotinamide-adenine dinucleotides in the virus-infected leaf. It has been shown by Solymosy and Farkas[7] that the enzymes of the pentose phosphate shunt are activated in the periphery of the local lesion. This may account for the increase in $NADPH_2$ in the virus-infected tissue. However, an increased respiration rate in the tissue requires an increase in electron transfer from $NADH_2$ to oxygen. It may be that virus multiplication in the lesion results in protein synthesis leading to an increased utilization of adenosine triphosphate and concomitant oxygen uptake. Even so it would appear that the electron-transfer chain is unable to reoxidize reduced nicotinamide-adenine dinucleotides as rapidly as they are formed in the virus-induced local lesion.

MISCELLANEOUS

Equipment for Facilitating Movement on an Intertidal Mud-flat

It is probable that the lack of literature relating to intertidal mud ecology as compared with other intertidal habitats is due, in part, to the restrictions placed on movement by the softness of the substratum. Yonge[1] reported that at Stolford, Bridgewater Bay, the shrimp fishermen, whose nets were secured on soft banks of mud, used a type of sledge or 'mud-horse', which they pushed in front of them. The sledge served the double purpose of preventing them from sinking deeply into the mud and of carrying back the catch. Barnett (personal communication) used mud shoes of his own design to aid movement.

Ecological investigations on littoral muds often necessitate travelling for distances of several hundred yards, and then remaining in one position for periods of several minutes while samples are taken. The problem of performing these tasks has been overcome by designing mud skis.

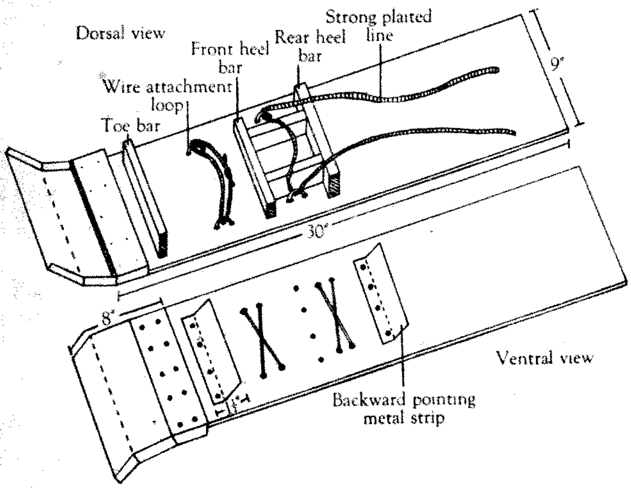

Fig. 1. Diagrammatic sketch of the mud skis

The main body of each ski is of ¼-in. thick 3-ply wood, 30 in. long and 9 in. wide, to which are attached a toe, front heel, and a rear heel bar (Fig. 1). These wooden bars prevent fore and aft movement of the foot relative to the ski, bars on either side of the heel eliminating sideways movement. The upturned forward end of the ski is fashioned from 18 gauge galvanized iron, as are the backward pointing strips on the ventral surface. For extra strength the galvanized attachments and wooden bars are fixed to the 3-ply board with ¾ in. brass screws. The ski is fastened to the foot in two places by means of strong plaited line threaded through attachment loops made from ⅛-in. diameter galvanized wire.

Forward movement is effected by using one ski as a pivot, sliding the other ski forward relative to it, then using this ski as a pivot. The backwardly directed metal strips on the underside of the pivot ski prevent slipping.

This method of progression allows a sledge laden with sampling equipment to be drawn along by hand.

Impurities in Commercially Prepared Tritiated Folic Acid

RADIOISOTOPICALLY labelled compounds are being used with increasing frequency in both basic science and clinical investigation. Most laboratories are dependent on commercial sources for these products, and although the specifications attesting to the purity of a compound are usually accurate, exceptions do occur.

We have recently had occasion to use commercially available tritiated folic acid specified by the manufacturer to be 100 per cent pure by dilution analysis and chromatography. As a check on the purity a sample of the tritiated folic acid was subjected to paper chromatography in subdued light, using 0·2 M phosphate buffer *p*H 7·0. Fig. 1 is a photograph taken under ultra-violet illumination of the chromatograms of the tritiated folic acid as well as unpurified and purified stable folic acid. Strip *A* is the tritiated folic acid with accompanying radioscanogram. Radioactivity is clearly evident at several positions corresponding to two slow-moving fluorescent areas, a middle absorbent area representing folic acid, a second faster-moving fluorescent area, and a less-clearly visible absorbent spot near the end of the strip. Strip *B* is unpurified grade *C* folic acid. Similar slow-moving fluorescent areas are evident, but the fluorescence just ahead of the folic acid absorbent spot is moving slower than that seen in the tritiated folic acid strip. However, this impurity on repeat chromatography sometimes spreads from the folate absorbent area, and, therefore, probably represents the same impurity. Strip *C* is the same commercial folic acid purified in our laboratory by the method of Sakami and Knowles[1]. Practically all but a slight trace of the faster-moving fluorescent impurity has been removed. We did not analyse these impurities, but from the observations of Belcher *et al.*[2] it would appear that the faster-moving fluorescent area seen in strip *A* represents free tritium and/or para-aminobenzylglutamates. The slower-moving fluorescent areas are probably pteridine fractions. The fluorescent areas at the end of the strips are due to accumulation of phosphate salts at the solvent front.

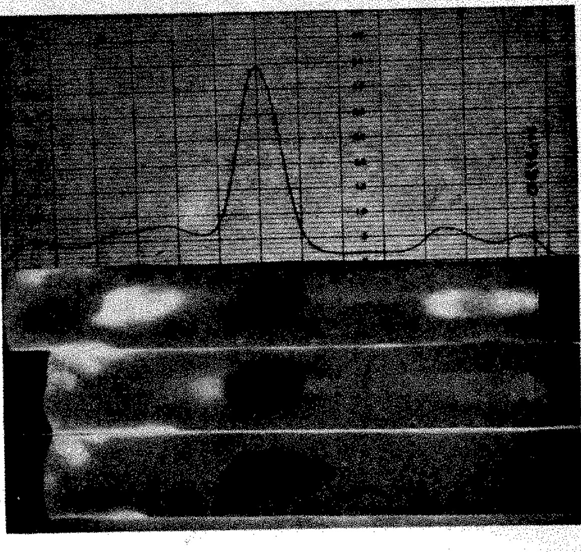

Fig. 1

Planimetric analysis of the tritiated folic acid radioscanogram revealed that only 50 per cent of the radioactivity corresponded to the folic acid absorbent area. The slow- and fast-fluorescent areas had approximately 15 and 35 per cent of the radioactivity, respectively.

The pure folate absorbent area was easily eluted from the paper with 0·2 M phosphate buffer, *p*H 7, and, when rechromatographed under similar conditions, moved as a single radioactive peak corresponding in mobility to pure folic acid.

This work was supported by a New York City Health Research Council grant *U*–1190.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, December 2

University of London (at the Royal Veterinary College, Royal College Street, London, N W 1), at 4 p m —Prof John Francis (University of Queensland) "Veterinary Research and Education in Australia" *

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W C 2), at 5 30 p m —Mr F Horner "Atmospheric Radio Noise as a Problem in Radio Communications"

British Institution of Radio Engineers, Computer Group (joint meeting with the Computer Group of the Institution of Electrical Engineers, at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 p m —Symposium on "Analogue Circuit Techniques Using Transistors"

Institution of Mechanical Engineers, Education and Training Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m — Discussion on "Some Experience on Projects in Courses for Diplomas in Technology"

Royal Society of Arts (at John Adam Street, Adelphi, London, W C 2), at 6 p m —Mr Hulme Chadwick "Colour and Community" (Last of three Cantor Lectures on "Colour in Modern Life")

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Mr H R Hearn "Technical Developments in the Aerosol Field"

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 8 15 p m —Mr Norman G Dyhrenfurth "America on Everest".

Tuesday, December 3

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Dr P J Ucko "The Significance of Prehistoric Human Figurines" *

University of London (at Imperial College, London, S W 7), at 1 30 p m —Mr D E Broadbent "Decision and Action" (Last of five lectures on "The Basis of Experimental Psychology")*

Institution of Civil Engineers (at Great George Street, Westminster, London, S W 1), at 5 30 p m —Mr J C Dickinson and Mr R T Gerrard "Cameron Highlands Hydroelectric Scheme"

Institution of Electrical Engineers, Science and General Division (at Savoy Place, London, W C 2), at 5 30 p m —Mr R M Ware and Mr D J McNeil "Iron Disilicide as a Thermoelectric Generator Material", Dr K Crystal "Silicon Solar Cells for Ground Level Use"

University of London (at Imperial College, London, S W 7), at 5 30 p m —Prof A V Bradshaw "The Third Phase in Metallurgy" (Inaugural Lecture)

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m — Dr F T Perkins "Virus Vaccines—Living or Dead ?" (Fourteenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

Society for Analytical Chemistry, Atomic Absorption Spectroscopy Discussion Panel of the Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 6 30 p m —First Annual General Meeting, followed by a Discussion opened by Dr W Slavin (U S A)

Wednesday, December 4

University of London (at the Postgraduate Medical School of London, Du Cane Road, London, W 12), at 2 p m —Prof A Latner "Isoenzymes" *

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W C 2), at 2 30 p m and 5 30 p m —Colloquium on "Connections in Electronic Circuits"

Royal Society of Arts (at John Adam Street, Adelphi, London, W C 2), at 2 30 p m —Dr B A Southgate "The Prevention of Water Pollution—the Present Position"

Colour Group (Great Britain) (in the new Physics Department, Imperial College, London, S W 7), at 3 p m —Mr J Charlton "The Use of Colour in Eighteenth Century Interiors" 4 p m —Continued Discussion of the C I E Conference Reports with an Introduction by Dr R W G Hunt.

Institute of Petroleum (at 61 New Cavendish Street, London, W 1), at 5 30 p m —Dr T F Gaskell "The Study of Oceanography and Its Bearing on Exploration for Oil"

Institution of Electrical Engineers, Power Division (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Electrical Aspects of the Offices, Shops and Railway Premises Bill" opened by Mr J R Freeth

British Institution of Radio Engineers, Television Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 p m —Symposium on "New Developments in Television Cameras and Zoom Lenses"

Institution of Mechanical Engineers, Steam Plant Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Mr R S Silver "An Approach to a New Theory of Surface Condensers"

Plastics Institute (at the Wellcome Building, Euston Road, London, N W 1), at 6 30 p m —Mr J M J Estevez "Some Thoughts on the Weathering and Ageing of Plastics"

Society for Analytical Chemistry (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 7 p.m —Meeting on "Differential Thermal Analysis"

Thursday, December 5

Nutrition Society (joint meeting with the British Grassland Society, at the Federation of British Industries, 21 Tothill Street, London, S W 1)—Symposium on "The Utilization of Grass by Ruminants"

Royal Society (at Burlington House, Piccadilly, London, W 1), at 4 30 p m —Mr N W Pirie, F R S "The Size of Small Organisms" (The Leeuwenhoek Lecture)

Sir Thomas Middleton Memorial Trust (at the Wellcome Building, 183 Euston Road, London, N W 1), at 5 p m —Dr J B Brooksby "The Impact of Research on the Control of Foot-and-Mouth Disease" (Ninth Middleton Memorial Lecture)

Institution of Civil Engineers (at Great George Street, Westminster, London, S W 1), at 5 30 p m —Informal Discussion on "Supersonic Concorde Aircraft—Their Effect on Airport Layout" introduced by Mr A C Johnson

Royal Institution, Library Circle (at 21 Albemarle Street, London, W 1), at 5 30 p m —Dr F N L Poynter "On Collecting Books for a Library of the History of Medicine"

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m — Prof L Saunders "Interfacial Films and Cell Membranes" (Fifteenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

Institute of Refrigeration (at the National College for Heating, Ventilation, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S E 1), at 6 p m —Mr V S Meadows "Fluidised Bed Techniques in Refrigeration"

Institution of Mechanical Engineers, Hydraulic Plant and Machinery Group (at 1 Birdcage Walk, Westminster, London, S W 1) at 6 p m —Discussion on "Should Hydraulic Equipment be Cheaper ?"

Society of Chemical Industry, London Section (joint meeting with the Industrial Water and Effluents Group, at the Royal Institution, Albemarle Street, London, W 1), at 6 30 p m —Dr J S Carter "The Alkali Inspectorate Look Back"

Royal Institute of Chemistry, London Section (joint meeting with the Northampton College of Advanced Technology Chemical Society, at the Northampton College of Advanced Technology, St John Street, London, E C 1), at 7 p m —Prof G J Hills "The Structure of Water and Aqueous Solutions"

Friday, December 6

Association of Applied Biologists (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, London, S W 7), at 11 a m — Discussion on "Host Specific Replanting Problems in Fruit Trees" introduced by Dr R S Pitcher and Dr J E Crosse 12 noon—Discussion on "Viruses in the Cultivated Mushroom" introduced by Mr M Hollings, Miss Doreen G Gandy, Dr F T Last and Dr Olwen M Stone 2 30 p m —Dr L Broadbent "Winds of Change in Applied Biology" (Barnes Memorial Lecture)

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m — Dr L S B Leakey "The Search for Man's Ancestors and Cousins in East Africa"

Saturday, December 7

London County Council (at the Horniman Museum, London Road Forest Hill, London, S E 23), at 3 30 p m —Dr G H S Bushnell "Pre-Columbian Mexican Art" *

Monday, December 9

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London, W C 1), at 5 30 p m —Dr I Hacking "On the Foundations of Statistics"

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Measurements at Very Low Frequencies with particular reference to Noise" opened by Dr J L Douce Mr H Sutcliffe and Prof J C West

Institution of Electrical Engineers, Science and General Division (at Savoy Place, London, W C 2), at 5 30 p m —Dr F Fallside and Mr M R Patel "Effect of a Back E M F Non-linearity on Responses of a Second-Order Position Control System", Dr F Fallside and J O C Ezeilo "Application of the Second Method of Lyapunov to the Stability of Certain Position Control Systems Containing a Back-E M F Non-linearity"

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 6 p m —"The Pitcairn People" (colour films).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturer/Lecturer (well qualified in one of the human biological sciences) in Ergonomics—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire, quoting Ref 36/G (December 6)

Lecturer (with industrial experience in the field of corrosion and surface technology, and preferably an honours degree or equivalent qualifications) in the Department of Metallurgy—The Secretary, Battersea College of Technology, Battersea Park Road, London, S W 11 (December 6)

Senior Research Assistant (with a Ph D in physics or equivalent research experience) in the Department of Physics, to work on the optical and electrical properties of some magnetic oxide semi-conductors, this will include the Raman effect, using an infra-red gas laser—The Registrar, The University Sheffield (December 7)

Tutor in Philosophy—The Principal, St Anne's College, Oxford (December 7)

Assistant Librarian (honours graduate with library qualifications)—The Secretary, The Queen's University, Belfast, Northern Ireland (December 10)

Assistant Lecturer or Demonstrator (with medical qualifications registrable in the United Kingdom) in Pathology—The Registrar, The University, Manchester 13 (December 14)

Chair of Statistics—The Registrar, The University, Sheffield (December 14)

Senior Research Associate (plant physiologist or physical scientist interested in plant physiological problems) in the School of Biological Sciences, to work under the general direction of Prof J Dainty on a programme of ionic and water relations of plant cells and tissues—The Registrar, University of East Anglia, Earlham Hall, Norwich, Nor 05G (December 16)

Senior Lecturer or Lecturer in Ophthalmology—The Registrar, The University, Sheffield (December 18)

Senior Lecturer or Lecturer in Geography at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 20)

Senior Lecturer or Lecturer in Pharmacology at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 20)

Senior Lecturer (with a degree in chemistry or biochemistry and extensive experience in clinical chemistry) in the Department of Clinical Chemistry—The Secretary, The University, Edinburgh (December 21)

Assistant Lecturer in the Department of Zoology, University of Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 22)

Deputy Chief Scientific Officer (Virologist) to take charge of the Virology Section of the Microbiological Research Establishment, Porton Down, Wilts, and to undertake research in the field of animal viruses, particularly those groups which attack man, and to supervise the work of a group of scientific staff working in allied fields—The Secretary, Civil Service Commission, 23 Savile Row, London, W 1, quoting Ref S/5790/63 (December 31)

Lecturer (qualified in physics and an interest in the application of physical techniques to biology and particularly macromolecules or electron microscopy) in the Department of Botany—The Secretary, University College, Gower Street, London, W C 1 (December 31)

Lecturer (with a special interest in gas dynamics) in the Department of Mechanical Engineering—The Secretary, University College, Gower Street, London, W C 1 (December 31)

Senior Lecturer in Experimental Physics, and a Lecturer and an Assistant Lecturer in Experimental or Theoretical Physics—The Registrar, University of Sussex, Stanmer House, Stanmer, Brighton (December 31)

Reader or Senior Lecturer in Chemistry, and a Lecturer and an Assistant Lecturer in Chemistry—The Registrar, University of Sussex, Stanmer House, Stanmer, Brighton (December 31)

Marguerite A Keasbey Official Fellow and Lecturer in Theoretical Physics—The Warden, New College, Oxford (January 1)

Chair of Applied Electromagnetism, with particular reference to plasma engineering—The Registrar, The University, Liverpool, quoting Ref No CV/462 (January 11)

Chair of Public Health and Social Medicine—The Secretary, The University, Edinburgh (January 15)

Senior Lecturer or Lecturer in Entomology at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Commonwealth Universities (Branch Office) Marlborough House, Pall Mall, London, S W 1 (South Africa and London, January 15)

Chair of Mathematical Statistics at Monash University—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1, or The Registrar, Monash, University, P O Box 92, Clayton, Victoria, Australia (Australia and London, January 31)

University Lecturer in Biochemistry—The Administrator, Department of Biochemistry, The University, South Parks Road, Oxford (January 31)

Assistant or Assistant Lecturer (with special interests in inorganic chemistry) in the Department of Chemistry—The Professor, Department of Chemistry, University College, Upper Merrion Street, Dublin 2, Republic of Ireland

Lecturer in Mathematics, and an Assistant Lecturer in Zoology at the University of Basutoland, Bechuanaland Protectorate and Swaziland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1

Lecturer (with good academic qualifications and preferably experience of teaching, research or industry) in Mathematics—The Academic Registrar, Loughborough College of Technology, Loughborough, Leicestershire quoting Ref 35/G

Physicist (with experience of electronics), to work in the application of computers to experiments in the field of nuclear structure—Nuclear Physics Laboratory, The University, 21 Banbury Road, Oxford

Electrophoresis Apparatus
TISELIUS MOVING BOUNDARY TYPE

★ Large capacity research instrument with great versatility of application—for diffusion experiments, analytical electrophoresis using a range of volumes, and large-scale preparative work.

★ New straight line optics affording compact overall size, and permitting independent two-cell operation

★ Outstanding optical systems giving highest definition for all measuring methods including phase plate and interference diagrams.

★ Far reaching automation of controls, including semi-automatic photography.

★ Comprehensive range of analytical and preparative cell sets of novel design

★ Thoughtful co-ordination in the design of optical, mechanical and electronic systems giving maximum versatility of application, ease of operation and facility for instantaneous changeover from one optical method to another during an experiment.

Applications will be considered for similar vacancies occurring later Appointments vary from 3 to 12 months in duration Salaries range between £3,000 to £4,000 a year, plus generous allowances All emoluments tax-free

For job description write to DEPARTMENT OF TECHNICAL CO-OPERATION, International Recruitment Unit, Eland House, Stag Place, Victoria, London, S W 1, quoting RC 344/02 (AEA) and stating post(s) applied for

BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

Notice is hereby given that an election of Junior Fellows to begin work on October 1 next will take place in May, 1964 Junior Fellowships have annual values of £1,100 to £1,500, plus yearly increments of £100, for three years As a rule, superannuation benefits are provided to which the successful candidate will be required to contribute 5 per cent of the annual stipend and to which the Trust will make a contribution of 10 per cent Candidates must have taken a degree in a faculty of a university approved by the Trustees in Her Majesty's Dominions, Protectorates and Mandated Territories, India, Pakistan and the Republic of Ireland, or a medical diploma registrable in the United Kingdom Elections to Junior Fellowships are rarely made above the age of 35 years Applications from candidates must be received not later than April 1 Candidates must submit evidence that they can be given accommodation in the departments where they propose to work, which must be either in Great Britain or Ireland

Forms of application and all information, may be obtained by letter only, addressed to Sir Roy Cameron, F R S, Beit Memorial Fellowships for Medical Research, University College Hospital Medical School, University Street, London, W C 1 For Overseas candidates forms of application may be obtained from the Secretary, South African Medical Council, P O Box 205, Pretoria, South Africa The Ministry of Health, The Government of India, New Delhi, India, The Government of East Pakistan, Eden Buildings, Ramna, Dacca, East Pakistan, The Director, Commonwealth Office of Education, Box 3879, Sydney, Australia, The Department of Health, Wellington, New Zealand, and The Canadian Medical Association, 244 St George Street, Toronto, Canada

---

BRITISH AIRCRAFT CORPORATION

GUIDED WEAPONS DIVISION · STEVENAGE

wish to appoint a

DEPUTY LIBRARIAN

Candidates should be Chartered Librarians with qualifications in Science or Engineering or with technical library experience (public, technical college or special)

The duties involved will consist mainly of information work, including co-ordinate indexing of reports, answering technical inquiries, preparing bibliographies, and assisting in an active information dissemination programme

The Corporation operates a comprehensive pension and life assurance plan and housing may be available to the selected applicant

Please apply in writing to

British Aircraft Corporation Limited,
Senior Personnel Officer,
Guided Weapons Division,
Six Hills Way,
Stevenage, Herts.

CHEMISTS

Chemical Abstracts Service of the American Chemical Society has a number of positions for men or women in chemical information work in the following areas

PHYSICAL CHEMISTRY INORGANIC CHEMISTRY
ORGANIC CHEMISTRY POLYMER CHEMISTRY
DOCUMENTATION RESEARCH

These are excellent opportunities for chemists at all levels of experience Good conditions, prospects and pension scheme Salary according to training and experience Interviews may be arranged in London, England Transportation will be furnished

Write to

Mr. E. H. Heilman,
Chemical Abstracts Service,
The Ohio State University,
Columbus 10, Ohio.

UNIVERSITY OF WESTERN ONTARIO

FACULTY OF ENGINEERING SCIENCE

Applications are invited for a National Research Council of Canada Post Doctorate Fellowship from candidates wishing to pursue research in one of the following fields Meteorological aerodynamic and structural aspects of wind loading on structures, geotechnical factors influencing design parameters in unconsolidated earth materials, thermodynamic properties, heat transfer and fluid flow of water in the super critical region, and gas-solid particulate systems or kinetics

Persons should apply at once, giving curriculum vitae, details of research interests and experience and the names of referees

TIMBER RESEARCH AND DEVELOPMENT ASSOCIATION

Requires Graduate Physical or Inorganic Chemist with some botanical knowledge for research on surface coatings and preservatives for wood Preferred age range 25 to 30, salary range £850 to £1,100

Apply The Secretary, T R A D A, St John's Road, Tylers Green, High Wycombe, Bucks

---

ST PAUL'S SCHOOL REQUIRES FOR September, 1964, a Master to teach Biology to A level, with some Chemistry and Biology, in the Middle School An interest in the teaching of Science to non-scientists and in the running of the School Field Club would be advantageous —Apply to the High Master, St Paul's School, London, W 14

WELLCOME RESEARCH LABORATORIES

RESEARCH BIOCHEMIST

to join the Therapeutic Research Division of the Wellcome Research Laboratories The Division is concerned with the investigation of substances with pharmacodynamic and chemotherapeutic activity, aiming at the discovery of agents of value in human and veterinary medicine

He will investigate biochemical aspects of the action and metabolism of drugs in close collaboration with biologists and chemists. Graduates, preferably under the age of 30, with relevant postgraduate research experience, are invited to write in confidence for further particulars, quoting ref U 4, to Mr. H. Mendelson, The Wellcome Building, 183 Euston Road, London, N.W 1

AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF ANIMAL HEALTH

RESEARCH BIOCHEMIST

Applications are invited for appointment to a position of Research Officer (Biochemist) with the Organization's McMaster Animal Health Laboratory, situated in the grounds of the University of Sydney, with which a close association is maintained

The appointee will be required to undertake research on some aspects of chemical pathology, particularly in relation to the effects of parasitism

Applicants should possess a Ph D degree or have had postgraduate research experience of equivalent standard and duration supported by satisfactory evidence of research ability Training and experience in mammalian biochemical research would be preferred

Salary Dependent upon qualifications and experience within the range
£A1,674 to £A2,511 per annum (but not less than £A1,979 per annum)

Salary for women will be £A188 per annum less than corresponding rates for men

Promotion within C S I R O is by merit and may go beyond the upper limit of the scale within which the original appointment is made

Fares paid for the appointee and his dependent family Further particulars supplied on application to

Mr P F Butler, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2,

to whom applications (quoting Appointment No 202/214) should be addressed by December 28, 1963

UNIVERSITY OF OXFORD

UNIVERSITY LECTURESHIP IN BIOCHEMISTRY

The University proposes to appoint with effect from as early a date as can be arranged a Lecturer in Biochemistry Stipend in the scale £1,250 (under age 28) to £2,285 or, if medically qualified, £1,610 to £2,450 Children's allowances of £50 per annum for each child, and F S S U

Three copies of applications, with the names of two referees, by January 31, 1964, to the Administrator, Department of Biochemistry, South Parks Road, Oxford, from whom further particulars can be obtained

---

EPSOM GROUP MANAGEMENT COMMITTEE

Senior Biochemist required for the Department of Chemical Pathology in the Group Laboratory at Epsom District Hospital, duties principally in laboratory supervision with opportunities for conducting original work Whitley Council salary and conditions £1,520 to £1,880 per annum

Applications, stating age, qualifications and experience, and giving names of two referees, to Group Secretary, Epsom District Hospital, Epsom, Surrey, as soon as possible

---

SCOTTISH AND NEWCASTLE BREWERIES LIMITED

Young honours (at least Class II) Graduate Chemist or Biochemist, or equivalent (male or female) required for interesting work in process investigation and research relating to brewing and malting in laboratory at Edinburgh Sound appreciation of scientific principles and good practical work is essential Previous experience in brewing not necessary Salary according to age and qualifications Non-contributory Pension Scheme in operation

Applications to Group Chief Chemist, Scottish and Newcastle Breweries Limited, Abbey Brewery, Holyrood Road, Edinburgh, 8

UNIVERSITY OF ABERDEEN

CHAIR OF CHEMISTRY

Applications are invited for a new Chair of Chemistry, within the existing department of Chemistry It is the intention of the University Court that the person appointed should have interests in Organic Chemistry

Further particulars should be obtained from the Secretary, the University, Aberdeen, with whom applications (ten copies), including the names of three referees, should be lodged not later than December 31, 1963

UNIVERSITY OF KHARTOUM

FACULTY OF SCIENCE

Applications are invited for a Senior Lectureship or Lectureship in Mathematics Salary scales Senior Lecturer, £S 2,052 by £S 75 to £S 2 277 per annum , Lecturer, £S 1,227 by £S 75 to £S 2,052 per annum Cost of living allowance approximately £S 180 per annum, at present Outfit allowance £S 50 Family allowances Wife, £S 60 per annum , first child, £S 90 per annum , second and third child, £S 30 per annum, each (£S 1 = £1 0s 6d sterling) Passages for appointee and family on appointment, termination and annual leave There is a superannuation scheme and arrangements can be made to maintain F S S U policies Direct appointment on contract normally for five years with possibility of renewal (secondment welcomed if possible) Unfurnished accommodation provided at rent (excluding rates) up to 7½ per cent of salary

Applications (ten copies), detailing qualifications and experience, and naming three referees by December 20, 1963, to Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained

---

UNIVERSITY OF KHARTOUM

SENIOR LECTURESHIP OR LECTURESHIP IN AGRICULTURAL BOTANY

Applications are invited for a Senior Lectureship or Lectureship in Agricultural Botany Salary scales Senior Lecturers, £S 2,052 by £S 75 to £S 2,277 per annum , Lecturer, £S 1 227 by £S 75 to £S 2 052 per annum Entry point according to qualifications and experience Cost of living allowance approximately £S 180 per annum, at present Outfit allowance £S 50 Family allowances Wife, £S 60 per annum , first child, £S 90 per annum , second and third child, £S 30 per annum, each (£S 1 = £1 0s 6d sterling) Passages for appointee and family on appointment, termination and annual leave Superannuation scheme and arrangements can be made to maintain F S S U policies Appointment on contract for five years with possibility of renewal (secondment welcomed if possible) Unfurnished accommodation provided at rent (excluding rates) up to 7½ per cent of salary

Applications (ten copies), detailing qualifications and experience, and naming three referees by December 20, 1963, to Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained

---

UNIVERSITY OF KHARTOUM

FACULTY OF SCIENCE

Applications are invited for a Senior Lectureship or Lectureship in Physics Salary scales Senior Lecturer, £S 2,052 by £S 75 to £S 2,277 per annum , Lecturer, £S 1,227 by £S 75 to £S 2,052 per annum Cost of living allowance approximately £S 180 per annum, at present Outfit allowance £S 50 Family allowances Wife, £S 60 per annum , first child, £S 90 per annum , second and third child, £S 30 per annum, each (£S 1 = £1 0s 6d sterling) Passages for appointee and family on appointment, termination and annual leave There is a superannuation scheme and arrangements can be made to maintain F S S U policies Appointment on contract normally for five years with possibility of renewal (secondment welcomed if possible) Unfurnished accommodation provided at rent (excluding rates) up to 7½ per cent of salary

Applications (ten copies), detailing qualifications and experience, and naming three referees by December 20, 1963, to Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained

---

McMASTER UNIVERSITY

HAMILTON, ONTARIO

Applications are invited for appointments in the Department of Electrical Engineering Candidates should have an interest in one or more of the following Network Theory , Non-linear Circuits , Communications , Control Systems , Digital Systems A Doctorate in Electrical Engineering is required and industrial research or development experience would be an advantage Duties include teaching at undergraduate and graduate levels, conducting research and supervising graduate students Salary according to qualifications and experience, Floor Salaries Assistant Professor $7,250 , Associate Professor $9,250 , Professor $12,500 Additional stipends for summer research work

Applications and inquiries should be addressed to the Chairman, Department of Electrical Engineering, McMaster University, Hamilton Ontario

THE BRITISH COAL UTILISATION RESEARCH ASSOCIATION

Randalls Road, Leatherhead, Surrey

invites applications from

(1) PHYSICISTS

with high academic qualifications for appointment as

SUPERINTENDENT OF THE PHYSICS DEPARTMENT

in a salary range up to £2,500 per annum or to £2,800 depending on experience

Besides supervising the physics researches, the Superintendent assists the other Basic Research Departments and the Applied Research Departments in the use of physical techniques of measurement and the application of physical principles to their work in combustion, gasification, heat transfer and the other aspects of coal utilisation research

(2) PHYSICISTS AND MECHANICAL ENGINEERS

with a good foundation in heat transfer and fluid mechanics and a thorough knowledge of modern methods of measurement, to work in the Physics Department, or in research teams engaged on bench and pilot scale studies of advanced methods of burning and gasifying coal Starting salaries up to £1,000 per annum will be paid to recent graduates. Applicants with experience may start at a higher salary Able and keen men will be promoted rapidly to career grades, in which salaries can exceed £2,000 per annum. These applicants should be under 27 years of age, with First or Upper Second Class Honours Degrees

The Association operates a contributory superannuation scheme

Applicants for the above posts should write to the Assistant Secretary by January 8, 1964.

AUSTRALIA

COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

DIVISION OF FOOD PRESERVATION

PLANT BIOCHEMIST OR PHYSIOLOGIST

Applications are invited for appointment to a position of Research Officer (Plant Biochemist or Physiologist) with the Organization's Division of Food Preservation

The appointee will be located at the Plant Physiology Unit in the Department of Biological Sciences at the University of Sydney This Unit, operated jointly by the Division and the University, conducts research in the physiology, biophysics, and the biochemistry of plant tissues Current research interests of the Unit include the replication and growth of chloroplasts, photosynthesis, the mechanism of respiratory control, organic acid metabolism, and the electro-physiology of plant cell membranes

Applicants should possess a Ph D degree in biology or biochemistry or have had post-graduate research experience preferably in plant biochemistry or physiology, of equivalent standard and duration supported by satisfactory evidence of research ability

Salary Dependent upon qualifications and experience within the ranges
£A1 674 to £A2,511 per annum (but not less than £A1,979 per annum) or
£A2,655 to £A3,015 per annum

Salary for a woman will be £A188 per annum less than corresponding rates for men

Promotion within C S.I R O is by merit and may go beyond the upper limit of the scale within which the original appointment is made

By mutual arrangement, the appointment may be for an indefinite period or for an initial fixed term of three years

Fares paid for the appointee and his dependent family and return fares to point of origin will be paid for an appointee who accepts appointment for a fixed term Further particulars supplied on application to

Mr P P Butler, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House Kingsway, London, W C 2,

to whom applications (quoting Appointment No 300/377) should be addressed by December 28, 1963

UNIVERSITY COLLEGE OF RHODESIA AND NYASALAND

MEDICAL SCHOOL

SENIOR LECTURESHIPS OR LECTURESHIPS IN ANATOMY (INCLUDING HISTOLOGY) PHYSIOLOGY (INCLUDING BIOCHEMISTRY)

Applications are invited for the above Lectureships in connection with the new Medical School of the University College of Rhodesia and Nyasaland. The School provides courses leading to the M B , Ch B degree of the University of Birmingham The first intake of students was in 1963 Salary scales . Assistant Lecturer, £1,200 by £50 to £1,350 , Lecturer, Grade II, £1,450 by £70 to £1,800 , Lecturer, Grade I, £1 880 by £80 to £2,200 , Senior Lecturer, £2 100 by £100 to £2,600 Passages to Salisbury for appointee, wife, and dependent children on appointment, with allowance for transport of effects Installation grant of £100 in addition for persons recruited from outside Africa Superannuation and medical aid schemes Unfurnished accommodation at rent of 15 per cent of salary Assistance given for triennial visits overseas

Detailed applications (six copies), naming three referees, should be sent not later than January 15, 1964, to the Assistant Registrar, The Medical School, Birmingham 15, from whom further particulars may be obtained

---

UNIVERSITY OF KHARTOUM

FACULTY OF PHARMACY

Applications are invited for a post of Senior Lecturer or Lecturer in Pharmacology Salary scales Senior Lecturer, £S 2,052 by £S 75 to £S 2,277 per annum . Lecturer, £S 1,227 by £S 75 to £S 2,052 per annum Cost of living allowance approximately £S 180 per annum, at present Outfit allowance £S 50 Family allowances Wife £S 60 per annum , first child, £S 90 per annum , second and third child, £S 30 per annum, each (£S 1 = £1 0s 6d sterling) Passages for appointee and family on appointment, termination and annual leave There is a superannuation scheme and arrangements can be made to maintain F S S U policies Direct appointment on contract normally for five years with possibility of renewal (secondment welcomed if possible) Unfurnished accommodation provided at rent (excluding rates) up to 7½ per cent of salary

Applications (ten copies), detailing qualifications and experience, and naming three referees by December 20, 1963, to Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained

---

UNIVERSITY OF KHARTOUM

FACULTY OF SCIENCE

Applications are invited for (i) Professor and (ii) Senior Lecturer or Lecturer in Botany Salary scales Professor, £S 2,760 per annum , Senior Lecturer, £S 2,052 by £S 75 to £S 2,277 per annum , Lecturer, £S 1,227 by £S 75 to £S 2,052 per annum Entry point according to qualifications and experience Cost of living allowance approximately £S 180 per annum, at present Outfit allowance £S 50 Family allowances Wife, £S 60 per annum , first child, £S 90 per annum , second and third child, £S 30 per annum, each (£S 1 = £1 0s 6d sterling) Passages for appointee and family on appointment, termination and annual leave There is a superannuation scheme and arrangements can be made to maintain F S S U policies Direct appointment on contract normally for five years with possibility of renewal (secondment welcomed if possible) Unfurnished accommodation provided at rent (excluding rates) up to 7½ per cent of salary

Applications (ten copies), detailing qualifications and experience, and naming three referees by December 20, 1963, to Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained

---

UNIVERSITY OF EDINBURGH

DEPARTMENT OF VETERINARY PHYSIOLOGY

Applications are invited for the post of Electronic Specialist to establish and take charge of an electronic workshop from January 1, 1964 Preference will be given to candidates holding Higher National Certificates The duties will include the construction, modification, and maintenance of high quality electronic apparatus used in biological research Knowledge and experience of both valve and transistor methods will be required Salary in the range £765 to £900 per annum, with placement according to qualifications and experience

Applications, stating age, qualifications and experience, should be sent to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, as soon as possible

BTL

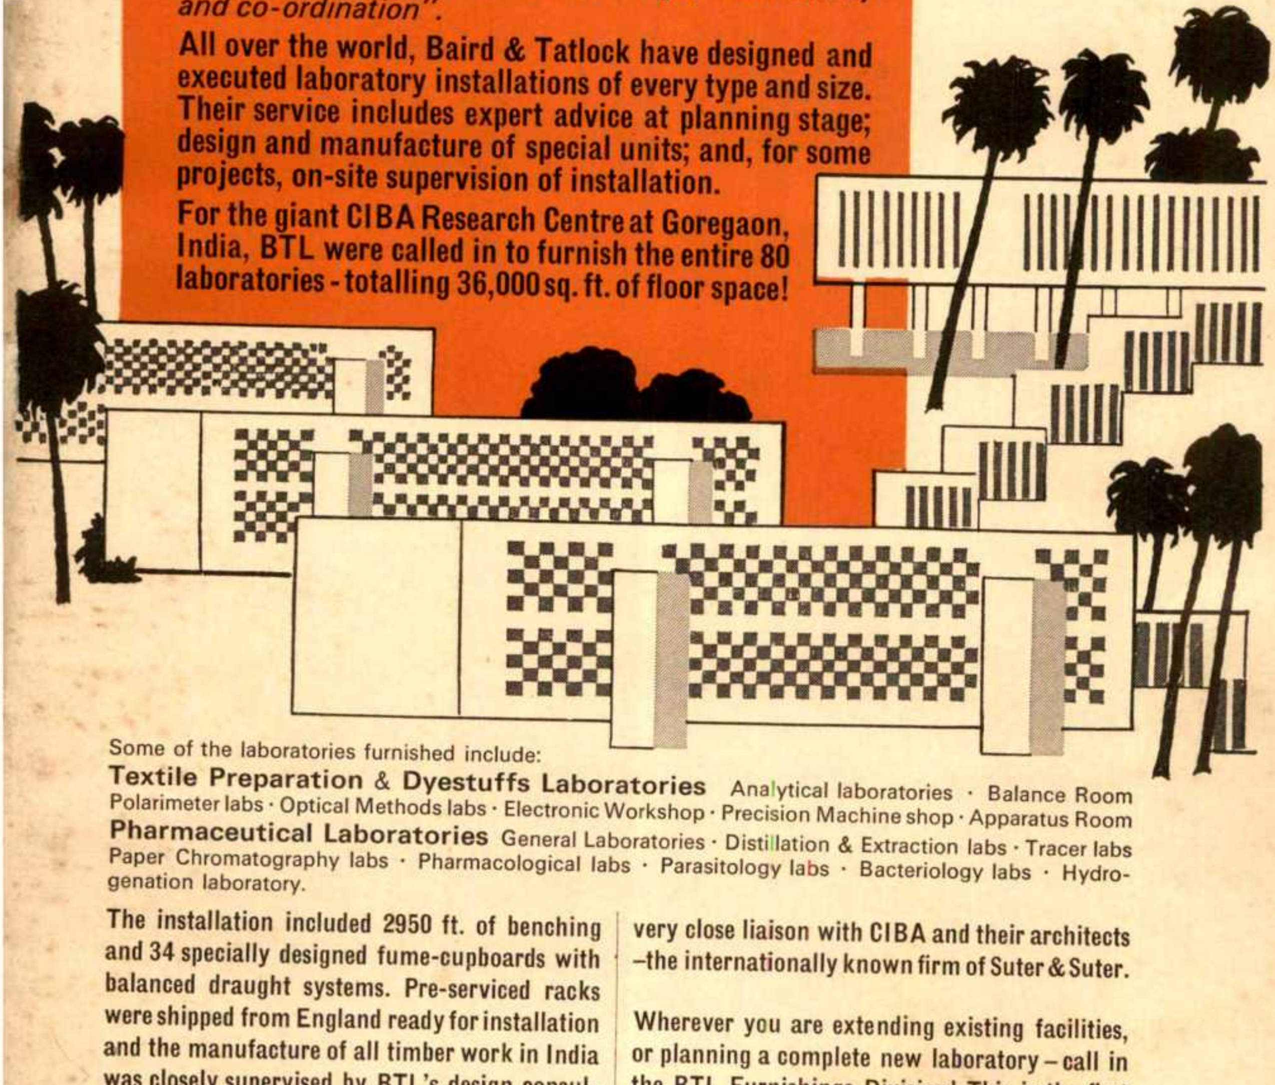
भारतमें सीबाका अनुसन्धान केन्द्र

COMPLETELY FURNISH THE LABORATORIES OF SOUTH ASIA'S LARGEST RESEARCH CENTRE!

"A remarkable achievement in design, consultancy and co-ordination".

All over the world, Baird & Tatlock have designed and executed laboratory installations of every type and size. Their service includes expert advice at planning stage; design and manufacture of special units; and, for some projects, on-site supervision of installation.

For the giant CIBA Research Centre at Goregaon, India, BTL were called in to furnish the entire 80 laboratories - totalling 36,000 sq. ft. of floor space!



Some of the laboratories furnished include:

Textile Preparation & Dyestuffs Laboratories Analytical laboratories · Balance Room Polarimeter labs · Optical Methods labs · Electronic Workshop · Precision Machine shop · Apparatus Room **Pharmaceutical Laboratories** General Laboratories · Distillation & Extraction labs · Tracer labs Paper Chromatography labs · Pharmacological labs · Parasitology labs · Bacteriology labs · Hydrogenation laboratory.

The installation included 2950 ft. of benching and 34 specially designed fume-cupboards with balanced draught systems. Pre-serviced racks were shipped from England ready for installation and the manufacture of all timber work in India was closely supervised by BTL's design consultants, who, at all stages of the project worked in very close liaison with CIBA and their architects —the internationally known firm of Suter & Suter.

Wherever you are extending existing facilities, or planning a complete new laboratory – call in the BTL Furnishings Division! This is the first step towards the speedy and successful completion of your laboratory project.

Gallenkamp JUNIOR

GAS CHROMATOGRAPH

- Ideal for educational purposes.
- Suitable for routine analyses.
- Simple controls—battery operation.
- For use with galvanometer or recorder.
- Open layout—full view window.
- For liquids with boiling points up to 80°C.

FOR INVESTIGATING

- **Retention times and volumes for individual organic solvents.**
- **Effects of varying the katharometer bridge current.**
- **Effects of varying the carrier gas flow rate.**
- **Effects of varying column length.**
- **Simple solvent and vapour mixtures.**
- **Comparison between peak height and peak area methods.**
- **Effects of change composition of the column packing.**

Price (without galvanometer or recorder) £45

The 'Gallenkamp' Junior Gas Chromatograph is intended for use in universities and technical colleges where the teaching of basic concepts of gas chromatography is an important introduction to the subject. It may be used both for demonstrations or individual experiments and enables the student to carry out analyses of unknown mixtures and to investigate the effects of varying the operation parameters. By careful design, the response is practically linear, undesirable characteristics such as tailing of peaks and zero drift have been minimised, and the apparatus is thus also suitable for simple applications in fields other than teaching.

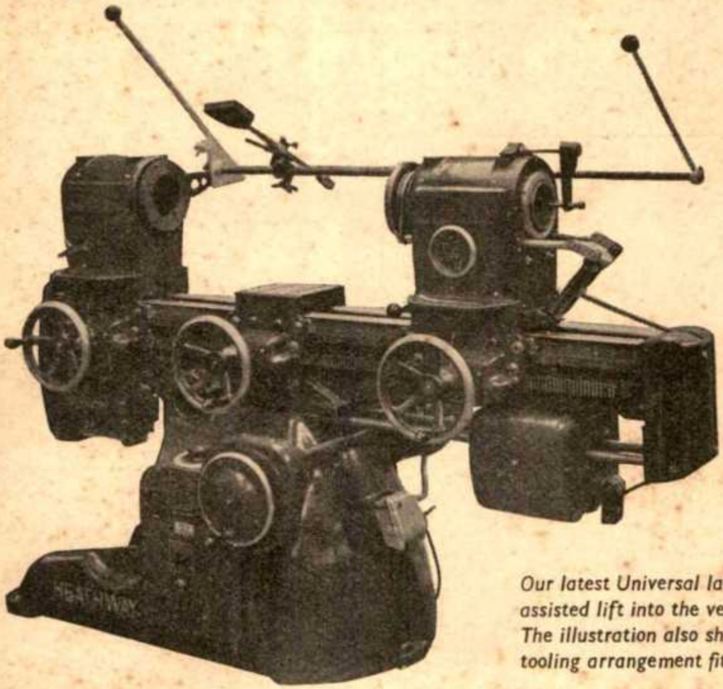
HEATHWAY

for Glass Working Lathes



Our latest Universal lathe with power-assisted lift into the vertical position. The illustration also shows our carbon paddle tooling arrangement fitted to the lathe.

All the HEATHWAY range of lathes have the following features :

- ★ **Robust construction and lasting accuracy**
- ★ **Efficient variable speed and easily accessible controls**
- ★ **Smooth traverses essential to good glassworking**

May we send you details of our range of lathes and equipment.

Write or phone :

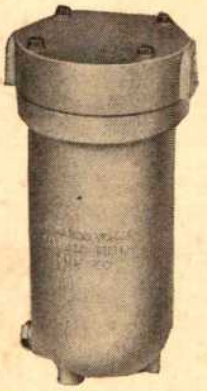
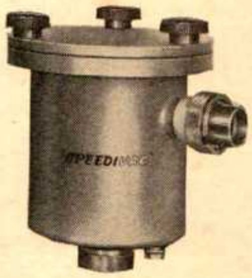
For an even longer, quieter life
from your "Speedivac" vacuum pumps–

NEW "SPEEDIVAC" FILTER RANGE



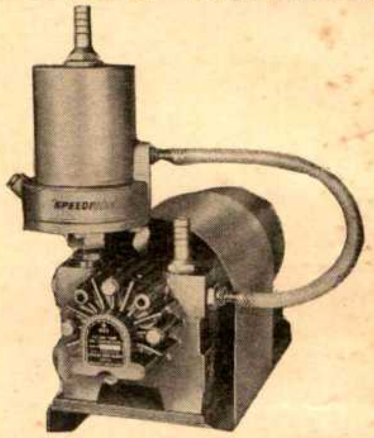
OIL MIST FILTERS

For trapping oil mist from the exhaust of oil-sealed rotary pumps. Cleaner air, quieter running, minimum maintenance, oil economy.



INLET DUST FILTERS

Stop dust down to 15 microns. Pump life increased. Adaptable to wide range of rotary pumps. Easily cleaned.



OIL RECIRCULATING FILTERS

Separate oil mist from the pumped gases on clean systems, and return to pump. Exhaust noise reduced. Continuous running possible. Pump life prolonged.

ICN MIMICS EFFECTS OF THYROXINE ON ISOLATED LIVER MITOCHONDRIA

Cyanogen Iodide (ICN) has been found to mimic in most respects Thyroxine's effects on isolated liver mitochondria (1). It is stable in water and serves as a donor of I^{+}.

ICN behaves like Thyroxine in these respects:

1. A quantity as small as 10^{-6}M produces substantial water uptake and swelling in rat liver mitochondria. As with Thyroxine, ICN-produced swelling is inhibited by serum albumin and strong sucrose (0.75M).

2. Antimycin A, Amytal and Cyanide also inhibit ICN-produced swelling. Thyroxine has been reported to display similar properties. (2,3).

3. EDTA is effective against ICN-produced swelling. It is also effective against thyroxine (4).

4. ATP causes rapid shrinking of ICN-swollen mitochondria. It behaves exactly the same with Thyroxine-caused swelling. (5).

UNIQUE HYPOGLYCEMIC AGENT FOUND FOUR TIMES AS POTENT AS TOLBUTAMIDE

4 Dimethyl Amino-N-Methyl 2, 2 Diphenyl Valeramide HCl was recently reported to be four times as potent as tolbutamide in lowering blood sugars.

It appears to act through a different mechanism than hypoglycemic agents which increase the oxidation of glucose.

Dulin, et. al. conclude that 4 D.M.D.V. appears to act by inhibiting liver glucose output—not by glucose oxidation or inhibition of metabolic effect of adrenal hormones. (1)

10-gram bottle, $4.50 gm. 5-gram bottle, $4.90 gm.
1-gram bottle, $5.50 gm.

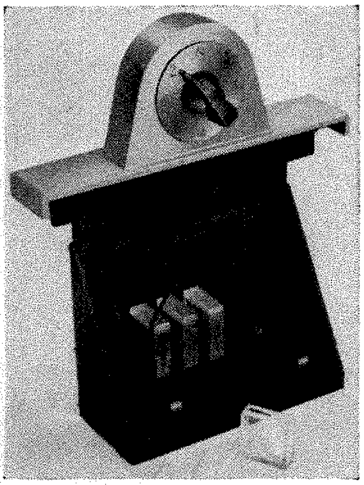
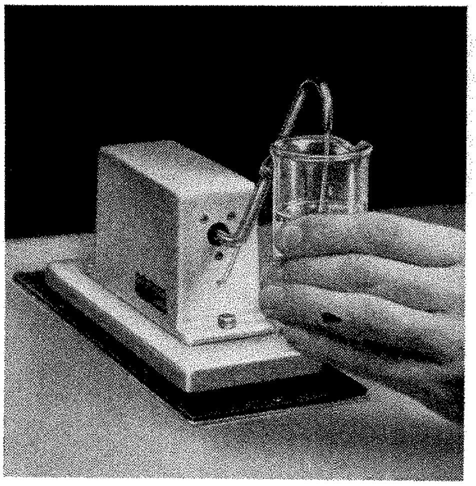
UNICAM

SP.600 with AUTOCELL

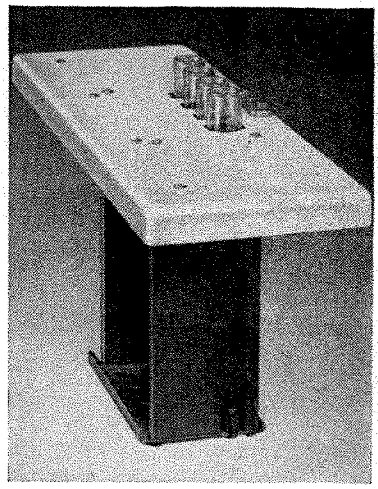
MICROCELL ACCESSORY AND TEST TUBE HOLDER



SP.680 MICROCELL ACCESSORY



SP.625 AUTOCELL



SP.630 TEST TUBE ACCESSORY

The Unicam SP.600 Visible Spectrophotometer is now available with the SP.625 Autocell Accessory; a unit which greatly reduces sample handling time. Also available is the SP.649 Power Supply Unit. This replaces the dry batteries normally supplied and provides an all-mains operation.

These latest developments, together with the SP.680 Microcell Accessory and the SP.630 Test Tube Holder, make the SP.600 Spectrophotometer the most versatile instrument for all absorption measurements in the region 360-1000 mμ.

The Autocell, Microcell and Test Tube Accessories are easily interchangeable and each is designed to fit into the cell well of the main instrument—no special fitting arrangements are necessary.

SP.625 Autocell

The new Unicam Autocell provides a completely automatic means of filling and emptying the special sample cell. One control is provided (see illustration above) and the operator can fill and empty the sample cell without any risk of cell breakage, sample spillage or contamination. This speeds analysis and greatly improves accuracy and reliability. The minimum sample volume required is 5 ml. Tests have shown that less than 1 per cent of sample volume remains after emptying. The sample comes into contact only with fine bore polythene or stainless steel tubing.

SP.649 Power Supply Unit

The Power Supply Unit has been designed to replace both H.T. dry batteries and can be easily fitted to every SP.600. It will appeal to those who require the extra convenience and reliability of an all-mains operated instrument. The unit consumes less than 5 watts and its output is unaffected by mains voltage fluctuations of ±12½ per cent.

Full information on the SP.600 and its accessories will gladly be sent on request.

A BLUEPRINT FOR HIGHER EDUCATION

THE Report of the Committee on Higher Education, appointed with Lord Robbins as chairman in February 1961, is both a major educational document in itself and also something of a social landmark*. The terms of reference of the Committee were to review the pattern of full-time higher education in Great Britain and, in the light of national needs and resources, to advise on what principles the long-term development of higher education should be based, including whether any changes in that pattern or any new types of institution were desirable, and whether any modifications should be made in the present arrangements for planning and co-ordinating the development of the various types of institution. It brings to an end a period of uncertainty and delay, removing the last excuses for procrastination and setting the full weight of searching enquiry behind its recommendation that Britain should and can plan to admit 17 per cent of the age-group to higher education in place of the present 15 per cent, of whom some 8.5 per cent are full-time. It disposes authoritatively of the idea of there being any risk within the next twenty years that the growth in the proportion of young people with qualifications and aptitudes suitable for entry to higher education will be restrained by a shortage of potential ability. Fears that expansion will lead to a lowering of the average ability of students in higher education have proved unfounded.

Nor is this inconsistent with the view widely entertained that there are already, in any event, some students at the universities ill-qualified by aptitude or character to profit by a university education. This may be due in part to the differentiation between institutions which the Robbins Committee deplores: distinctions based on adventitious grounds, whether historical or social, are, it observes, wholly alien to the spirit that should pervade higher education. The Committee wishes to see the removal of any designations or limitations that cause differentiation between institutions performing similar functions, while fully recognizing the need for a variety of institutions with differing functions. Student wastage and incompatibility can, however, equally be due to imperfections in the selection process, and it should be noted that the Committee specifically recommends research by an independent body into the extent to which aptitude tests might supplement other features of the selection process.

The Committee's proposals for the expansion of higher education from 216,000 full-time places in 1962–63 to about 390,000 in 1973–74 and some 560,000 (on present estimates) in 1980–81, of whom 350,000 will be in university institutions, are not based on narrow calculations of the demand for manpower. They are based on the conviction that there is a broad connexion between the size of the stock of trained manpower in a community and its level of productivity per head. In modern societies the skills and versatilities required are increasingly those conferred by higher education, but while the Report takes it as axiomatic that courses of higher education should be available for all those who are qualified by ability and attainment to pursue them and who wish to do so, it lends no support to the idea of a 'right' to higher education. It points out unequivocally that all those engaged in higher education, both teachers and taught, are privileged persons and the freedom they enjoy carries great responsibility. Public opinion will not support the cost of higher education unless teachers are actuated by a high sense of professional obligation and students are actuated by a corresponding sense of the obligation to work.

In advocating a programme of expansion which is estimated to cost £742 million in 1980–81 in place of £206 million in 1962–63, that was wisely and timely put. No less cognate, however, is the insistence of the Committee that higher education not only requires expansion but it also requires a system—a feature that has hitherto been lacking. To secure the smooth functioning of the proposed system, however, the Report also proposes some changes in the administrative arrangements, including ministerial responsibility. It is on this last point that there is one dissentient from the measures proposed to secure the necessary co-ordination: Mr. H. C. Shearman, who would have a single Minister for Education rather than a Minister of Arts and Science, responsible for the University Grants Committee, the Research Councils and like institutions, with other institutions of higher education under the Minister of Education or, in Scotland, the Secretary of State, as proposed by his colleagues.

These and the rest of the Committee's 178 recommendations, however, should be considered first in the light of the aims of higher education set forth alongside the principles which guided the Committee in framing its recommendations as well as conducting its enquiries, which are set forth in the second chapter of the Report. First, then, while assuming that needs of the present and still more of the future demand that there should be a system of higher education, replacing the largely uncoordinated activities and initiative of the past, the Robbins Committee does not suggest that all the activities concerned should be planned and controlled. It attaches great value to the freedom of individuals and institutions in any academic system, and the chapter on academic freedom and its scope is forthright and unequivocal: the principle of the University Grants Committee is not merely endorsed, but regarded as an essential ingredient in any administrative structure for higher education. The Committee considers that central decisions should be coherent and take account of the interests of all sectors of higher education, and that decentralized initiative should be inspired by common principles.

Next, in any properly balanced system at least four essential objectives are visualized. Instruction in skills suitable to play a part in the general division of labour is put first, because this vocational aspect is sometimes ignored or undervalued, and Britain's progress depends to a much greater extent on skills demanding special training. With this the Robbins Committee postulates that what is taught should be so taught as to promote the general powers of the mind. The aim should be to produce not more specialists, but cultivated men and women. Nor can higher education be dissociated from the advancement of learning. The search for truth is an essential function of institutions of higher education, and the process of education, the Committee adds, is itself most vital when it partakes of the nature of discovery.

---

* *Committee on Higher Education. Higher Education.* Report of the Committee appointed by the Prime Minister under the Chairmanship of Lord Robbins. Pp. xvi+335. (Cmnd. 2154.) (London: H.M.S.O., 1963.) 15s. net.

Elsewhere in the Report, the Committee discusses some of the controversial issues concerning the balance between teaching and research and the distribution of research between the institutions of higher education and other bodies. The answers given to those questions have a close bearing on the actual structure of Government organization and Ministerial responsibility. Fourth among its aims, however, the Committee places the transmission of a common culture and of common standards of citizenship. It believes that it is a proper function of higher education to provide in partnership with the family that background of culture and social habit on which a healthy society depends.

Coming now to the guiding principles of the Report, that of availability of courses to all who are qualified and wish to pursue them has already been noted. Next, the Committee places the principle of equal academic awards for equal performance, rejecting the retention of formal differences in terminology that do not reflect real differences in attainment. On the status of institutions, it insists that distinction should be based on difference in functions and in emphasis or acknowledged excellence: there should be no freezing of institutions into established hierarchies, but excellence should be recognized and encouraged wherever it exists and whenever it appears. Great importance is attached to opportunities for the transfer of a student from one institution to another when appropriate, and the organization of higher education must allow opportunity for free development of institutions, for experiment, for the safeguarding of standards and the production of as much high excellence as possible.

While the Robbins Committee was concerned primarily with the long-term development of higher education, it recognized that during the years 1965–68 Britain would be faced with an emergency arising out of the very large numbers of boys and girls born just after the Second World War who will then reach the age of higher education. If this situation is not met adequately the long-term plans may well be frustrated. The present plans for the universities are designed to allow for 150,000 places by 1966–67 and 170,000 in 1973–74. For the colleges of advanced technology, 15,000 places are planned in 1966–67, rising to 21,000 by a date depending on capital investment after 1963–64, and for training colleges in England and Wales authorized plans allow for 80,000 students in general and specialist colleges in 1970–71. It is now apparent that in 1966–67 there will be a shortage of 19,000 places in universities and 25,000 in 1967–68; for higher education as a whole the total shortage is estimated as 20,000 and 25,000, respectively.

To meet this shortage, the Robbins Committee considers that the present target figure of 168,000 places for the universities, including the colleges of advanced technology, in 1966–67 must be increased by some 10 per cent. It recommends to this end a substantial increase in the existing capital building programmes of the universities for 1964 and succeeding years. More accommodation, for teaching and especially for residence, is a prime essential, and the Committee insists on the need for firm assurances to the universities that sufficient funds will be available forthwith both to meet the short-term problem and for the long-term developments which the Committee recommends, if confidence in the Government is to be restored. It recognizes, too, that there will be difficulty in finding sufficient qualified teachers to meet all the needs of the emergency period, and whatever means of improvisation are adopted, including the provision of more technical and secretarial assistance, the extra burden on teachers is likely to be considerable.

It is all the more important, accordingly, that it should be clearly understood that any inroads on present standards are transitory and will be redressed as soon as possible and that adequate recurrent grants are available for all the necessary measures. It is not the least merit of the Robbins Committee that it faces the full implications of its proposals generally or that it leaves no doubt as to the deplorable effect of Government vacillation and changes in university policy in the past. Further, while it does not go into details of possible methods of improvisation for this emergency period, it does point out that some of the changes in organization recommended as part of its long-term proposals could assist in meeting the immediate need. This is a further and weighty reason for an early decision on some of the Committee's recommendations in regard to administration and also on the importance of speedy action on some of the less controversial measures proposed.

Further thought may well be desirable as to whether a Minister of Arts and Science should be appointed as co-ordinating Minister rather than one of the other alternatives. However, there would seem to be no reason why inter-ministerial and inter-departmental consultations to concert measures to meet the crisis should not be put in hand forthwith, or the Ministries concerned, the University Grants Committee, the Committee of Vice-Chancellors and Principals and representatives of other relevant associations brought together for appropriate consultation on the proposals of the Report. Nor does there seem to be any *prima facie* reason for delay in establishing and bringing into action the Consultative Council, consisting of representatives of educational and other interests, the creation of which is recommended by the Committee to consider major questions covering the whole field of higher education as well as its relations with the schools. The Statement issued from 10 Downing Street, on October 24, indicates indeed that the Government appreciates the urgency of the situation, but it gives no hint of an early decision on changes in organization, although these will not be allowed to delay the work on expansion which is now being carried out.

The hard core of the Committee's proposals for long-term expansion of higher education is to be found in the chapter entitled "The Future Pattern of Higher Education". It is visualized that by 1980–81 some 346,000 places will be provided in universities when some 60 per cent of students enter full-time higher education and go to a university instead of the present 55 per cent. This will involve expansion of many of the multi-faculty universities to accommodate 8,000–10,000 students, but even so there will be a need for some 50,000 places over and above what could be provided from existing institutions. A further 30,000 places will be provided by the foundation of six new universities in addition to those now in formation, one or perhaps two of which would be in Scotland and one a Special Institution for Scientific and Technological Education and Research, development of which the Committee recommends as a matter of special urgency. The remaining 20,000 places could be met by giving university status to some of the regional colleges, central institutions and colleges of technology

The colleges of advanced technology, which elsewhere in the Report it is recommended should become technological universities with full university status, are included in the calculation of the expansion of existing universities, and it should be noted that, besides the special institution already mentioned, the Committee recommends development of a similar institution from a selected college of advanced technology Institutions like the Imperial College of Science and Technology, the Manchester College of Science and Technology and the new University of Strathclyde, will have strong postgraduate elements, and together these five technological institutions should fill a gap that has been most noticeable in Britain and facilitate the major effort to expand technological research which is also recommended in the Report As regards the colleges of education, while the Committee proposes that the numbers entering some colleges in England and Wales should rise to 40,000 by 1974, it does not propose a rise in entry after that date the colleges will then be supplying 111,000 students, rising to 131,000 in the middle and later years of the decade For colleges of education in Scotland the Committee proposes expansion to 15,000 students by 1980–81, and the numbers of places in colleges of further education is assumed to rise from its present 31,000 to some 65,000

The question of places is, of course, only one aspect, and the Robbins Committee then considers the location of universities, the areas of study, professional education and the education of adults generally It urges the claims of the large cities and centres of population in determining the location of the new universities, and envisages that the present 51 per cent of students taking science and technology will increase further, though it would view with some concern any continuing reduction in the proportion of students taking arts subjects A growing proportion of such students has been taking social studies, and any decline or weakening in the study of the humanities would impoverish Britain's intellectual and spiritual life The implications of a more intimate contact between professional bodies and institutions of higher education are perhaps passed over too lightly, probably because the Committee's terms of reference relate to full-time higher education However, it is fully aware of the importance of the activities of the extra-mural departments of the universities, of the Workers' Education Association and local education authorities in adult education and that it is desirable that the universities should co-operate in developments opened up by the television services and other media of communication

Of vital importance in expansion is the quality of the staff, and the Report examines in some detail the problems which staffing the new and expanded institutions will present It deprecates any attempt to draw a sharp line between university teachers and the teachers in other institutions of higher education while research is a primary function of universities, this does not mean that it is only in universities that fresh work is needed and original work is done On the contrary, both in further education and the colleges of education, the Committee expects the student/staff ratio to recognize that teachers need time for reflexion and personal study Moreover, the Robbins Committee is concerned about the deterioration in the qualifications of graduates teaching in the upper forms of schools This itself can affect higher education adversely, but the deterioration can only be halted if the proportion of good honours graduates who become school teachers is, in the long term, higher than at present

Nevertheless, while the Committee anticipates in higher education in the immediate future a serious aggravation of the strains and stresses of the past two decades, it does not consider that the expansion of higher education of itself need cause a deterioration in the staffing of schools It emphasizes rather that higher education itself can only attract recruits of the necessary quality if it offers appropriate conditions of service and economic inducements In this connexion the Committee directs attention to the importance of adequate prospects of promotion, recommending a review of the structure of university staffing as a whole, and of freer movement of staff between higher education, Government and other research establishments and industry, and to the serious danger of a shortage of technicians, if not of secretarial assistance On teaching and research, pertinent observations are made in the Report Apart from recommending a major effort to encourage an increase in technological as well as scientific research (including an increase from 20 to 30 per cent by 1980 of the proportion of graduates proceeding to postgraduate work) and closer links between university institutions and Government research establishments and industry, it considers that in making appointments and in promotions, the diversity of gifts is not sufficiently honoured and published work counts far too much in comparison with other kinds of excellence The Committee recommends specifically the abolition of distinctions in salary scale between reader and senior lecturer and that in promotions to the latter grade particular attention should be paid to distinction as a teacher The full weight of the Committee's authority is put behind further attention to teaching methods and to curriculum research and development in the schools as well as in institutions of higher education The need for further educational research in the universities and into the many aspects of higher education is clearly recognized without any specific comment on the proposal for an educational research council

It will be clear that in recommending that the colleges of advanced technology should in general be designated as technological universities, with power to award both first and higher degrees, and that responsibility for their finance should be transferred to the University Grants Committee, the Robbins Committee concedes most of their claims and what was generally recognized as reasonable by most people Friction is more likely over the proposal to rename the teachers' training colleges of education, more particularly in their relations with the university departments, and there are numerous points of administrative detail to be determined even when the formal organization recommended by the Committee has been established This in itself, as already indicated, is a matter of some complexity on which the Committee was divided and will be discussed more fully later in the light of the recommendations of the Trend Committee It should suffice here to indicate the broad outline of the arrangements proposed up to the level of a Minister for Arts and Science, to whom the University Grants Committee and the Research Councils should be responsible

It is visualized that governing bodies for autonomous institutes, which normally contain a majority of lay members, and for institutions of higher learning, which are administered by local authorities, should be properly constituted with suitable academic representation and lay membership According to the Report, the Committee of Vice-Chancellors and Principals should be reconstituted, each university being represented on the Committee by its chief administrator and by a member of the academic staff elected by the senate and this Committee should appoint a standing committee of 15–20 members, and standing or *ad hoc* committees as required Likewise, the University Grants Committee should be responsible for advising the Government on the needs of all autonomous institutions of higher learning in Great Britain and for distributing grants and should set up standing committees to deal with areas of interest and *ad hoc* committees to deal with current topics The present practice in regard to accountability should be maintained, but improvements are needed in the present system for allocating recurrent grants, and an independent body should be set up to advise the Government on salaries of academic staff in autonomous institutions of higher learning

Leaving this matter of ministerial responsibility and that of administration generally with the observation that the Robbins Committee is as aware of the importance of reducing the burden on Vice-Chancellors as it is of that of associating non-professional staff with internal self-government and particularly of keeping staff at all levels informed of the reasons for policy decisions, there are two related matters which call for note Like Sir Burke Trend and his colleagues* the Robbins Committee is concerned that the finance of universities and university research should come from more than one public source and this is one of the main reasons why it recommends an upward revision of university fees so that they provide at least 20 per cent of current expenditure in place of the present 11 per cent. The effect on public expenditure would be mainly a change in the channels of distribution, but there would be another important consequence the subsidy to overseas students could be handled on more rational lines

Unlike Sir Burke Trend and his colleagues, the Robbins Committee shows itself well aware of the vital importance of the situation overseas and its bearing on Britain's future It found no firm basis for estimating the future demand for places for overseas students but was convinced that even in the short-term emergency Britain must continue to find places for such students The Committee's long-term forecast assumes that the present proportion of places will continue with an increase in numbers from about 20,000 in 1962–63 to about 50,000 in 1980–81 It is pointed out, however, that with fees at their present level and under present conditions this represents a substantial subsidy over which the nation has no control and for which it receives no credit By calculating the fees for overseas students on a uniform basis which does not vary from one institution to another, but is no higher than for other students and creating at the same time, as part of Britain's contribution to educational assistance overseas, a fund for helping any students requiring such assistance, a more rational procedure would be established and one which would also make clear the full magnitude of the British contribution

While the Government accepts that changes in organization will be necessary and has undertaken to make a full review of higher education and student finance in the light of the considerations put forward in the Report, its attitude on this and many other particular points is not defined in the Statement which has already been issued That Statement indicates that the Government has accepted the basic assumption of the Report that courses of higher education should be available for all those who are qualified and wish to pursue them and that it has adopted the Committee's calculations for 1967–68 and 1973–74 as its objective Recurrent and capital grants for university institutions concerned are being adjusted to this new objective of 197,000 full-time students in university institutions in 1967–68 and 328,000 in all higher education, the University Grants Committee and the education departments are being asked to discuss the best methods for securing this expansion This expansion, moreover, is to be the first step in formulating a ten-year programme to give 390,000 places in full-time higher education by 1973–74, 217,000 will be in institutions of university status The preliminary action to confer university status on the colleges of advanced technology and certain Scottish institutions is also being taken, the University Grants Committee is being asked for early reports on the location of a new university in Scotland and on the further development of the special institutions for scientific and technological education and research recommended in the Report This all adds up to a programme with which considerable and valuable progress could be made while clear decisions are being reached on difficult problems of organization None the less, the value of such work and the sincerity of the Government's intentions will only be attested by the swiftness with which those decisions are reached and the firmness with which its financial and other support is maintained independent of fluctuating circumstances, whether economic or political

SEEKING AND SHAPING

By Sir ROBERT WATSON-WATT, C.B, F.R.S

THE distinguished author of the remarkable and important volume, *Forschen und Gestalten Reden und Aufsatze, 1930–1962**, is almost as well known in London as in Dusseldorf, Bonn and Berlin As Staats Sekretar of Land Nordrhein Westfalen, he has been responsible for a major portion of the renaissance of the most concentrated and most important industrial area in Germany, the land between the Rhine and the Ruhr In another field, in which I first met him in the mid-'twenties, he was an energetic pioneer of 'the electronic age' In this field, too, he has led, in co-operation with the late General Wolfgang Martini, the vigorous Ausschuss fur Funkortung (now the Deutsche Gesellschaft fur Ortung und Navigation, E V), in international conferences on radio-aids to travel by air, sea and land

Brandt's weighty volume earns the adjective 'formidable' in the abstract and the concrete alike Its two-thirds of a thousand pages and some three-pounds weight are autobiographic in a very special sense, which may fairly be described as 'autobiography by exhibited sample' It presents the text of discourses bearing on his major activities from 1930, when he was president of the German Republican Students' Union, to January 1962, when he presided over the Section of Culture and Science in the Assembly of the Atlantic Community in Paris. It is thus, by implication, a sampling review and self-analysis of his personal contributions to the technological progress, in peace and in war, of his native land. The range of specialized activities represented in this collection of writings and addresses is covered in four sections, dealing respectively with radio and radar techniques (120 pp., 1953–62), transport policy and techniques (273 pp., 1949–59), rationalization (63 pp., 1952–56), research and science (175 pp., 1953–62).

---

* *Forschen und Gestalten Reden und Aufsätze, 1930–1962* Von Leo Brandt Pp xii+669 (Koln und Opladen, Westdeutscher Verlag, 1962)

These main sections are supplemented by two fragments of technical history, each of 9 pp., from "The General Weekly of the Jews in Germany", 1960, by a postscript of 13 pp., and an index of more than 250 personal names appearing in the text.

Surviving workers from the 'twenties and 'thirties will, in turn, become nostalgically biographic as they read Leo Brandt's account, written in 1934, of his screened cage and its measuring equipment for investigation of radio-receiver performance. A much wider population of initiators, designers, producers, users and victims will find his summary of "German Radio Technique, 1934" absorbing, and (in widely different degrees) satisfying, surprising and/or illuminating.

As Entwicklungsgruppenleiter fur Funkmessgerate des Generalbevollmachtigen fur die technischen Nachrichtenmittel, and as Vorsitzender der Arbeitsgemeinschaft "Rotterdam"—this for the post-British introduction of centimetric wave-length equipment—he gives in 21 pp. a compact account of the technical effort in Germany which was directed mainly to 9-cm and 3-cm wave-lengths.

This review is followed by a brief account, dated 1949, of the development in the preceding 15 years of commercial radio receivers, by a 28-pp. retrospective review of German radar technique, a 34-pp. survey of the state of German centimetre-wave technique at the end of the Second World War and, appropriately, 13 pp. on the German station for radioastronomy and for basic research on radar. The whole of Section 1 of the book is essential, though necessarily inadequate, to this general history of centimetric radio in general and of radar in particular. It is to be hoped, in particular, that the papers of the late General Wolfgang Martini, general commanding the communication troops of the Luftwaffe, can be made available to the student of radio and radar devices in naval, military and air warfare.

Section 2, of this book on 'seeking' and 'doing', is devoted, in its 273 pp., to policy and techniques in the field of transport, beginning with a 1949 article on the reconstruction of the very important Rheinbahn, which serves the great and crowded industrial area between the Rhine and the Ruhr. Its principal city, Dusseldorf, is the focus of a population of six million or more, within a radius of some 30 miles. The articles in Section 2 are illustrated by copious photographs, graphs and tables which give a clear, compact and impressive account of the restoration and expansion of public transport facilities, with text and tables illuminating the requirements in material as well as the costing and financing of the system in Nordrhein-Westfalen.

While railway transport was the most urgent and demanding section of the whole, road transport was of no less importance in the total picture: indeed, the theoretical maximum carrying capacity of road transport was estimated at 16 per cent greater than that of rail—70 milliard ton-km against 60 in the year 1949. To these major services there must be added that of the inland waterways, and these are considered in a chapter dealing with the whole post-war problem of the nation's inland water-transport network up to 1950. The influence of the jet aircraft in international air transport, especially in Europe, is discussed in the last chapter of Section 2, based on a lecture in Genoa, in October 1959.

Section 3 deals with rationalization, in five discourses dating from 1952 to 1956, four of these having appeared in the records of the Working-group for Rationalization of the Land Nordrhein-Westfalen. They deal, in turn, with problems in rationalization, the influence of post-war occurrences on German productivity, the road to the exhibition "All Shall Live Better", Dusseldorf, 1953, rationalization as a state-political problem, 1953, the road to the Research Institute for Rationalization, 1956—dealing with the opening of the Research Institute for Rationalization at Rhine-Westfalen's Technische Hochschule, Aachen.

Section 4, "Research and Science", the second longest in the volume (175 pp.), comprises seven addresses and four articles dated between 1953 and 1962. The titles are, in all cases, self-explanatory: man and technology, the need for German research, atomic energy as an economic source of power for Germany; report on the renaissance of German aviation research (1955), the furtherance of science in the atomic age (1956), science in need (1957), research, the gate to the future (1958), the joint atomic energy research installation of the Land Nordrhein-Westfalen in Julich (1958), phases in the technical development of our time (1958); the group for atomic research in common with the Land Nordrhein Westfalen (1960), the strengthening of Atlantic Co-operation in the area of science (1962).

This catalogue of activities is in itself sufficient to reveal the astonishing range of the public interests to which Leo Brandt has devoted his gifts in research, technology, economics, political science, organization, management, public institutions, and in their application to the service of the State and the nation. But the supplements to the texts, tables, diagrams, maps, illustrations, and—perhaps most illuminating of all—the frontispiece showing the author at work, under the drive of a multitude of needs and the vision of a multitude of facilities, are the clearest pictures of the man who was successively dedicated to the advance, to the defence, to the renaissance and to the world-service now demanded of his country in the fields of Forschen und Gestalten, of "Seeking and Shaping". In serving his State and his country he is serving well the world at large.

Section 5 of the book contains two specially individual chapters, the first "On the Share of Jewish Personalities in the Development of the German Electrical Industry"; the second, "To the Memory of Leo Lowenstein". The former is, as every student of modern science knows, an impressive gallery of giants. Here are Heinrich Hertz, Albert Einstein, Max Born, James Frank, Lise Meitner, Georg Schlesinger. In the technological "Who was Who" are such pioneers as Emil Rathenau, Carl Furstenberg, Walter Rathenau, Felix Deutsch, Reinhold Rudenberg, Julius Laufer, Alfred Berliner, Paul Heinrich Perls, Rudolf Goldschmidt, Emil Mayer, Graf Arco, Otto Bohm, Erich Zepler, (Prof.) Korn, and so on.

One Leo Lowenstein has a special place in this list. Born in 1879, he studied chemistry in the Technische Hochschule in 1908, then in Gottingen and Berlin under the great Nernst. He became an assistant to Geheimrat Nernst, and was succeeded in that position by one Frederick Alexander Lindemann, later to be the first Baron Cherwell.

Lowenstein, as a reserve officer in a Bavarian telegraph battalion in October 1913, introduced sound-ranging as a military technique. In the relatively static phases of the First World War, his equipment became a remote precursor of radar, and when Lindemann and I came together at the Royal Aircraft Establishment, in 1915, Lindemann talked to me interestedly about sound-ranging. Lowenstein went on to achieve radio communications on 20-cm wave-lengths, using 3-m diameter parabolic antennæ, over a distance of 40 km. On August 12

1929, he was authorized to initiate experimental work on guided rockets. The lassitude which delayed many promising military inventions was overcome by the young Wernher von Braun, who was engaged by General Dornberger—although no one appears to have thought of telling him about Lowenstein's priority.

The Fates have their own sense of the amusing and the dramatic in their weaving of the webs of human destiny. The Lowenstein project, for guided rockets, the younger and later Wernher von Braun project, and the close association between Winston Churchill and Frederick A. Lindemann, brought the thoughts of two successive ex-assistants to Prof. Nernst in Berlin and also those of another brilliant ex-student from the Nernst 'stable', Henry T. Tizard, into the webs of initiative and of scepticism, and to the diverse weighing machines of optimism and pessimism on the fate of nations.

If I may be allowed a closing excursion beyond the ambit of the important papers of Leo Brandt, I would like to direct attention to the close association just mentioned. A treasured reward for the writing of *The Pulse of Radar* came in the form of a letter from a distinguished American lawyer who made history through a week-end tennis match. Having at his country home, not far from Banbury Cross, a guest named Winston Spencer Churchill he invited the University of Oxford tennis enthusiasts to send a team to play a week-end match against members of his house party. Thus did the frolicsome Fates bring Winston Churchill and 'The Prof', F. A. Lindemann, to their first meeting and their intimate friendship.

'PSYCHOGENETIC STRESS' AND AUTOINTOXICATION IN THE HONEY BEE

By ROY J. PENCE, ROBERT D. CHAMBERS and MANUEL S. VIRAY

Department of Entomology, University of California, Los Angeles

THE theory of the 'general-adaptation syndrome'[1] has engendered preliminary investigation to determine the effects of stress as it occurs in the honey bee, *Apis mellifera* Linn., on the assumption that social insects of the higher orders are more susceptible to symptoms of stress than insects of a more primitive nature. Results of these investigations have shown: (1) a similarity of physiological decline of a honey bee reacting to forced confinement, and a honey bee reacting to a stress created by externally applied chemicals; (2) the variance of activity of a honey bee abdomen, after it has been excised (disconnected from the co-ordinating centre), in comparison with that of an intact bee held in confinement; (3) the comparative reactivity of both systems, excised and intact, following exposure to chemically applied stress.

The fundamental question in this instance is: Why does a foraging honey bee returning to the hive laden with nectar or pollen succumb within a period of 1.5–2 h after capture and confinement, while an excised abdomen from an identical bee continues to remain active for as long as 48 h? On the surface it would appear that mortality of the intact bee could be attributed to over-exertion during its attempts to escape. However, it must be borne in mind that the honey bee is capable of many miles of tiring flight yet eventually succeeds in returning to the colony. The bee's 'objectivity', measured in habitat-maintaining behaviour or homing instinct, will usually prevail. Why then does the same insect surrender so quickly when denied the exercise of this instinct? It is felt that the limited period of tolerance to confinement is not the result of mere exhaustion. If energy expenditure alone is not accountable for the bee's 'resignation', leading to prostration and subsequent death, then there must be other factors instrumental in instigating this rapid decline.

It would appear that a syndrome is involved in association with stress—perhaps an autointoxicating, triggering mechanism which becomes involuntarily activated during the processes of stress[2]. When a foraging honey bee is confined to a glass jar placed near an open window, it makes hyperactive attempts to escape in the direction of natural light. If escape is denied the bee quickly dies. The time required for death is of primary interest, and it is on this period that attention is centred.

There obviously exists in the foraging honey bee some navigational instrumentation which ensures its return to the colony. Von Frisch[3,4] propounds the theory of internal clocks and the dependence of these mechanisms, in part, on the Sun. Considering the period of time that a honey bee can survive confinement, removed from all familiar objects of environment, it is found that this period is inversely related to the amount of natural light available to it[5]. Experiments also show that the bee's tolerance for confinement is much greater in the absence of natural light, and there is some indication that total darkness is less excitable than substituted artificial light. We are uncertain at this point what effect the various properties of light have on the related nervous and hormonal functions, and exactly how they are interrelated. Observing that a confined honey bee is more strongly attracted to ultra-violet than to natural light and, proportionately, the bee's period of endurance of confinement becomes significantly shorter, it appears that light in the ultra-violet spectrum is of importance[6,7].

In addition to light there are indications of other visual or sensory factors affecting the honey bee's behaviour and tolerance of confinement. The mere presence of small amounts of honeycomb exerts a striking placebo effect on a confined bee. Comb that has been coated to mask its characteristic odour, while retaining its original form, will also exert a placatory effect on an otherwise excitable honey bee. Activity is then lessened, with longer life resulting. There appears to be, however, a fairly specific amount of comb necessary to pacify a confined bee for a day or more. Comb which is coated to decrease the likelihood of chemoreception offers less pacification, while amounts smaller than the bee itself offer none. Light augments stress while a placebo decreases it. Blinding the bee, or placing it in a dark enclosure, will increase its tolerance to forced confinement. Elimination of the antennæ will, however, impose an opposite effect, for without these chemoreceptors the bee succumbs to confinement more readily. Behavioural studies of confined honey bees from which the antennæ have been severed have led to the belief that resignation occurs long before any factor of energy expenditure takes place. Subsequent examinations of respiration have substantially contributed toward this theory[8].

The area within which a foraging honey bee is confined has a definite relationship to its measure of endurance. A bee confined in a transparent enclosure of several square feet will succumb within an hour while, in a quart jar, life will be extended for from 1–2 h. Within an area of an inch or two, the bee remains seemingly co-ordinated from 1.5 to approximately 3 h; in a tightly fitted, transparent gelatin capsule for some 20 h. Freedom of motion

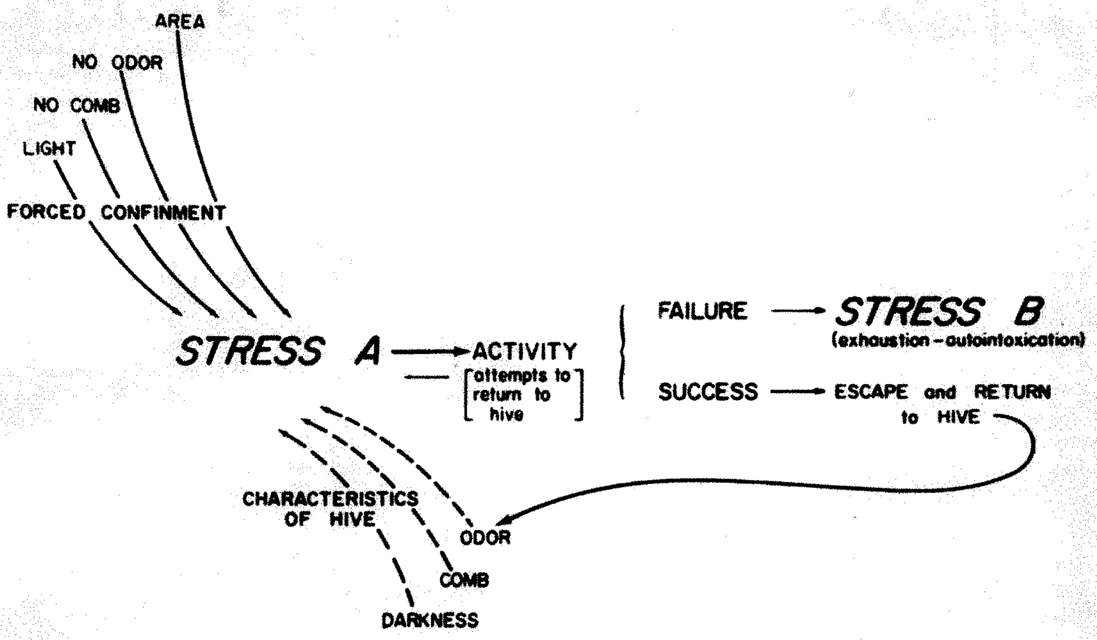

Fig. 1. Scheme of factors contributing to two 'types' of stress in the foraging honey bee
Forced confinement in natural light, in the absence of certain other environmental factors, suppresses exercise of habitat-maintaining behaviour. Continued suppression leads to beginning symptoms of stress *A*, manifested in hyperactive attempts to escape. Failure to regain natural balance results in stress *B*: death by exhaustion and autointoxication. Normality may be regained only if freedom is attained prior to debilitating effects of stress *A*

appears to be related to the bee's degree of 'frustration'. If a bee is given room to take wing toward its destination and then suddenly encounters an invisible barrier, its 'objectivity' is more abruptly thwarted. Conversely, constricted confinement will suppress or even eliminate objectivity.

Several factors of environment have an apparent effect on the highly organized, foraging honey bee in confinement. Light has been found to increase activity while the placebo effect of honeycomb reduces it. Honey bees in collective confinement have comparable objectivity, yet behave independently in their efforts to return to the colony.

Light and area affect activity which, when excessive, is deleterious and constitutes stress. Stress is the result of activity and energy expenditure and initiates activity. Thus stress, if not relieved, contributes to autotoxicity which, in turn, leads to mortality if no adaptation to the circumstances imposing stress is forthcoming.

The problem becomes one of defining the nature of a stress imposed on a foraging honey bee under confinement by separately examining similar symptoms of prostration primarily brought on by energy expenditure. To differentiate between the two, it was reasoned that first a stress would have to be induced by some externally applied chemical means. In this manner the energy expenditure resulting from chemical irritation could be compared with stress of a 'psychogenetic' nature induced by confinement alone.

The chemical selected for this investigation was menadione (vitamin K_3) which, though relatively non-toxic when applied topically at low concentrations and in minimal amounts, has an irritating effect which causes the bee to react with such violence that it eventually perishes due to exhaustion associated with chemically induced stress.

The results of an application of 0·001 ml. of 0·25 per cent menadione to the venter of a honey bee abdomen are comparable with stress symptoms of an untreated, confined bee. The time required for prostration is approximately the same, with both bees demonstrating comparable overall degrees of total activity. The important difference is that the untreated bee will be activated toward light in energetic attempts to escape, while the treated bee ignores light and expends comparable reflexive energy in attempting to rid itself of the chemical irritant.

Present evaluations clearly indicate that a topically applied irritant serves as a distracting agent which appears to supplant the original homing instinct. Thus, a stress induced by external sub-lethal chemical means becomes a substitute for a stress resulting from interference of the insect's natural behavioural pattern. This has been further substantiated through observations that irritated bees under confined conditions expend more energy yet live longer than those that are untreated. In other words, a confined bee more quickly falls prey to 'autogenetic stress' fostered through denial of its objectivity associated with the homing instinct. Measurements of losses in weight of both treated and untreated bees following death show losses to be greater in the treated than in the untreated bees; however, losses in weight alone only suggest energy expenditure.

The Warburg respirometric method of evaluation has proved particularly suitable for experiments in honey bee respiration. This technique enables one to evaluate respiration in terms of environmental, applied, and inherent factors which contribute either to decline or pacification of an isolated subject[8]. Considering the total oxygen consumption as the most reliable index of energy expenditure, it has now been confirmed that bees reacting to a chemically applied stress expend more energy yet live longer than untreated bees which react to confinement. Conversely, it has also been learned that untreated, excised abdomens expend more energy and live longer than treated abdomens.

Table 1. RELATION OF OXYGEN CONSUMPTION TO MORTALITY FOR: (1) INTACT HONEY BEES UNDER CONFINEMENT, IRRITATED AND NON-IRRITATED; (2) IRRITATED AND NON-IRRITATED SEVERED ABDOMEN*

Condition of bees	Oxygen consumption (μl.)	Period for 100% mortality (h)†
Severed abdomen irritated	52	36
Severed abdomen non-irritated	56	40
Intact bees irritated	144·5	10
Intact bees non-irritated	122·2	8

* Irritated with menadione 0·001 ml. of 0·25 per cent.
† Sixteen insects per test, three replicas of each test.

Respiration investigations have presented evidence that there exists in the foraging honey bee some potential of fatal autointoxication which becomes manifest when it is denied the exercise of normal habitat-maintaining behaviour. Results of these investigations have produced evidence that the period a bee can endure forced confinement is not based on expenditure of energy alone. The relationship of light to 'psychogenetic stress' has been evaluated by the simple expedience of altering light and its properties over bees confined within respirometric flasks. Quantitative analyses of the insects' threshold tolerances have thus been recorded, and take into consideration sensory mechanisms which moderate differences between normal and abnormal behaviour.

It is felt that more consideration might be given to insecticides which are known to trigger early stress symptoms, with subsequent autotoxicity, to promote the desired total lethal effect. One cannot help but question the part played by the insecticide *per se* when the important factor of 'physiological' stress remains undetermined. Therefore one is led to speculate on the possibility of using lower dosages of hazardous insecticides, with allowances for associated stress to contribute its role in mortality.

The still undetermined chemistry of toxic substances generated during the processes of stress should be considered[2]. It is suspected that these substances are released into the hæmolymph as evidenced by the dramatic effects this fluid has on normal tissue. When minute amounts of hæmolymph are transferred from the body of a 'stressed' honey bee on to the exposed organ of sting from a normal bee, a muscular hyperactivity occurs which is followed by abrupt and final cessation of any further movement. A freshly extracted, intact sting, when carefully removed and placed on a clean surface, continues to pulsate for some 20 min and becomes an excellent medium with which to test the pharmacodynamics of certain chemicals[9]. Body fluids removed from a 'stressed' bee 24 h after death are even more toxic. They will take immediate effect on an exposed sting and after injection into a healthy bee will cause death. It appears that a form of 'septicæmia' slowly materializes within the body of a bee which has succumbed to stress which is not detected in bees that have perished from other causes.

These preliminary observations have resulted in two new conclusions: (1) The honey bee, already recognized as a highly specialized insect, is still basically a creature of instinct. Apart from a limited number of reactions which give some evidence of adaptation, association, memory and learning, the bee responds in a fixed way to a given change in its environment[10]. We have known for some time that a factor of morale exists in the colony and we now have evidence that a honey bee is also subject to symptoms of 'neuroses' which become manifest in stress. (2) The processes of stress give rise to autotoxicity, which proves fatal to the bee, and the toxic substances, especially when aged and transferred to normal bees, are equally fatal.

FORMATION OF TRUE THREE-DIMENSIONAL CRYSTALS OF THE TOBACCO MOSAIC VIRUS PROTEIN

By R. MacLEOD, G. J. HILLS and Dr. ROY MARKHAM, F.R.S.

Agricultural Research Council, Virus Research Unit, Huntingdon Road, Cambridge

THE protein components of the tobacco mosaic virus and its relatives are rather remarkable substances. Although they can vary considerably in their amino-acid compositions, they can all assume a configuration that is ideally adapted to shield the sensitive and important ribonucleic acid part of the virus from its external environment, by forming a left-handed[1] tube having $16\frac{1}{3}$ peptide chains per turn[2] which not only encloses the nucleic acid thread as an inclusion compound but also fits it in such a way that there is a stoichiometric relationship between the primary phosphate groupings and the protein, presumably involving ionic compounds with the arginine guanidino groups[3]. The protein is also able to form this type of tube in the absence of the nucleic acid, either under natural conditions, when it is referred to as 'X' protein[4], or when the nucleic acid has been removed artificially by the use of dilute alkali or by acetic acid, when it is usually referred to as the 'A' protein[5,6]. However, in these last instances the restraints imposed by the inclusion of the nucleic acid thread are not present, and the protein molecules are then also able to form tubes composed of disks stacked

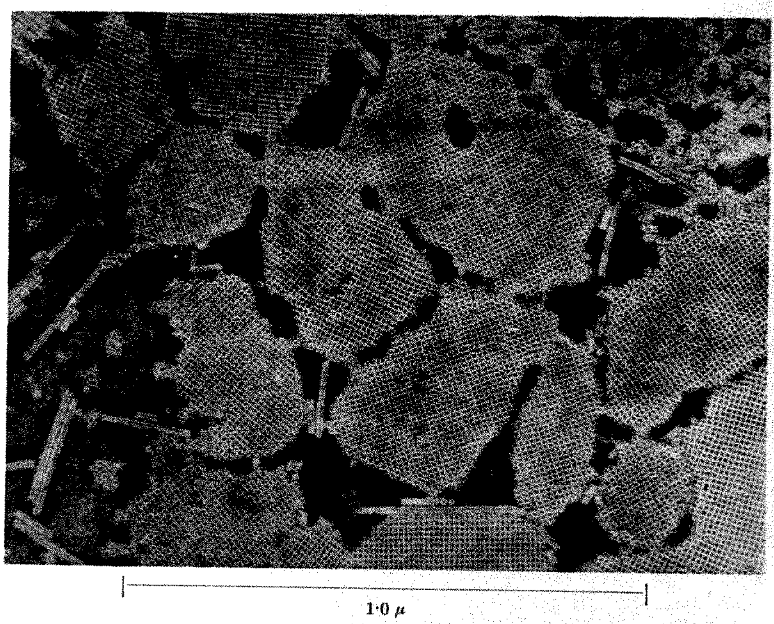

Fig. 1. Low-magnification electron micrograph of tobacco mosaic virus protein crystal. Note the angles on the crystal edges, the rods composed of stacked pairs of disks and individual flat disks

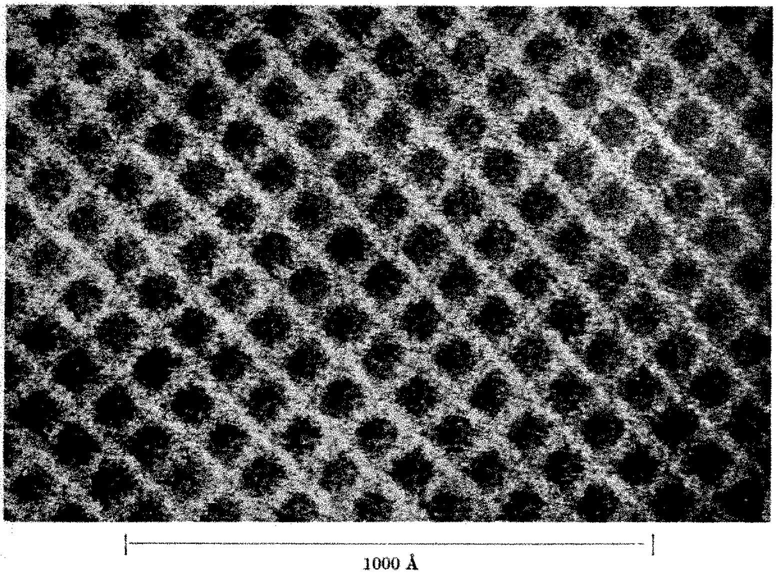

Fig. 2. High-magnification electron micrograph of the square mesh structure seen on the surface of the virus protein crystals

on each other in pairs and having 16 peptide chains per disk arranged radially[7]. This type of structure so closely resembles the helical tube that it is only quite recently that it has been recognized. However, its structure is readily noticed once one is aware of its existence, and we have noted that this type of tube is a not uncommon constituent of tobacco mosaic virus preparations.

Re-polymerized tobacco mosaic virus protein, whether in the form of a helix or a stack of disks, differs from the intact virus in that it has little tendency to form rods having a uniform length, and some rods may be as short as one pair of disks, which would appear to be the smallest stable structure of this type. Quite recently we have come across an entirely new way in which these disks can arrange themselves, namely, as true three-dimensional crystals. It seems not unlikely that when larger crystals of this type are grown, they may be used to determine the precise configuration of the peptide chains constituting the sub-units of the virus, using X-ray diffraction techniques, because such crystals should have advantages over the gels of virus that have been used so far.

The virus preparation used in this work was derived from the 'type' strain from Berkeley, California, and was adjusted to pH 10·3 with sodium hydroxide and left at 4° C for 24 h. The solution was then dialysed exhaustively against distilled water. On examination under the electron microscope, using potassium phosphotungstate as a negative stain[8,9], a number of flat plates were seen having a striking rectangular network rather like a mesh screen (Figs. 1 and 2). At first sight it was difficult to interpret these pictures because the size of the mesh was considerably smaller than the diameter of the virus rods, and the apparent width of the elements composing the mesh was not consistent with any of the dimensions with which we were familiar.

It transpired that these structures were artefacts of a new type. The appearance of negatively stained objects is very often so appealing to the eye that one tends to overlook the fact that the final image is not formed by those regions in the object where matter is present but, on the contrary, by those places where there is no matter to prevent the ingress of the negative stain, and that these are by no means complementary situations, particularly when one is examining a crystal lattice which may well have several planes in which the voids are distributed differently at different levels. In such cases any transparent, electron-transmitting, areas merely represent the projection on the plane of the image of those vertical regions where the stain is more or less excluded, and such a projection need not necessarily resemble in its major details the structures under examination, though, of course, there is a definite relationship between them.

This state of affairs is shown diagrammatically in Fig. 3. This figure shows the situation obtaining when transparent disks are arranged in a square lattice, with the interstices filled with an opaque stain. One then sees an array of four-cusped, squarish, stained regions arranged with the same spacing as are the disks, but displaced with respect to them. If a second layer of disks is then superimposed with their centres on the centres of the spaces between the disks in the first layer, two layers of cusped areas are superimposed out of step and the only regions not obscured by stain are the places where the disks in the two layers overlap. It will be seen that one then obtains an approximation to a square mesh with an edge period of $1/\sqrt{2}$ times the diameter of a single disk at 45° to the array of disks, which incidentally are now arranged in two successive layers of a body-centred tetragonal lattice as viewed normal to the (001) face. Further layers of disks can be

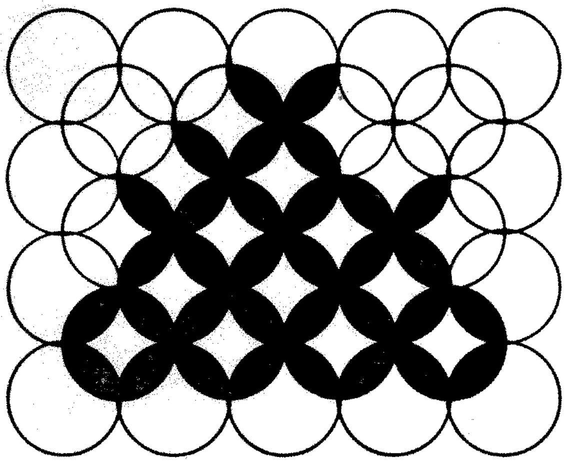

Fig. 3. Diagram showing how the square mesh of Fig. 2 is formed by the overlapping of virus protein disks arranged in a body-centred tetragonal lattice. In this figure the areas which overlap are mostly shaded in black, but some are left unshaded to show how they originate

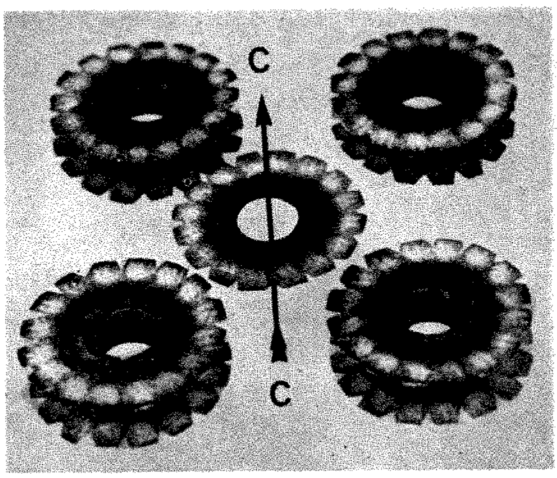

Fig. 4. Diagrammatic exploded view of the unit cell of the tobacco mosaic virus protein. The individual disks in this figure are copies of the radially averaged electron micrograph in reference No. 7

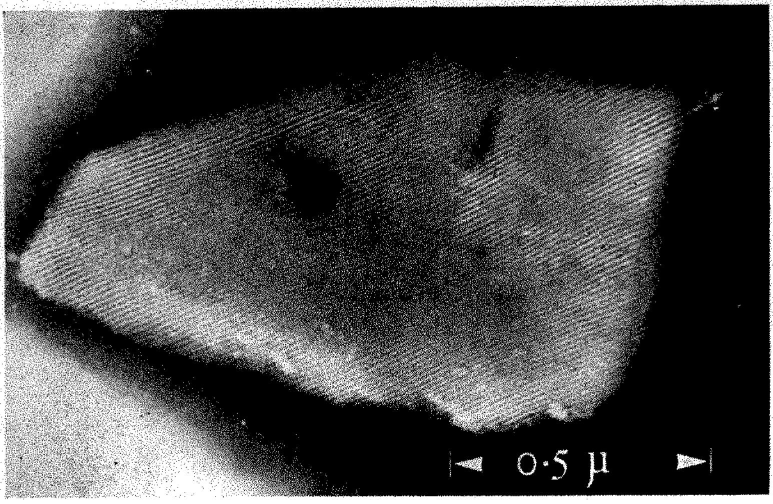

Fig. 5. Medium-sized crystal showing parallel lines on its surface

superimposed indefinitely using the same rules without altering the appearance of the image in any way, and it will be noted that if the disks have central holes this will not have much effect on the final image, because all such holes are situated over or under larger spaces in other layers of the lattice.

The interpretation of the structure of the crystalline plates seen in the electron micrographs is now obvious. They are evidently the (001) planes of tetragonal crystals. The edge of the square mesh was measured and was found to be approximately 100 Å, a value that was based on the previously measured magnification of the microscope. This would indicate that the centres of the disks are about 140 Å apart and that a certain amount of interpenetration or deformation has taken place during the formation of the crystals. The tetragonal habit is, of course, consistent with the 16-fold structure of the disks, and it is also consistent with the presence of the angles of 90° and 135° which are such a prominent feature of the edges of the crystals (Fig. 1). A diagram of the way in which the disks are packed in the unit cell is shown in Fig. 4. This unit cell contains two sets, probably two pairs, of disks, in which case it would have a molecular weight of about 1·6 million. For obvious reasons it was not possible to estimate the dimension of the *c* axis of the unit cell directly, but in the dried crystals it is probably about 70–100 Å, an estimate based on measurements of pairs of disks seen from the side.

Although most of the crystals exhibit a square lattice some have a rectangular one, and very thick crystals may only exhibit parallel lines (Fig. 5). This might be due to a slight deviation of the crystal lattice from true tetragonal form, but we are inclined to attribute it to minor distortion in the specimens and substrate.

The crystals appear to be formed during the dialysis of the alkaline solution of the '*A*' protein as an alternative to the polymerization to give the stacked disks and helical rods which are also to be found in the suspensions, and though small and thin are large enough to be seen under the optical microscope by phase contrast. The precise conditions favouring the formation of three-dimensional crystals at the expense of the two rod-shaped forms are not known, but are probably a function of the *p*H and ionic strength of the solutions. This is being investigated further.

This work was supported in part by a grant from the U.S. Public Health Service.

AGE AND SIGNIFICANCE OF DIABASE DYKE SWARMS OF THE CANADIAN SHIELD

By W. F. FAHRIG and R. K. WANLESS

Geological Survey of Canada, Ottawa

BASALT is the only abundant magma type thought to have been derived more or less directly from the Upper Mantle. In recent years the understanding of the petrology of this rock type has been enhanced through the study of basaltic provinces and through experimental work, particularly at the Geophysical Laboratory in Washington[1]. Diabase dykes of the Canadian Shield are thought to be chiefly tholeiites and representatives of one of the most common basaltic magma types. These dykes are so extensive in time and space that a broad survey of these intrusive rocks will provide additional information that will be useful in the integration of experimental and natural studies. The initial phase of the study of diabase dykes is concerned with the geometric outline of the swarms, with the age of the swarms and with the relationship of these features to the broad tectonic development of the continent. The first report of a potassium–argon study specifically aimed at the determination of the age of diabase swarms of the Canadian Shield is that of Burwash *et al.*[2].

The potassium–argon age measurements of diabase dykes used in this work were made on separated mineral fractions, chiefly biotite, and on whole-rock specimens of chilled dyke contacts and coarser-grained parts of dykes. Specimens from the chilled contacts generally yielded potassium–argon ages in excellent agreement with those of separated biotites. In one instance, a whole-rock potassium–argon age on coarse-grained material is 25 per cent greater than the best reasonable estimate of the age of the intrusion. Some of the averages reported here may be modified by additional work.

For convenience of reference the dyke swarms herein discussed have been numbered 1 to 13 on Figs. 1 and 2, proceeding roughly from the oldest to the youngest. The preliminary results of this dating programme are shown in Table 1.

Table 1

Dyke swarm	Material analysed	Average potassium–argon age
1	1 whole rock	2,485
2	4 whole rock 1 biotite 1 hornblende	2,150
3	2 whole rock 1 biotite	2,165
4	4 whole rock	2,090
5	4 whole rock	1,675
6	2 biotite	1,230
7	4 biotite 1 whole rock	1,315
8	2 biotite 2 whole rock	1,220
9	2 whole rock	1,030
10	2 whole rock	875
11	1 whole rock	790
12	3 whole rock	700
13	2 whole rock	640

These results indicate that diabase dyke swarms have intruded the Shield frequently throughout the span of Precambrian time.

The dimensions of some swarms and their changes in trend are so spectacular that they warrant special comment. Swarm No. 7, for example, extends over an area more than 1,000 miles long and locally more than 600 miles wide. Individual dykes of the swarm exceed 150 miles in length. The greatest concentration of dykes occurs in the Mackenzie District. Noteworthy changes in dyke orientation and concentration occur in this swarm as it passes from one structural province to another. The number of dykes in swarm No. 7 decreases in passing from the western parts of the Slave Province into the Bear Province, and the trend of dykes present in the Bear Province is more northerly. As a result, the swarm of dykes appears to converge and focus in a zone of dense intrusion and anomalously high gravity readings. South-east of Great Slave Lake dykes of swarm No. 7 show a change in trend as they enter an area shown by a dashed line on Fig. 2 where most of the potassium–argon ages are in the Hudsonian range of 1,700 million years but where occasional older dates have been reported[3]. Dyke swarm No. 8 is also spectacular in size, and north of Lake Superior the dykes of this swarm show a sweeping change in strike that suggests deflexion of the pattern of fracture around the boundary of the Southern Province.

The intrusion of dyke swarms Nos. 7 and 8 were igneous events of major significance in the middle Proterozoic history of the Shield. We suggest that many of these dykes penetrated the Earth's surface and vast outpourings of plateau basalt accompanied their intrusion. Probably hundreds of thousands of square miles of the Mackenzie District and the densely intruded areas of Ontario were covered by these outpourings. The detritus from the erosion of these flows would form a significant component in sediments being deposited in developing mobile belts adjacent to the craton.

If we accept the hypothesis that dyke swarms of regional extent were feeders to surface flows or near surface sheets, then periodically a blanket of tholeiitic lava was present

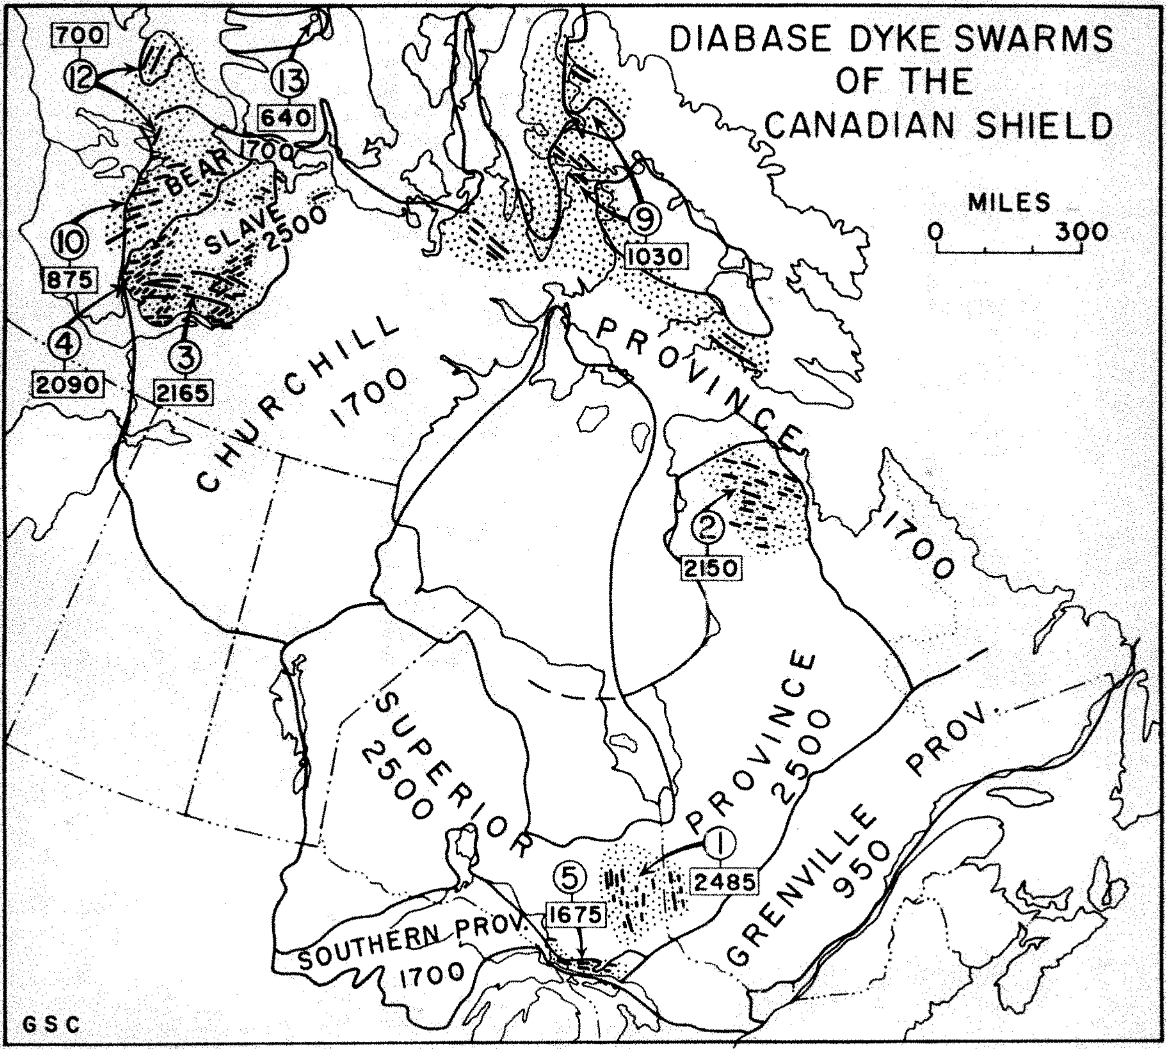

Fig. 1

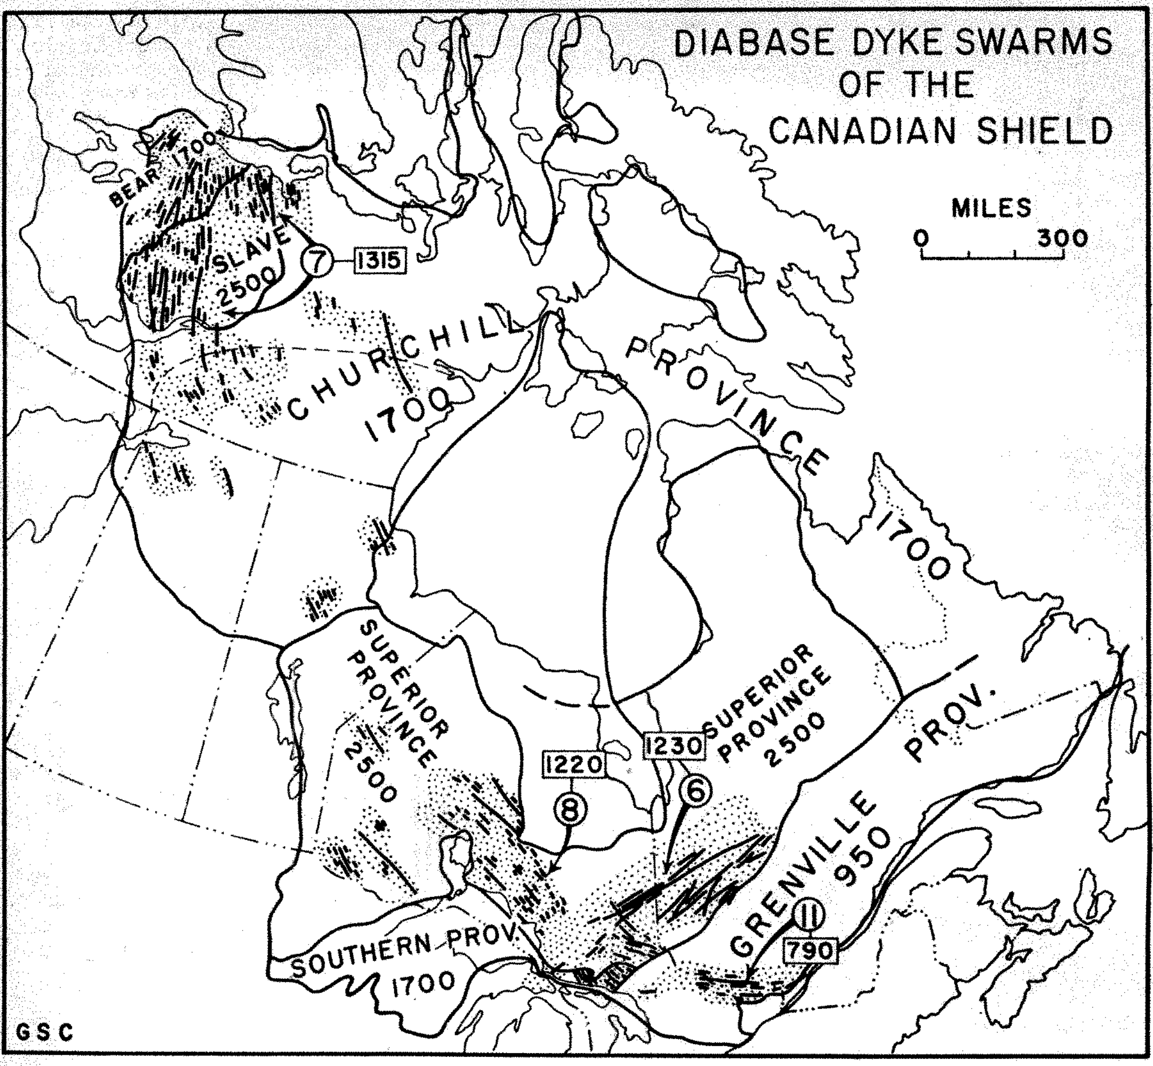

Fig. 2

at or near the surface of the Shield. Significant amounts of sialic crustal material could then be derived from the craton underlying these flows or sheets only after they had been removed by erosion. Basaltic cover rocks believed to possess a low rubidium–strontium ratio may therefore have contributed significant quantities of clastic materials to marginal basins and these could therefore influence the observed strontium-87/-86 ratio now found in younger metamorphic terrains.

In addition to this effect, under suitable climatic conditions, the erosion of the basaltic cover rocks or near-surface diabase sheets would release large quantities of more soluble material for precipitation in surrounding miogeosynclines. The great Precambrian deposits of iron-formation in the Shield may derive their iron not from the contemporaneous volcanic extrusions of the newly forming orogenic belt, but chiefly from the erosion of somewhat older tholeiitic lavas or near-surface sheets fed through fissures on the neighbouring craton. These outpourings probably represent the terminal activity of a previous orogenic cycle and in a tectonic sense are fundamentally different from the basalts of the developing eugeosyncline. Furthermore, in comparison with dyke-fed tholeiitic flood basalts, the surface areas of older infolded basalts of the Shield, for example, the Keewatin-type basalts, would be insignificant. This idea is particularly attractive as it appears to deal successfully with the two major problems in the genesis of this type of sedimentary iron-formation, namely, the banding of the iron-formation and the virtual restriction of this type of iron-formation to the Precambrian. If the iron is released by sub-aerial weathering of plateau basalt, the banding can be related to the yearly weathering cycle, and the rarity of iron-formation of this type in the Phanerozoic can be ascribed to a relative paucity of flood basalts on the craton during Phanerozoic time or to inappropriate climatic conditions or to both. The sub-aerial weathering of tholeiitic basalt would, as compared with the weathering of the average Shield rock, result in a much lower proportion of resistates. This is compatible with the character of Precambrian iron-formation.

It is interesting to speculate on the possible large-scale tectonic significance of dyke swarms. In some instances the trends of the swarms appear to be perpendicular to the directions of compression present during the orogenic episodes that immediately preceded dyke intrusion. For example, swarms 2 and 3 are roughly parallel to structural trends, and perpendicular to the direction of compression in the Superior province. Swarm 6 probably lies perpendicular to the direction of compression of the crust in this area during the Hudsonian orogeny. Swarms 7 and 8 parallel the western and southern boundary of the Shield and probably lie perpendicular to a middle Proterozoic compression.

It is suggested that elastic rebound of the crust after a period of crustal compression may result in low-pressure belts into which basaltic magma is introduced. We suggest that intense folding and compression in the orogenic belt and less intense compression within the craton results from sub-crustal currents. If relaxation occurs during or after a major orogenic cycle, as a result of diminution in size of sub-crustal currents, diabase dyke intrusion may occur both in the orogenic zone and in the adjacent stable craton If a period of tension is succeeded by additional mountain building accompanied by folding, metamorphism and granitic intrusion in the orogenic belt, diabase dykes related to the preceding period of tension will be preserved or recognizable only in the stable craton A series of dyke swarms in the craton may reflect more intense rhythmic compression and relaxation in neighbouring developing mobile belts

The examination of dyke swarms promises also to be of value in the interpretation of certain geochronological events in the development of the Shield For example, it is noted that dykes of swarms Nos 2 and 3 are the same age within limits of analytical uncertainty and they exhibit concordant trends If these trends are projected, the dyke swarms of approximately 2,200 million years could pass through the main body of the Churchill Province, in an area where potassium–argon dates are generally within the 1,700 million year range of the Hudsonian orogeny Stockwell[4] has reported that, within the Churchill Province between Nonacho Lake south-east of Great Slave Lake and eastward toward Hudson Bay, a number of potassium–argon ages ranging from 1,900 to 2,460 million years are present among more common Hudsonian potassium–argon ages of 1,700 million years He has interpreted these as survival dates from the Kenoran orogeny which affected this area about 2,500 million years ago Within this part of the Churchill province the younger dykes of swarm No 7 at 1,315 million years are prominent, but metamorphosed segments of older east–west dykes are also relatively common These may represent the extension of the pre-Hudsonian swarms Nos 2 and 3 through the Churchill Province If this is the case, doubt is cast on the idea that the Slave and Superior Provinces were originally isolated continental nuclei

OBITUARY

Prof. Jacques Hadamard, For.Mem R S

JACQUES SALOMON HADAMARD was born in Versailles on December 8, 1865 His mathematical abilities very soon became evident when he won the entrance examination to the École Polytechnique, perhaps the stiffest mathematical entrance examination in the world, with a record of 1,875 marks out of a total of 2,000 After graduation he obtained a teaching post at the University of Bordeaux, but soon returned to Paris as a professor at the Sorbonne In 1897 he went to the Collège de France, from which he retired in 1935 The Second World War forced him to go to the United States, where he found a temporary home in Princeton In 1945 he visited Great Britain and gave a charming lecture on personal recollections as a mathematician, which is still remembered with pleasure by many of his British colleagues He soon returned to Paris, leading a very active life in spite of his old age, until he died on October 17 in his ninety-eighth year

Most of his work in pure mathematics was done in the 1890's on analysis Hadamard, desiring to investigate the Riemann ζ-function, developed a theory of integral functions of a complex variable which has been the foundation of all the subsequent work on the subject In 1896 he proved the prime number theorem which had been conjectured by Gauss and Legendre a hundred years earlier let $\pi(x)$ be the number of primes not exceeding x, then $\pi(x) \sim x/\log x$ The same result was proved simultaneously by de la Vallée-Poussin Though a lot of work has since been done on the prime number theorem, Hadamard's proof is still the simplest and most natural proof of the theorem It must be a unique event in the history of science that a major break-through is achieved simultaneously by two scholars who each survived their achievement by two-thirds of a century

A few other results can be briefly mentioned

(1) Hadamard's inequality for real determinants

$$\|a_{ik}\|^2 \leqslant \prod_{i=1}^{n} \sum_{k=1}^{n} a_{ik}^2$$

(2) Hadamard's "3 circle theorem" let $m(r)$ be the maximum of the absolute value of a regular complex function in a circle with fixed centre and radius r Then $\log m(r)$ is a convex function of $\log r$

(3) Hadamard's gap theorem for a Taylor series of the form

$$\sum_{n=0}^{\infty} a_n x^{b_n}$$

Every point on the boundary of the circle of convergence is a singular point of the function if $b_{n+1} - b_n \rightarrow \infty$

His work in applied mathematics was mainly concerned with wave propagation and is of classical importance No standard text on the fluid mechanics of high-speed flows, for example, would be complete without basic reference to it, nor would any account of Huygens's principle Its influence permeates present-day thinking on solutions of the wave equations and allied problems Starting from the work of Riemann, Kirchhoff and Volterra, he developed in 1903 (ref 3) and in his later work in 1923 and 1932 (refs 4 and 5) the theory of hyperbolic linear differential equations for the general case of n independent variables, distinguishing between the cases when n is odd and even Here in these books are set out the tools in the form of the theory of characteristics and bicharacteristics, the principle of descent and the concept of the finite part of an infinite improper integral, without any of which an understanding of high-speed flows would be impossible Hadamard was not only interested in existence and uniqueness properties, but also, as Friedrichs remarks, in the property of the continuous dependence of the solution on the data, a property which is required if the problem is to be called correctly posed With the advent of modern computational techniques the application of the method of characteristics has become a standard method of solution not only for linear but also for quasi-linear hyperbolic differential equations, and three-dimensional aerofoil theory leans heavily on the concept of the finite part of an infinite integral

Hadamard's name must also be linked with those of Stokes, Earnshaw, Riemann, Rankine, Hugoniot and Rayleigh in developing the ideas of non-linear wave motion which led to the present theory of shock waves and their formation

Hadamard's merits as a mathematician were fully recognized at home and abroad He held many honorary doctorates and was an honorary member of many learned societies, in particular a foreign member of the Royal

Society and an honorary member of the London Mathematical Society.

Hadamard published the following books: (1) *La série de Taylor et son prolongment analytique* (Paris, 1901), (2) *Notice sur les travaux scientifiques de M. Jacques Hadamard* (Paris, 1912), (3) *Leçons sur la Propagation des Ondes* (Paris, 1903), (4) *Lectures on Cauchy's Problem in Linear Partial Differential Equations* (Yale, 1923, also Dover Publications, 1952), (5) *Le problème de Cauchy et les équations aux derivées partielles linéaires hyperbolique* (Paris, 1932), (6) *An Essay on the Psychology of Invention in the Mathematical Field* (Princeton, 1945).

L. HOWARTH

NEWS and VIEWS

Electronics at the University of Southampton:

Prof. E. E. Zepler

E. E. ZEPLER became the first head of the Department of Electronics on its creation in the then University College of Southampton shortly after the end of the Second World War. In 1949 he was elected to the newly established chair of electronics at the College, thus becoming the first professor of electronics with an independent department in Britain. Zepler's earlier experience with Telefunken in Germany (1925–35), where he became head of receiver and direction finder design, with the Marconi Co. in England (1935–40) and at the Cavendish Laboratory during the War, fitted him admirably for the post. The present time sees him leaving a thriving department with strong postgraduate teaching and research schools as well as undergraduate courses designed both for scientists and for engineers. His keen interest in electronics teaching found a further outlet in his associations with the British Institution of Radio Engineers, the educational policy of which was formed largely under Zepler's influence. He was elected president of the Institution in 1959–60 and still serves on the Council of the Institution as a vice-president, as well as on several of its committees. Zepler is also well known as the author of *Radio Receiver Design* and more recently as the co-editor (with S. W. Punnett) and part author of two further books concerned with *Electronic Circuit Techniques* and *Electronic Devices and Networks*. His publications also include, however, several books concerned with chess and chess problems. He is an outstanding chess player, having represented both Essex and Hampshire in tournaments since settling in Britain in 1935. Zepler's lively personality and his friendliness to all who have come into contact with him will not easily be forgotten, and it is a source of great pleasure to his many friends that in retirement he will continue to be associated with the University as a Senior Research Fellow in the Institute of Sound and Vibration Research.

Prof. G. D. Sims

DR. G. D. SIMS of the Department of Electrical Engineering, University College, London, has been appointed to succeed Prof. Zepler. Dr. Sims studied in both the Physics and the Mathematics Departments of the Imperial College of Science and Technology from 1945 until 1948, obtaining both a B.Sc. in physics and an M.Sc. in mathematics. From 1948 until 1954 he was at the Hirst Research Centre of the General Electric Co., where he worked on a number of projects, including the use of the H_{01} waveguide mode for long-distance transmission and some problems of magnetron operation. During this period he also worked part-time at Imperial College with Prof. D. Gabor on magnetron instability phenomena and presented a Ph.D. thesis on this subject. From 1954 until 1956 he was with the Theoretical Physics Division at the Atomic Energy Establishment, Harwell, and was attached to the Particle Accelerator Group (now the Rutherford High Energy Laboratory). Two years later he joined the staff of the Electrical Engineering Department at University College, London, and, while taking a full part in the teaching of the Department, continued his interest in research by supervising a number of postgraduate research projects. These interests included plasma problems, the direct conversion of heat to electricity using thermionic diodes, and a number of microwave valve investigations. Dr. Sims took up the chair of electronics at the University of Southampton in October.

Physics at the University of Leeds:

Prof. E. C. Stoner, F.R.S.

PROF. E. C. STONER retired on September 30 from the Cavendish Chair in Physics in the University of Leeds after nearly forty years' service in the University. Born at East Molesey in 1899, he went up to Cambridge from Bolton School, took firsts in both parts of the Natural Science Tripos and within little more than three years from graduation had published a valuable experimental paper (with L. H. Martin) and a theoretical one ("The Distribution of Electrons among Atomic Levels") which was to play a decisive part leading towards the enunciation of the 'exclusion principle'. In the years to follow, his most important contributions were in the field of magnetism, here his two books were to be recognized as standard works, while of his many notable original papers those in 1938–39 on collective electron ferromagnetism were perhaps outstanding. In recent years he has encouraged a wide-ranging approach in his laboratory to problems of electronic band structure in metals. Stoner went to Leeds as a lecturer in 1924, was appointed to a readership in 1927, to a newly instituted chair of theoretical physics in 1939 and to the Cavendish chair in 1951. He held a fellowship of his college, Emmanuel, from 1928 until 1931, and was elected a Fellow of the Royal Society in 1937. Throughout his service in Leeds he taught actively, in recent years in stimulating lecture courses in quantum mechanics and statistical mechanics. He played a leading part in the formulation of post-war university policy and in all the ensuing quinquennial surveys, served as a vice-president of the [then] Institute of Physics and, very effectively, on the Post Graduate Training Awards Committee of the Department of Scientific and Industrial Research.

Isidore Geoffroy St. Hilaire Medal for 1963

MISS PHYLLIS BARCLAY-SMITH has been awarded the Isidore Geoffroy St. Hilaire Medal for 1963—so far as we are aware, the first occasion that it has been given to a woman. This Medal is awarded annually by the Société National de Protection de la Nature et d'Acclimatation de France to a person whose nationality is not French and who is distinguished for work in this field. The Medal is being presented at a general meeting of the Society, which will be held on December 8 in the Grand Theatre of the Museum National d'Histoire Naturelle, Paris. Miss Barclay-Smith has a long record of various public activities, mainly on behalf of bird preservation. She has been the secretary of the International Council for Bird Preservation since 1946 and is a member of the Home Office Advisory Committee on Protection of Birds for England and Wales. As honorary secretary of the Co-ordinating Advisory Committee on Oil Pollution of the Sea, she took an active part in the promotion of international legislation to prevent the discharge of oil and oily waste products into the sea.

Technical Teacher Training

A POLICY statement entitled *Technical Teacher Training*, issued by the Association of Teachers in Technical Institutions and based on a report prepared by the Association's Education Committee, concludes that untrained teachers have been too readily accepted in the past and that the training of teachers is essential to ensure effective use of expenditure on further education (Pp. 24. London: Association of Teachers in Technical Institutions, 1963). It recommends that, as soon as possible, all new entrants to technical teaching, both full-time and part-time, should receive professional training and normally a full-time one-year course. A recognized professional qualification of technical teachers is recommended and suitable training schemes should be developed for regular part-time teachers, whose salary scales should provide financial recognition of professional training. Experienced members of staff should be given the responsibility of guiding and assisting new entrants, and grants to trainee teachers should be closely related to what they may reasonably expect to earn on appointment. Refresher courses should be provided for certain teachers and for those courses subsistence grants should be paid, while supplementary courses in general education should be provided to help meet the demand for teachers for craft and technician courses. Better liaison facilities are required between technical colleges and technical teacher training colleges, and the salaries paid in the latter must be sufficient to attract some senior staff from the former. While there is room for experiment with sandwich courses in teacher training, more experience is required for a final judgment. Existing teachers should be encouraged to improve their qualifications, and emphasis is laid on the need for much more research into problems of further education. Educational fellowships in all types of educational institutions are advocated to enable teachers to undertake educational research. Besides further extension of the existing technical teacher training colleges, at least two new colleges are required, one in the north-east and one in the south-west of Britain, and it is suggested that training departments should be opened in colleges of technology and some technical teaching training given in university departments of education. The new 'staff college' should cater for all fields of further education and for those concerned with educational administration and industrial training.

The Advancement of Science in India

THE Indian Science Congress Association has issued as a reprint the text of Dr. D. S. Kothari's presidential address, "Science and the Universities", given at the fiftieth session of the Congress at Delhi during October 7–10, 1963 (Pp. 17. Calcutta: Indian Science Congress Association, 1963). Dr. Kothari begins by quoting the Prime Minister's statement on scientific policy five years earlier and then discusses the implications of what he terms the 'current scientific revolution', in which the doubling period of science is about fifteen years in terms of co-operation and the unpredictability in the march of events. Not merely does it mean that some 90 per cent of scientists who have ever lived are alive to-day, but also that the time-gap between basic discovery and its application is continually diminishing. The gap between the richer and poorer countries, the developed and the underdeveloped countries, is widening rapidly, so that it is increasingly difficult for the developing countries to import the capital equipment and machinery needed to raise their production. This situation is detrimental to the interests of both developed and underdeveloped countries, but it is possible for the developed country to make major contributions to the rapid development of a newly developing country by supplying the initial nucleus of technical exports and material resources. Dr. Kothari recognizes that research and development expenditure is not an entirely satisfactory index of the development of science in a country, but there is a close and direct connexion between the percentage of national income spent on research and development and the number of scientists and technologists expressed as a percentage of the population. Stressing then the contribution of the universities to scientific advance, both in teaching and in research, Dr. Kothari refers to the unity of science and the danger of fragmentation, the imperative importance of a climate of free enquiry, the growing significance of team-work and the problems presented in the allocation of resources. These are the considerations which indicate where the universities can contribute most decisively to the scientific interests of a country, and finally he emphasizes the value, in a country of limited resources like India, of the centres of advanced study which the University Grants Commission was seeking to establish.

Higher Education in India

THE report of the University Grants Commission to the Government of India for the year 1961–62 records an increase in the number of universities from 33 to 46 during the Second Plan period, and with the five established during the year the total is now 51, of which 35 are affiliated, 14 unitary and 2 federal in character (Pp. v+36. New Delhi: University Grants Commission, 1963. Rs. 1.50; 3s. 6d., 54 cents). Several steps were taken in the development and expansion of engineering and technological education in the universities, and a Committee was appointed to make a thorough study of standards prevailing generally, while another Committee is considering the selection of some twenty centres of advanced study in various universities. The Commission continued to be concerned with examination reform and measures for promoting general education, and has offered assistance in organizing summer schools, institutes, conferences and seminars in different subjects. Great importance is attached to the development of the affiliated colleges in which about 86 per cent of the university students in the country are enrolled, and where the organization of postgraduate teaching presents problems. Some twenty-two State universities are now participating in the Commission's scheme for raising salary-levels to that of the central universities. The number of students increased by 11 per cent to 1,156,000, the increase of women students, now 186,030, being particularly notable, and the overall increase was shared by all faculties, the percentage increase being greatest in agriculture (78.6), engineering and technology (56.8), medicine (48.2) and education (46.7). Postgraduate students increased in number from 63,000 in 1960–61 to 72,859 (22 per cent of whom were studying science subjects): the total has almost doubled in the past five years. The percentage of failures in 1960 varied from 57 per cent in the B.A. examination, 50.8 per cent in the B.Com., 49 per cent in the B.Sc., and 46.6 per cent in the M.B.B.S. to 13.7 per cent in the B.Sc. (Tech.), but many successful candidates secured only minimum marks.

Organization of Scientific Research in Poland

IN a brief survey of the development of scientific research in Poland, published in *Polish Facts and Figures* (No. 729, October 19, 1963), Prof. I. Malecki refers to considerable changes in the scope and organization of research in Poland since 1952. Between 1950 and 1963 industrial production increased 3.7 times and there are now 172,000 students in 73 universities and specialized colleges, which employ 16,300 scientific workers, while the Polish Academy of Sciences employs 6,200 persons (including 500 professors and assistant professors), compared with 2,000 in 1953; 21 research institutes and 56 laboratories are now attached to the Academy. The two institutes of nuclear research, while under the scientific supervision of the Academy, are controlled by the High

Commissioner for Nuclear Energy The institutes attached to the Academy are mainly responsible for oriented fundamental research, while in the universities emphasis is laid on free basic research Applied research and technological development are conducted mainly in the industrial research institutes, the research staff of which has increased seven-fold in the past decade. The Polish Academy of Sciences is responsible for planning and co-ordinating fundamental research, and especially for long-term plans for developing science The general co-ordination of applied research and technical development is the responsibility of the Committee for Science and Technology established in 1963, which is also responsible for the finance of research and for the development of scientific manpower Scientific co-operation with foreign countries is regarded as an important element in the contemporary development of science, and the Academy's institutes have established numerous contacts with scientific institutions abroad In 1962, 94 Polish scientific workers went to Britain on behalf of the Academy and 74 British scientific workers went to Poland at the Academy's invitation

The American Academy of Arts and Sciences

THE *Records of the American Academy of Arts and Sciences, 1962–63*, comprises the usual lists of officers and committees, lists of members by classes and alphabetical, including new members elected on May 8, 1963, the statutes, records of meetings 1962–63, and the annual reports of committees (Pp 152 Boston, Mass American Academy of Arts and Sciences, 1963) The last-mentioned section includes one from the Committee on Pugwash Conferences on science and world affairs The sub-committee for international conferences has been reconstituted as a new full Committee on Pugwash Conferences on Science and World Affairs with a Sub-Committee on Informal International Conversations among Scientists

The National Museums of Southern Rhodesia

THE National Museums of Southern Rhodesia include three museums, in Bulawayo, Salisbury and Umtali The year 1962 witnessed the completion of the building programme of the Museums of Southern Rhodesia inaugurated in 1960 (Report of the Trustees and Directors of the National Museums of Southern Rhodesia for the year ended December 31, 1962 Pp 22 Salisbury and Bulawayo National Museums of Southern Rhodesia, 1963) At the present time, there are new museums in all three centres The full programme has cost £450,000 and the raising of this amount in a time of financial stringency has been no mean achievement The generous assistance of the big Mining Corporations, the State lotteries and Municipal contributions made this possible Pre-occupation with the building projects has of necessity meant the curtailment of the usual field-work and research activities Many of the recommendations of the three Fulbright Scholars who were at the Museum in 1961 have come to fruition These include the re-stocking of the National Parks where wild-life no longer existed, the utilization of wild-life as a source of protein, and the establishment of a postgraduate course on wild-life conservation at the University College

Simplified Gas Chromatography

THE 'Junior' gas chromatograph produced by Messrs Gallenkamp is a robust instrument designed specifically for teaching purposes but with a performance adequate for any routine industrial applications The new apparatus is expected to satisfy all the requirements of universities and technical colleges in which the theory of gas chromatography is combined with practical work Both gases and liquids with boiling points up to 80° C can be analysed The sample is introduced by syringe on to an unheated, general purpose, coiled silicone column The thermistor katharometer is powered by a long-life battery and is very stable and extremely sensitive Peaks may be plotted either by using a galvanometer or by the recommended 6-in strip chart recorder The detection limit of the katharometer is about 10^{-7} g and chromatograms can be obtained from about 10 µl liquid or 0 5 ml gas

Radioactivity in Drinking Water in the United Kingdom

THE report entitled *Radioactivity in Drinking Water in the United Kingdom. 1962 Results* gives measurements made under the Government's programme for monitoring radioactive fall-out in drinking water (Pp 24 London H M S O, 1963. 1*s* 9*d* net) Like the previous four reports in the series, it contains the radiostrontium and radiocæsium results obtained, and, in addition, details are included of investigations into the levels of other fission products in drinking water Because of the nuclear weapon tests during 1961, the amount of strontium-90 in drinking water rose above the 1961 level to about the 1959 level (which reflected the results of tests made during 1958) The concentrations of strontium-90 and of cæsium-137 were measured regularly in twenty-four public drinking waters Practically no concentration was found in deep well waters at Brighton and Wolverhampton and low concentrations in the Folkestone supply In the river-derived waters the average level of strontium-90 was 0 36 pc /l, but in the water derived from the chalk stream of the River Itchen at Southampton the concentration was again much lower, 0 065 pc /l. The average daily ingestion of strontium-90 and cæsium-137 is estimated at 0 41 pc per person and 0 16 pc per person, respectively These amounts represent less than 5 per cent and 1 per cent, respectively, of the average daily intake of these radionuclides in the diet It has been confirmed that strontium-90 is the most important of the fission products in drinking water to be determined and that when the levels of iodine-131 rose in milk during 1961 and 1962, following the commencement of nuclear tests, the rise in drinking water was negligible

Assay of Strontium-90 in Human Bone in the United Kingdom

IN its *Monitoring Report Series*, the Medical Research Council publishes, at six-monthly intervals, the results of analyses of strontium-90 in human bone samples, mainly from subjects who have died during the period under review The analyses are carried out by the Atomic Energy Research Establishment and by research workers in Glasgow and Cambridge No 6 in the Series surveys results for the first half of 1962, and No 7 for the second half (No 6 *Assay of Strontium-90 in Human Bone in the United Kingdom · Results for 1962* Part 1, with some Further Results for 1961 Pp iii+15 No 7 *Results for 1962* Part 2 Pp ii+17. London H M S O, 1963 1*s* 6*d* net each part) In No 6 there are some results for 1961 representing the first instalment of a new project designed, in collaboration with the West London Coroner's office, to give information about the population of London and its environs During 1962 there was no survey of bone samples obtained through the Coroner, but analyses have been resumed during 1963 and will be reported next year The average amounts of strontium-90 in bone were approximately the same for all age groups during the first half of 1962 as previously, but an increase in the level was observed in samples from new-born (including still-born) infants and children aged 0–4 years in both the Atomic Energy Research Establishment and the Glasgow records for the period July–December 1962 The rise, which has been delayed longer than expected, is a result of the nuclear weapon tests carried out in the autumn of 1961 For the infants the average amount of strontium-90 was 1 37 pc /g calcium, that is, 1 37 strontium units and 2 5 for children in the 0–4 age group, compared with 0 78 and 1 34, respectively, for the corresponding period in 1961 The highest value recorded during the year was 7 5 strontium units, but this value is suspect, and excluding this result the highest value is 3 6 units compared with 3 5 of the previous year At the end of July 1962 analyses of bone at Cambridge were discontinued The reports contain summary tables giving details of the samples and the results of their analyses, together with the types of counter and counting methods used

Relief-radiography of Bladder Tumours

A METHOD of relief-radiography of bladder tumour by means of a 76 per cent solution of 'Urografin' has been described by Prof Naotomo Oka and Tadashi Kato, of the Department of Urology, Nagoya City University Medical School, Japan (*Nagoya Medical Journal*, 8, 3, December 1962) The method is simple to operate and the shadow or contour of the bladder tumours is clearly shown up The method is suitable for displaying other disorders of the bladder, such as prostatic tumours, trabeculation and irregularities after operations

Experimental X-ray Crystallography

AN international summer school in "Experimental X-ray Crystallography" will be held in Castel Tenno, Riva del Garda, Italy, during August 31–September 12, 1964 It will consist of a course of lectures and demonstrations intended for crystallographers concerned with single crystals Only a slight acquaintance with the subject will be assumed and all subject-matter will be treated in a fundamental manner Attention will be directed to the orientation of crystals by various photographic and diffractometer methods For this purpose the theory and application of the stereographic projection and of the reciprocal lattice will be dealt with The treatment will start from the simplest and finish with the most general problems The theory of the use of diffractometers, particularly the main automatic types, will be explained, and in the demonstrations the student will interpret data obtained from such instruments and work out programmes for transfer to digital computors These programmes will include the various corrections which are essential The use of photographic methods for the examination of the intensity of X-ray reflexions will be discussed and also the possibilities and limitations on the use of microdensitometers Students will not use X-ray diffraction apparatus though some instruments will be available for purposes of demonstration The lectures will be given by Dr W A Wooster, formerly of the Department of Mineralogy and Petrology, Cambridge, and he will be assisted in the demonstrations by Dr Nora Wooster, Mr A M Wooster and Mr G A Wooster The lectures will be given in English, but provision will be made for those who indicate their wish to use French or German The inclusive charge for the course of lectures and demonstrations will be 115 dollars, or 110 roubles, or 70,000 It lire, or £40 This sum does not include hotel charges Those interested should apply to Dr W A Wooster, Brooklyn Crystallographic Laboratory, Bottisham, Cambridge, and a second notice will be sent to all who indicate their wish to join such a course not later than January 7, 1964

University News·

Birmingham

THE following appointments have been announced *Lectureships* Dr G M Butler (botany), Mr D A. Jones (genetics), Dr A Macdonald (chemistry), Dr C J Beevers (physical metallurgy), Dr H O Berktay (electrical engineering), Dr R J Bland (electrical engineering); Mr M A Brebner (computing in the Department of Mathematical Physics), Dr H Kaliszer (mechanical engineering); Dr R Lazenby (computing in the Department of Mathematical Physics), Mr H C Wilkie (pure mathematics), *Research Fellowships* Dr N Baggett (Imperial Chemical Industries Research Fellow in the Department of Chemistry), Dr C A Barson (Senior Research Fellow in the Department of Chemistry), Dr P S Dobson (physical metallurgy), Mr J W Edington (physical metallurgy), Mr W J Feast (chemistry), Mr C I Harris (biochemistry), Mr I R Harris (physical metallurgy), Dr M H B Hayes (Senior Research Fellow in the Department of Chemistry), Mr B E Job (chemistry), Mr C D. Lewis (engineering production), Dr G S Prosser (chemistry), Mr J W G Wilson (electron physics), Mr D A Woodford (physical metallurgy), Mr G A Young (geology).

St. Andrews

THE following appointments to lectureships have been announced (1) St Salvator's College, P E Gibbs (botany), Dr R B Thomas (theoretical physics), Dr J R MacCallum (chemistry), Dr H C McGregor (zoology) (2) Queen's College, Dr C R Allen, Dr W K Busfield, Dr J W Falconer, Dr P A Warsop and Dr T J R Weakley (chemistry), R J Jarvis and Dr R M Dicker (mathematics) Dr R Foster has been appointed senior lecturer in chemistry at Queen's College

Announcements

THE following have been appointed trustees of the British Museum (Natural History) Prof O M B Bulman, professor of geology, University of Cambridge, Prof H G Callan, professor of natural history, University of St Andrews, and Sir Landsborough Thomson, chairman, Executive Committee, Council for Nature

A SYMPOSIUM on the "Utilization of Metallurgical Wastes" will be held at the National Metallurgical Laboratory, Jamshedpur, during February Further information can be obtained from the Director, National Metallurgical Laboratory, Jamshedpur 7

THE fourth Rankine Lecture of the British National Society of Soil Mechanics and Foundation Engineering entitled "Long-term Stability of Clay Slopes" will be delivered by Prof A W Skempton at the Institution of Civil Engineers on February 5 Further information can be obtained from the Secretary, British National Society of Soil Mechanics and Foundation Engineering, Institution of Civil Engineers, Great George Street, Westminster, London, S W 1

A SYMPOSIUM on "Neutron Dosimetry for Radiological Purposes", arranged by the Institute of Physics and the Physical Society on behalf of the Joint Health Physics Committee, will be held at the Royal Aeronautical Society, London, on January 24 The symposium will include five main sessions the interaction of neutrons with tissue, flux and energy measurement, determination of absorbed dose in tissue, measurement of dose equivalent (formerly RBE dose), dosimetry of high-energy particles Further information and forms of application can be obtained from the Administration Assistant, Institute of Physics and the Physical Society, 47 Belgrave Square, London, S W 1

ERRATUM Certain errors were made in the obituary notice of Prof J F Piccard (*Nature*, **199**, 229, 1963) Prof Piccard's widow, Dr Jeannette Piccard, writes as follows "Jean received an honorary Dr Sc degree from Jamestown College, North Dakota, in 1957 He also received an honorary Dr Sc from the University of Southern Illinois in 1959 He never received an honorary degree from the University of Strasbourg nor the United States Distinguished Service Award Auguste Piccard, Jean's twin brother, received the degree from Strasbourg in 1932 Jacques Piccard, the son of Auguste, received the U S Distinguished Service Award in 1960 The American Meteorological Society honoured Jean, not for his scientific balloon flight but for the invention design, and construction of the modern plastic balloon so widely used as a research tool to-day He did this with a research grant of 600 00 dollars from the University of Minnesota in 1936 It is easy to confuse the many accomplishments of the different members of the Piccard family "

MARINE ECOLOGY AND PALÆOECOLOGY

"TO provide discussion between botanists, zoologists and palæontologists on subjects of mutual interest by comparing analogous living and fossil assemblages" was the principal purpose of a symposium on marine ecology and palæoecology which was held by the Systematics Association in the Department of Zoology and Wadham College, Oxford, during September 24–26. The meetings were attended by about 130 people, of whom just more than half were palæontologists, and there was useful interchange between disciplines that enjoy far too little contact.

The first paper was by Prof. O. M. B. Bulman (Cambridge), who discussed the mode of life of the extinct non-dendroid graptolites. A pelagic habit is immediately suggested by (1) their wide distribution (in some cases almost world wide), (2) their occurrence in all types of matrix, (3) their most characteristic occurrence in black shales which seem to represent deoxygenated bottom mud lacking in benthonic organisms. There appeared to be very little concrete evidence of attachment of the 'true' (non-dendroid) graptolites to floating weed, or of common floats for synrhabdosomes which had been postulated by Ruedemann. A variety of buoyancy devices had been attributed to them, such as vesicles, webs between the branches and, in some, triple-vaned structures at the end of the nema. Prof. Bulman suggested that, of the various possible buoyancy mechanisms, the most likely in the majority of graptolites was the presence of gas bubbles in the soft tissue which is now generally accepted as covering the graptolite skeleton in life.

In the discussion which followed, Mr. C. W. Wright (London) suggested that the three-vaned structures, said by some to be buoyancy devices, were more likely to be attitude-maintaining devices, particularly since the posture of most graptolite rhabdosomes appear to have been highly important.

Similar evidence of a pelagic mode of life was presented by Dr. R. P. S. Jefferies (British Museum (Natural History)), for the Jurassic lamellibranch '*Posidonia*'. He considered two species, *Bositra buchi* (= *Posidonia ornati* et *P. alpina* auctt.) and '*Posidonia*' *radiata* (= *P. bronni magna* auctt.). Like graptolites, they commonly occur in black shales with few benthonic associates, but also occur sporadically in limestones and sandstones with much benthos. This strongly suggests they were not benthonic.

Granted this, Dr. Jefferies thought that both were probably pelagic swimmers, rather than living attached to flotsam. Thus, in *B. buchi* there was an anterior and posterior gape, suggesting swimming ability by analogy with Recent relatives, no sign of attachment in the shell outline at any growth stage and a shell thickness (60μ) comparable with Recent pteropods.

A nekto-planktonic mode of life for '*P.*' *radiata* was suggested by Hauff's observation that it became abundant when normal benthos disappeared but that it was then much more abundant than such 'benthos' as *Ostrea*, *Inoceramus dubius* and *Pentacrinus* that occurred attached to driftwood.

Swimming ability might be primitive in scallops, since Recent *Lima* and *Pecten* both swim in much the same way and also early Pectinacea were probably active as they have few epizoa and the shape of the shell sometimes suggested swimming ability.

After the paper, Prof. C. M. Yonge (Glasgow) commented that Recent scallops could swim only intermittently. Dr. Jefferies replied that experiments suggest that a pelagic mode of life for '*Posidonia*' was as feasible as for a Recent pteropod.

Mr. N. Tebble (London) was sceptical of the evidence for a pelagic habit in '*Posidonia*', remarking that there was just as much evidence that the sand-living species *Tellina tenuis* is planktonic, which it certainly is not. Dr. Jefferies replied that it was facies that showed that '*Posidonia*' was not benthonic.

Dr. J. A. Allen (Cullercoats) pointed out that there was often an epifauna on Recent *Chlamys septemradiata*, a good swimmer. Dr. Jefferies replied that perhaps early Pectinacea were even more active than the species cited.

Turning to a study of living forms which is proving of particular interest to palæontologists, the meeting heard a paper by Dr. E. J. Denton and Dr. J. B. Gilpin-Brown (Plymouth, and the University of Auckland, New Zealand) on the buoyancy of *Sepia* and *Nautilus*. They showed that *Sepia* changed its specific gravity according to the light, and was more buoyant at night time. This buoyancy is controlled by changes in the relative gas and liquid spaces in the chambers of the cuttle bone. In the older chambers the gas pressure is always about 0.8 atmospheres whatever the depth, but the liquid inside the chambers becomes less saline as depth increases, indicating an adjustment of osmotic pressure as a buoyancy control. In adult *Nautilus*, the gas pressure in all chambers is always about 0.9 atmospheres, and the buoyancy control is effected by varying the liquid content of the last-formed chambers. The problem remained as to how the liquid was removed from these chambers, since the septa are impermeable and in the newest chambers the siphuncle is not in contact with most of the liquid when the animal is in its normal swimming position. Dr. Denton and Dr. Gilpin-Brown suggested that the explanation lay in a special wettable layer on the inside walls of the chambers. This layer functions in the manner of blotting paper, holding liquid which once touches it and transporting it to the living tissue of the siphuncle which then pumps it, by way of the circulation, out of the chambers. The liquid almost all disappears by about the fourth or fifth chamber behind the animal proper. Further work is needed on the pumping mechanism, since some cephalopods, such as *Spirula*, can certainly go deeper than 240 m, which is the limit set by a pump using simple osmosis.

A complementary paper on fossil cephalopods was given by Mr. C. W. Wright (London), who discussed present-day knowledge of ammonite ecology and systematics. He emphasized how great were the gaps in our knowledge of what was thought of as a 'well-known' group: even their attribution to the Tetrabranchiata could not be regarded as proved. Mr. Wright pointed out that modern cephalopods occupy a wide range of ecological niches and there was reason to think that the ammonites may have done the same. Although generally supposed to be free-swimming, buoyant forms, there were even examples of ammonites with asymmetrical sutures and siphuncles which may well have lain on one side on the bottom like flat-fish.

Recent evidence from the United States of assemblages of up to 400 individuals in isolated doggers suggests original gregarious associations, and Mr. Wright compared this with the breeding swarms of certain living cephalopods which migrate *en masse* and are very sensitive to temperature and salinity. Such a tendency for associations in 'schools' might help to explain the problem of the rapid evolution of the ammonites, since a mechanism was required for the isolation of parts of a population as an agent for speciation.

Mr. Wright contrasted the supposed two main stocks of Mesozoic ammonoids the smooth, thin-shelled, 'open-sea' forms such as *Phylloceras* and *Lytoceras*, and the ornamented, thick-shelled, 'inshore' forms which constitute the majority The slow evolution of the former might be due to random oceanic distributions, with little splitting up of the populations, while the more rapid evolution of the inshore forms might have been permitted by a combination of the diversity of habitats available in the inshore regions and the habit of associating in 'schools'

Rapid evolution and the repeated production of certain morphological types, such as the oxycones which turn up in many families, necessitate a fragmented classification Mr Wright concluded by pointing out that ammonite classifications, which can at best be only expressions of the present state of knowledge, must be regarded as experiments, to be tested against new information and material

A second important theme of the meeting was the relationship between the distribution of various marine animals in present-day seas and that in the fossil record Mr Norman Tebble (British Museum (Natural History)) described the distribution of certain present-day zooplankton, notably among the pteropods and polychætes, which particularly show a specificity to certain water masses He emphasized that temperature and salinity were among the principal controlling factors, with the greatest changes in distribution occurring at the surface hydrological boundaries, the Sub-Tropical Convergence, the Secondary Polar Front and the Antarctic Convergence He demonstrated a marked asymmetry in the distributions For example, among the pelagic polychætes of the Atlantic Ocean three were endemic to the Antarctic waters, sixteen extended from the Sub-Tropical Convergence to the Secondary Polar Front and two of these continued into the high boreal waters of the North Atlantic where there were no endemic species

In discussion, Dr W J Fry (London) remarked that the distribution of the pycnogonids, entirely benthonic, appeared, from available records, to parallel very closely the distribution of polychætes in oceanic waters, and he thought this similarity again underlined the caution necessary in ascribing particular types of aggregation to particular modes of life

Dr C. Edwards (Millport) also described modern distributions, with particular reference to the amphipod crustacea, notably '*Gammarus*' (sens lat), which have spread into brackish and fresh water Lake Baikal, the Caspian and the Black Sea were probably populated with representatives of this genus from the open sea during the Tertiary era They have numerous endemic species, but these are still morphologically close to marine forms On the other hand, the well-known freshwater shrimp *G pulex* has probably had a longer freshwater history The re-opening of the Black Sea to marine conditions has had the effect of driving the endemic species back into brackish water lagoons, deltas and river-mouths *Chaetogammarus tenellus* has ascended the Volga, the Danube and the canals of eastern Europe, and descended the Vistula to Gdansk becoming adapted *en route* to freshwater conditions, but will not descend into the brackish range at the mouth of the Vistula Perhaps competition with native brackish species in the Baltic limits its distribution *G locusta*, which is purely marine around the British Isles (where the brackish habitats are occupied by two other species), does go into the lower salinities of the Baltic, it is probably ill-adapted to fluctuating salinities but can adapt to constant low salinities

Dr Edwards suggested that it was a general rule that if species have become adapted to lower salinities they would not re-adapt themselves to fully marine conditions again if they could avoid doing so by entering brackish localities such as river-mouths and lagoons. After the paper there was some discussion about how this rule applied in the fossil record, particularly among the invertebrates Dr Edwards considered that an important factor was the longevity of marine environments compared with short-lived local freshwater habitats

A third paper which concerned itself with distribution through time as well as space was one by Dr F T Banner (British Petroleum Co , Ltd) on heterochronous homeomorphy in the Globigerinacea These wholly marine planktonic Foraminifera range in age from Lower Cretaceous to the present day and are found in all parts of the world Dr Banner produced numerous examples of Recent forms in which the tests are homeomorphic with those of distantly related Tertiary species Homeomorphy occurs particularly in species of *Globigerina* and *Globorotalia*, the geographical distribution of fossil forms was often parallel to that of their present homeomorphs, a relationship that may be of palæoecological significance Thus, unkeeled *Globorotalia* (*Turborotalia*) *scitula*, of widespread Recent occurrence, parallels the wide geographic distribution of fossil *G* (*T*) *fohsi barisanensis*, while heavily keeled *G.* (*G*) *tumida*, which is recorded only within 20° N and S of the equator, is equally similar to the Miocene *G* (*G*) *lobata robusta*, a form of limited geographic range within the tropics Bandy has suggested that keeled Globigerinacea may be indicative of tropical and warm areas in the Cretaceous as well as in the Cainozoic, and noted an apparent relationship between the distribution of keeled *Globotruncana* and palæotemperatures as estimated by Urey and others More recent discoveries of heavily keeled species of *Globotruncana* in the Maestrichtian of Denmark and Sweden do not, however, appear to support his hypothesis of such indications of a general climatic cooling at the end of the Cretaceous

Another example of homeomorphy was provided by the development of chamber-elongations in almost all groups of the Globigerinacea independently Eocene *Hantkenina* and Cretaceous *Schackoina*, both possessing superficially similar narrow spine-like processes, had a wide geographical distribution, but other homeomorphic groups, such as the clavate *Hastigerinella* (Recent) and *Schackoina* (Cretaceous), appear to have a restricted geographic distribution Generalizations, although hazardous, might be made to suggest that, relative to a morphologically simple and geographically widespread ancestral stock, the more elaborate the test, the more restricted became the habitat of the morphologically most advanced species

Combining his investigations of both ancient and modern brachiopods, Dr M J S Rudwick (Cambridge) discussed the development of protective devices in various articulate groups As with the Globigerinacea, Dr Rudwick was able to produce numerous examples of deceptively close convergence He quoted the classic case of the Middle Triassic spiriferoid *Tetractinella* and the Upper Jurassic terebratuloid *Cheirothyris* In this case he suggested that the prominent projections on the shells served to carry the mantle margin outwards as an 'early warning' device This fitted in with observations on the extreme tactile sensitivity of the mantle edge in modern brachiopods Similarly, the hollow spines of such rhynchonelloid genera as *Acanthothiris* might have been another early warning system

Dr Rudwick then described his extension of the pre-war work of Herta Schmidt on the zigzag margins which are present in many brachiopods, and the probability of their having functioned as filters to prevent the entry of over-large grains into the shell These zigzag margins developed in several different ways during ontogeny, suggesting that they were evolved independently in different groups One variety, which is associated with a distinctive pattern of shell ornament, was itself apparently evolved three times, in the Devonian genus *Nayunella* (= *Yunnanella* auctt), the Jurassic *Rimirhynchia* and some species of the Cretaceous *Cyclothyris* All varieties of zigzag margins disappeared at the end of the Mesozoic and are unknown in Cainozoic or living brachiopods Dr Rudwick mentioned, however, that a few living species possess another kind of protective device the edge of the shell is 'guarded' by rows of sensitive setæ. Grooves along the margins of many fossil brachiopods probably indicate the positions of setæ which had the same function.

The final morning of the meeting was devoted to papers and discussion of ancient and modern reefs. The first paper in this session was by Dr. S. A. Wainwright (California) on modern reef coral associations. He started by emphasizing the need for more quantitative field studies of associations. He discussed the various organisms which directly affect coral morphology, such as boring green algae, symbiotic zooxanthellae and predators among the polychætes, gastropods, asteroids, cirripedes, crabs and fishes. One particularly good example was the parrot-fish which eats living coral on the open parts of the reef, and Dr. Wainwright suggested that palæontologists should look out for such features as the teeth marks of fish and gastropod scars (which are often specifically determinable) in fossil coral reefs.

Dr. Wainwright next considered the distribution of corals on the reefs, taking Fanning Island, in the Central Pacific, as an example. He showed graphically the increase in number of species and growth-rate from the reef flat to the edge of the reef slope, at about 10 fathoms, though with a marked break over the reef ridge, where only algae survive in the heavy surf. Normally, in areas of heavy surf many corals are broken and rolled about, and the consequent abrasion provides many a habitat for boring sponges, gastropods and, of course, new corals. Coral fragments and even blocks up to a ton or so are carried up the reef and thrown on to the beach by wave action. On the slope immediately below the ridge there are only massive encrusting corals, but these pass down into the more fragile branching types at the bottom of the slope.

Dr. Wainwright ended by appealing to biologists to examine reefs and their associations in even greater detail so that not only would the dynamics of reef-building and reef ecology be more clearly understood but also the sort of information available to the palæontologists would be greatly enlarged. From the palæontologists' point of view, what is desired is more information about coral associations in present-day seas, the biological role of their association and the effects of the associations on the growth pattern of the coral skeleton. The weaknesses inherent in the act of extrapolating from living to extinct organisms are greatly reduced when one deals with species-specific associations the manifestations of which are equally specific, or associations which are 'area specific' in relation to the whole coral reef.

Mr. G. F. Elliott (Iraq Petroleum Co.) turned to the other important constituent of reefs in his paper on past and present calcareous algae. He pointed out that calcifying algae at the present day are distributed among many groups and that some fossil ones are similar to living forms which are not calcified. Their maximum development is found in warm waters and they show a great variety of form. There are the delicately beaded types with light calcification, characteristic of the green algae; there are the thread-like masses within the sediment of the blue-green algae; and there are the massive, heavily calcified structures of the red algae. The fronded forms all occur in sheltered waters. The very common green alga *Halimeda*, for example, is very abundant in lagoons and also occurs (though less commonly) on the lower part of the reef slopes, down to considerable depths. On the other hand, the massive red algae, for example *Lithothamnium*, are particularly important on the exposed parts of modern reefs. These algae also perform an even more important function in binding together reef debris. Their tremendous growth-rate makes up for breakage by the surf, and Dr. Wainwright, in discussion, added that it has been estimated that algae extract calcium carbonate from the sea-water up to 100 times faster than corals.

In the fossil record, Mr. Elliott pointed out, an important consideration is the rapid diagenesis of algal calcifications. This is partly due to the fact that the carbonate is laid down as fine particles (not in laminæ, as in other calcareous organisms) and also due to the high proportion (up to 18 per cent) of magnesium carbonate sometimes present, which leads readily to the process of dolomitization: many beds of dolomite are probably algal in origin.

Mr. Elliott then summarized the fossil record of calcareous algae from Precambrian times onwards. He directed particular attention to certain points, notably the importance of the blue-green algae in the early part of the record, the rarity of algae in the Devonian reefs and the great importance of algae in Carboniferous and Permian reefs as compared with the Mesozoic. The coralline algae appeared in the Upper Cretaceous and came to dominate the reef environment in Tertiary times.

Prof. M. Lecompte (Brussels) discussed the building organisms of the Devonian reefs of Belgium, their ecological characteristics and bathymetrical distribution. He confirmed Mr. Elliott's observations on the rarity of algae in Devonian reefs, apart from the problematical *Stromatactis*, but he demonstrated clearly the regular succession of forms which are seen repeatedly in both bioherms and biostromes, and which can be related to the depth and turbulence of the water. He emphasized the long-term nature and wide extent of reefs in Belgium and adjacent areas, clearly the result of a rhythmic epeirogenic control, which repeatedly brought the sea-floor to the right depth for reef growth. The reef periods alternate with periods of shale deposition, and each time a succession can be traced through: (1) a 'deep-water' zone; (2) a 'quiescent' zone; (3) an 'infra-turbulent' zone; (4) a 'sub-turbulent' zone; (5) a 'turbulent' zone. Each of these is characterized by a particular suite of fossils. The deepest zone shows a dominance of brachiopods, notably stunted variants of forms which occur also in other bathymetric zones. These are followed upwards by the appearance of first solitary and then massive corals. Tabulate forms, such as *Alveolites* and *Thamnopora*, are the main builders in the 'infra-turbulent' zone, but several of them apparently could not live in the rougher water. Many other forms also appear, such as bryozoans and sponges. Lamellar stromatoporoids come in very strongly in the 'sub-turbulent' zone and are replaced by massive stromatoporoids in the 'turbulent'. Stromatoporoids were apparently excluded from muddy environments, but the pure limestones of the 'turbulent' zone are largely composed of these organisms, associated with a wide variety of other groups, such as corals, brachiopods, crinoids (which are usually underestimated) and *Stromatactis*. The last-named was probably very important, but is usually not preserved.

The final paper of the meeting was by Dr. W. S. McKerrow (Oxford) on some local Jurassic coral reefs. This was an introduction to an excursion that was held in the afternoon. Dr. McKerrow described two horizons at which corals were found in life position. In the Upper Oxfordian 'Corallian' beds (Upper Jurassic) branching corals were to be seen thus near Faringdon, Berkshire. The reef rock around Oxford, known as the Coral Rag, is contemporaneous with the detrital Wheatley Limestone which is composed of reef debris. The other coral occurrence was in the Great Oolite Series (Middle Jurassic) at Witney, Oxfordshire. The corals in these earlier beds have been attributed to five different genera, belonging, in the latest classification, to three different sub-orders. Dr. McKerrow showed by means of actual specimens that there were transitions between the different types. The simple *Montlivaltia* clearly passes into the branching *Thecosmilia*, and among compound massive types *Isastraea* (with walls between the corallites) passes into *Thamnasteria* (in which the walls have disappeared), and the latter (with solid septa) passes into *Microsolena* (with perforate septa). These passages could be seen in the same colonies, with the septa in direct continuation. It appeared that the taxonomy of these forms was based (at least in this case) on phenotypic rather than genotypic characters

The excursion in the afternoon, led by Dr McKerrow and Dr H G Reading, visited first an exposure of the Great Oolite at Crawley Road Quarry, Witney, where members saw a Bradford Fossil Bed reef in the Forest Marble The presence in this reef of remains of all animal groups except cephalopods suggests a shallow lagoon in which the water was too turbulent for cephalopods The second quarry visited showed a 'Corallian' reef at Shellingford Cross Roads Quarry, near Faringdon, where members saw patches of massive corals in early layers give way to mainly loosely-branching corals higher up, suggesting an increase in the depth of the water at this particular locality with time The detrital Wheatley Limestone in this quarry was seen below the Coral Rag

In the course of the symposium special thanks were expressed to Prof J W S Pringle for entertaining the meeting at Oxford

FOREST RESEARCH

MANY factors influence the growth of forest trees, and these factors cover a particularly wide range when the practice of forestry is largely concerned with afforestation and the use of exotic trees Thus it is easy to understand why forest research in Britain is so comprehensive This is certainly shown by the numerous projects described in the annual report of the Forestry Commission for the year ending March 1962[*]

Where so much dependence is placed on seed supply for ensuring the large planting programme provenance and genetics are very important Not only are vigorous trees wanted but also especial attention is being directed to those provenances which show resistance to frost So that the forester may know where to obtain tree seed in Britain of the best of the existing varieties and cultivars, the *Register of Seed Sources* has been brought up to date and it now contains 535 classified seed sources totalling 8,833 acres Associated with this has been the work of converting the best seed sources into seed stands and thus improving the genetic quality of seed collected in Britain

Much attention is being directed to the study of soil moisture Deep peat remains a problem with its poor drainage, the physical instability of the trees, the difficulties of timber extraction and not enough being known about the water and nutrient régimes of the trees There is another drainage problem on heavy clay soils, but some hope is seen in improved types of mechanical drain diggers

Exposure is a limiting factor to afforestation on many sites in Britain, and it is not easy of assessment However, an inexpensive technique has been developed by using the rate of tatter of standard cotton flags set up for a period on the sites being studied An account of this method is to be published soon Wind damage is being examined from various aspects, and one project uses a wind tunnel to determine the relationship between wind velocity and the forces acting on a tree Another project utilizes the 'tree-pulling' technique to test the effect of direction of pull on tree resistance Both series of experiments should bring out useful information, but they do not seem to take into consideration that trees in a forest are often subjected to gusts and turbulence and not to a steady force of wind

The annual report for the New Zealand Forest Service[†], covering the period January 1–December 31, 1962, shows an economic flavour Emphasis is laid on the quality of the end-product so that utilization will be the most profitable possible Hitherto, New Zealand's high-grade timber has largely come from its indigenous forests, but these resources are now approaching exhaustion The tools at the disposal of the sylviculturist in order to obtain a better proportion of good-grade timber from the exotic forests are pruning and thinning and, therefore, present investigations are attempting to relate pruning and its effect on grade enhancement and the relationship between green crown depth and the density of the stand However, the importance of protection forestry is not being forgotten More watershed surveys have been carried out, and some reveal conditions which are rather disturbing Active erosion and the resulting outpourings of detritus into streams may be largely due to red deer, goats and opossums destroying the protective vegetation cover In some of the more accessible areas, hunters appear to exert sufficient control on the deer numbers and so the vegetation cover is in reasonable condition to give adequate protection against soil erosion

RETURN OF THE NENE TO HAWAII

FROM the beginning of the Wildfowl Trust's attempts to rear the Hawaiian geese, *Branta sandvicensis*, in 1950, it had been hoped that it would become possible to return the Hawaii geese reared at Slimbridge The growth of the stock has been slow and some of the birds raised have been dispersed to other collections in Europe and North America in order to increase the chance of maintaining and developing flourishing stocks in captivity By 1960, however, enough geese had been reared to allow the return of some of the nenes to Hawaii It was not until the summer of 1962 that this somewhat complicated and expensive operation could actually be carried out[*]

The Division of Fish and Game, Department of Land and Natural Resources of the State of Hawaii, proposed that the Slimbridge-reared geese should be used in an attempt to re-establish the species on the Island of Maui, where it had been extinct for many years A survey of the existing habitat on Maui in June 1960 showed that there were 9,000 acres of excellent nene habitat and a further 30,000 acres likely to be of some value A release site was selected near Paliku within the Haleakala National Park There were strong reasons for this choice the area at the upper end of the Kampo Gap provides excellent nene habitat with food throughout the year, it is remote, ensuring a minimum of disturbance to the birds in the release pen, suitable accommodation exists for the people needed to care for the birds

In June 1962 thirty geese were despatched by air from Slimbridge to New York They were taken to the U S Federal Quarantine Station at Clinton, New Jersey, where they were held for 21 days They were then sent on by air freight to Honolulu There they were kept in the Zoo for three days to recover from the journey and were

given individually distinctive plastic leg bands On the twenty-sixth day they travelled by air to Kahului, on Maui

The Slimbridge birds consisted of 10 juveniles, 7 one year old, 10 two years old, 2 three years old and 1 four years old 17 were females and 13 males At Kahului they were joined by five juvenile females reared by the State's Pohakuloa propagation project on Hawaii The 35 birds were put in light-weight cardboard boxes and taken by lorry up to the rim of Haleakala Crater Here the boxes were loaded on pack boards and were carried on the backs of 23 Boy Scout volunteers 8 5 miles down into the Crater and across to the release pen at Paliku on the other side

The release pen at Paliku encloses about an acre of good grass, on the edge of an ancient 'aa' lava flow The geese were released in the late afternoon of July 26 As they were removed from the boxes, their clipped primaries were extracted so that new feathers would start to grow immediately The birds were given constant care and supplied with native berries and scratch feed daily They were also treated for coccidiosis and cæcal worms—these parasites having been detected in the fæcal droppings of the flock There was much pecking and other signs of social adjustment for a week or so, but the birds soon settled down

The geese began making short flights within the pen early in September The first flights out of the pen were seen on September 12, two Hawaiian-reared birds being the pioneers The first Slimbridge bird did not fly out until September 17 By the end of the month, 27 out of the 35 were flying a few hundred yards out of the pen, returning at dusk The Hawaiian and English birds, though remaining in distinct flocks within the pen, mixed very well outside it

Earlier experience with four separate releases, of 87 birds in all, on the Island of Hawaii, made with similar release pens, has shown that the geese will generally remain in the vicinity of the pen for several months It is planned to make annual releases of nenes from the same pen in Haleakala Crater for at least two more years, a total of 100 birds being the aim

DAMAGE TO LIVESTOCK FROM RADIOACTIVE FALL-OUT

IN the event of nuclear war, one major problem for civil defence authorities would be the availability and maintenance of food supplies One aspect of this problem, the effect of fall-out on domestic animals, is considered in a report, entitled, *Damage to Livestock from Radioactive Fallout in Event of Nuclear War*, prepared by the Subcommittee on Livestock Damage of the Advisory Committee on Civil Defence, National Academy of Sciences—National Research Council, Washington*

The object of the report is to present estimates of the biological effects of various levels of radiation exposure These estimates could be used by civil defence planners, whose responsibility would be, first, to feed a population during emergency conditions immediately following a nuclear attack, secondly, to sustain a population during the subsequent recovery period, and, thirdly, to ensure an adequate maintenance of animal populations No attempt is made to present maximum permissible levels of exposure, since this concept is considered irrelevant under conditions of national emergency where famine and other hazards would far exceed those normally found in peacetime The report therefore deals mainly with the lethal effects of radiations received from external sources or from radioisotopes within, or on, the bodies of animals On the effect of external radiation, animals investigated include cattle, pigs and poultry, and details are given of the clinical responses of these animals following radiation exposure Estimates are also presented of the mortality and possible utilization of food animals at different times after brief exposures to various doses of radiation For mammals, it is estimated that a dose of 350 rads would have only a negligible effect on salvageability, following a dose of 750 rads, most animals could be salvaged during the first three days after exposure, but by the fourteenth day all animals would be unfit for use Estimates for poultry suggest that these animals are able to withstand slightly higher radiation doses than mammals

The ingestion of radioisotopes may damage the health of food animals, but may also render them unfit for human use because of the radioactive contamination. The report suggests that contamination should not be significant immediately after a nuclear attack but may become serious if food animals receive protracted exposure to contamination This factor might be more important for isotopes like cæsium-137, with a general distribution in the body, than for iodine-131 and strontium-90 which are concentrated in specific sites Iodine-131 in milk, however, may represent a hazard, particularly to young children An assessment of the suitability of contaminated animals for human consumption would require knowledge of the amount and distribution of fall-out The report describes formulæ which could be used to estimate the probable human hazard on the basis of radioactive contamination of the food intake of animals, it also suggests the use of certain foods, such as poultry, eggs and some marine animals, which would not be highly contaminated

On the problem of stock maintenance, the report considers that radiation exposure would not be seriously harmful Data from a wide variety of adult animals showed no effect on fecundity from radiation exposures of 400 rads One gap in the data, however, concerns the radiation sensitivity of young animals Irradiation of pregnant animals produces abnormalities in the fœtus, but this would be of minor importance in stock maintenance Similarly, gene mutations would be unimportant, particularly in view of the high level of selection normal to animal husbandry

Final chapters in the report contain recommendations on methods for handling animals which have been exposed to fall-out and suggestions on areas of investigations in which research is urgently needed A series of appendixes present the basis on which estimates are made throughout the report and a comprehensive list of references is also included

MUCUS IN INVERTEBRATES

A GROUP of scientists interested in investigations on "Mucus in Invertebrates" met on August 27, 1963, in Washington, D C, during the sixteenth International Congress of Zoology The session was organized for the Division of Invertebrate Zoology of the American Society of Zoologists by Dr Sophie Jakowska, Food and Drug Research Laboratories, Inc, Maspeth, New York

Twelve speakers, representing Australia, Brazil, Canada, Denmark, Sweden and the United States, discussed various aspects of slimy secretions of lower animals The subjects discussed by the speakers included: adhering surfaces in *Hydra* and starfish (Dr. Chaet, American University, Washington, D.C.), mucus-like materials involved in eggshell formation of trematodes (Dr. Clegg, Australian National University, Canberra), mucus of the giant slug, *Ariolimax columbianus* (Dr. Taylor, Albert Einstein Medical Center, Philadelphia), regeneration of mucus-producing cells in the slug (Dr. Arcadi, Whittier College, California), mucus gland in the octopus (Drs. Gennaro and Lorincz, University of Florida), mucous secretions in ophiuroids (Dr. Fontaine, Victoria University, British Columbia), and in crustaceans (Dr. Dahl, University of Lund, Sweden, and Dr. Steeves, University of Alabama). Mucous substances of protochordates were described by Dr. Norrevang (University of Copenhagen), Dr. Olsson (University of Stockholm) and Dr. Sawaya (University of São Paulo, Brazil). The papers listed on the programme which were not presented included investigations on turbellarians (Dr. Pedersen, University of Copenhagen), on effects of photoperiod on mucus secretions of gastropods (Dr. Segal, San Fernando Valley College, California), and mucopolysaccharides in *Molgula* (Mrs. Bonnelly deCalventi, University of Santo Domingo, Dominican Republic).

The participants emphasized the great variety of structures in which mucoid substances originate, and their role under normal and experimental conditions. Opinions were expressed that, although there is relatively little information on the chemistry of such materials from invertebrates, it is to be expected that they probably differ in chemical composition from each other, and from the typical salivary secretions of man and mammals which so far have received considerable attention. The ultrastructure of mucus-secreting surfaces was demonstrated by several speakers.

The chairman urged the participants to exploit their familiarity with the widest variety of mucus-secreting organisms as natural working models of normal and abnormal conditions which cannot be examined with equal ease in higher animals. These investigations may shed further light on the physico-chemical properties of pathological mucous secretions, for example, such as those occurring in cystic fibrosis.

During the discussion, a number of speakers remarked on the apparently high concentration of iodides in marine invertebrates which normally secrete copious mucus, as suggested by the characteristic odour. Dr. Anna M. Bidder (University of Cambridge) pointed out the value of excised octopus gut for *in vitro* investigations on mucus secretion. Dr. Fontaine (Victoria University, British Columbia) mentioned a species of starfish, commonly found along the Pacific Coast, and valuable for the abundant mucus they secrete and collect in a pouch-like structure. Other living systems of interest (for example, hemichordate proboscis) were suggested as models for investigating rheological properties of mucus. The utility of common invertebrates noted for their slimy secretions (slugs, snails) was also stressed.

Since this informal symposium represented only a session of related papers during the Congress of Zoology, full manuscripts are not published as part of the Congress *Proceedings*. The chairman was, therefore, instructed to seek the most suitable means of publication in form of collected papers on mucus in invertebrates. Additional papers and brief communications have been pledged by other authors. The papers have been submitted to the New York Academy of Sciences for publication in the form of *Annals of the New York Academy of Sciences*. A previous monograph dealing with mucous secretions, including a few papers on mucus in invertebrates, appeared in the *Annals* in March 1963.

It is hoped that publicizing this meeting and the forthcoming publication will encourage others to work in this important field. A future meeting is planned for 1965 or 1966. Further information can be obtained from Dr. Sophie Jakowska, Food and Drug Research Laboratories, Inc., Maspeth, New York.

NATURAL OCCURRENCE OF AMINO-ACIDS IN DOLOMITIC LIMESTONES CONTAINING ALGAL GROWTHS

By Dr. J. S. HARINGTON*

Pneumoconiosis Research Unit, South African Council for Scientific and Industrial Research, Johannesburg

AND

Dr. P. D. TOENS

Department of Geology, West Rand Consolidated Mines, Ltd., Transvaal

THE detection of fluorescent oils containing polycyclic aromatic hydrocarbons and amino-acids in crocidolite and amosite asbestos, but not in chrysotile, has been reported by Harington[1,2] and an organic origin for these materials has been suggested[3].

This article concerns the detection of amino-acids and hydrocarbons in dolomitic limestones underlying the Pretoria Series in which the crocidolite asbestos horizons are present in the north-western Cape Province, South Africa.

The Dolomite Series is composed almost entirely of carbonate rocks[4]. It is about 10,000 ft. thick in the north-western Cape and 4,000–7,000 ft. in the western Transvaal[4], and has an estimated age of about 2,000 million years[5].

Recent investigations[4] have postulated that deposition of the Dolomite Series occurred under warm, shallow and saline conditions. To allow carbonates to precipitate, the *p*H of the water must have been about 8 (± 0·5). Reducing conditions would also have been required for the preservation of organic matter and the formation of pyrite. Various types of algae, of which fossil remains have been found, probably flourished in these quiet conditions, forming a skin over the surface of the sediments.

The siliceous rocks of the overlying Pretoria Series must have been deposited under mildly oxidizing conditions to permit the formation of iron oxides. These conditions would probably not have enabled organic growths to be preserved within the rock, although the detection of amino-acids[2] does suggest that organisms of some sort were present.

*Cyclo*hexane and ethanolic extractions of three samples of pulverized, primary, dolomitic limestones were carried out by methods described earlier[1,2]. Precautions were taken to avoid contamination of the rocks before and during analysis.

Specimen 1: *Dolomitic limestone containing stromatolites* (carbon content 0·15 per cent). These algal growths exhibit distinct and rather elaborate branching, and closely resemble the algal heads and domes which are forming in the Great Bahama Bank at the present time[6]. The zones in which these structures are present vary in

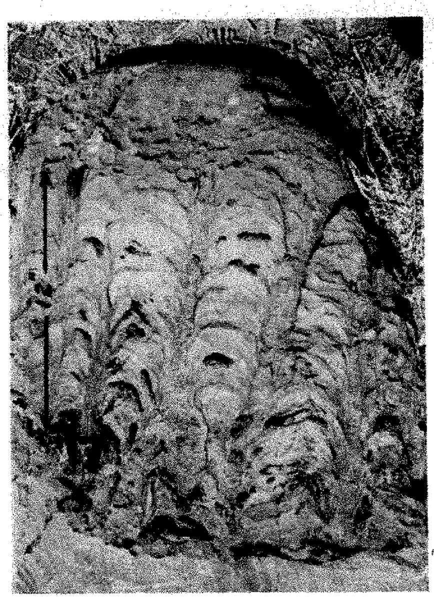

Fig. 1. Dolomitic limestone containing algal growths (from Danielskuil, N.W. Cape, South Africa)

thickness from 6 in. to 10 ft. or more. The growths consist of a number of superimposed cones which are composed of fine algal filaments (Fig. 1).

Specimen 2: *Algal limestone underlying the Pretoria Series* (carbon content 0·20 per cent). About 100 ft. of impure algal limestone are present immediately below the Pretoria Series. The rocks are dark grey and have a distinctly fetid odour on fresh fracture (? hydrogen sulphide). Extremely contorted banding is present, and is caused by the wavy nature of the algal filaments preserved in the rock. Minute specks of pyrite are abundant and occur within the algal banding.

Specimen 3: *Shaly limestone from Silverstreams.* This specimen was derived from a narrow band of fetid, dark, shaly limestone lying below a layer of chert in a quarry. Extremely contorted shaly bands are visible in thin section and are probably due to movement which has forced the shale into cracks and along bedding-planes in the fine-grained limestone. Within the shale numerous crystals show zonal and patchy distribution of calcite and dolomite. Algal banding was not identified unequivocally, but was suspected of being present in some samples.

The results of analyses for amino-acids obtained by a semi-quantitative, paper chromatographic method are given in Table 1. Values for crocidolite asbestos, obtained earlier[2], are included for comparison.

Table 1. AMINO-ACID COMPOSITION OF ORGANIC EXTRACTS OF DOLOMITIC LIMESTONES CONTAINING ALGAL GROWTHS (μg/1,000 G ROCK)

Amino-acid	Crocidolite fibre (ref. 2)	(1) Stromatolite	(2) Algal limestone	(3) Shaly limestone
Serine	950	3·3	2·5	2·0
α-Alanine	380	13·3	3·8	4·0
Glycine	350	3·3	1·3	2·0
Aspartic acid	240	—	0·6	—
Threonine	170	—	0·6	2·0
Leucine	140	—	0·6	20·0
Isoleucine	140	—	—	20·0
Valine	140	—	—	—
Phenylalanine	100	—	0·6	4·0
Glutamic acid	70	1·5	0·6	2·0

Analyses of the three specimens for oils and 3 : 4-benzpyrene[1] showed that both were present in No. 2, and neither in No. 1 nor No. 3. In all three cases, the yields after *cyclo*hexane and ethanolic extraction were, in general, insignificant (mg/100 g dust): 0·3 and 7·4; 0·4 and 1·8; 0·1 and 3·2, for samples 1, 2 and 3 respectively. A sample of algal dolomite from the western Transvaal (2,226 g), investigated because it contained very well-preserved algal growths, and because the overlying Pretoria Series does not contain asbestos in this area (Klerksdorp), gave no detectable yields after *cyclo*hexane and ethanolic extractions and neither 3 : 4-benzpyrene nor amino-acids was detected by analysis. Such negative results serve as useful control checks against accidental contamination of the samples before and during analysis.

The detection of amino-acids in carbonate rocks of the Dolomite Series, together with the presence of algal structures, suggests that organic processes were active during the deposition of these rocks about 2,000 million years ago, and that the Dolomite Series has undergone very little metamorphism since then.

We thank Dr. J. J. le R. Cilliers for advice, Mr. Paul Baily for performing the analyses and Miss Marianne Smith for assistance.

MAGNETO-HYDRODYNAMIC GENERATION AND NUCLEAR REACTORS

By J. K. WRIGHT

Fundamental Studies Section, Central Electricity Research Laboratories, Leatherhead, Surrey

THE problems of the design of both high-temperature nuclear reactors and magneto-hydrodynamic (MHD) generators are being actively investigated by large research teams in various parts of the world. The purpose of this article is to discuss some of the problems of using a MHD generator in conjunction with a nuclear reactor.

The early commercial nuclear reactors have low gas temperatures and consequently the electricity is generated at low thermodynamic efficiencies. For example, the Berkeley Nuclear Power Station, with a reactor gas exit temperature of 345° C, has an overall thermodynamic efficiency of only 24·6 per cent, whereas the Dungeness reactors when built will have an exit gas temperature of 410° C resulting in an overall thermodynamic efficiency of 32·9 per cent. Both these systems are graphite moderated gas-cooled reactors with magnox cans. The purpose of more advanced designs is to increase the operating temperature and, consequently, thermodynamic efficiency. Advanced gas-cooled reactors will operate with reactor gas temperatures in the region of 625° C, and the *Dragon* reactor is designed to have an exit gas temperature of 800° C, which might be extended to 1,000° C with future developments.

More advanced types using ceramic fuel elements might be developed to operate at still higher temperatures. In this range the use of steam as a thermodynamic working fluid becomes less favourable and other systems would be used. One method of converting the heat energy in the reactor coolant gas into electrical energy is to use an MHD generator.

As well as effort being placed into raising the operating temperature of nuclear reactors, methods of lowering the minimum operating temperature of an MHD generator have been suggested. This minimum temperature of the working fluid is determined by the need to obtain adequate electrical conductivity. Using a favourable working medium, such as helium, seeded with about 1 per cent of cæsium, and relying on the temperature of the working fluid to produce the required ionization, minimum temperatures of the order of 1,700° C are obtained

This minimum temperature may possibly be reduced by some non-equilibrium ionization technique Proposed methods include external ionization by an auxiliary discharge or by injecting electrons and relying on the low recombination cross-sections of the inert gases to maintain a high degree of ionization and therefore electrical conductivity Another proposed method is to use the induced MHD currents to break down partially the gas and thereby increase the electrical conductivity Since this works essentially by preferentially heating the electrons in the gas, the method is known as 'elevated electron temperature' This method has considerable potential although it has yet to be proved experimentally in an actual MHD generator It is also not yet known at how low a gas temperature it will work

A crucial question at this time is whether it is worth attempting to develop high-temperature reactors and the associated low-temperature MHD plant In the following example it is shown that an MHD generator-reactor system operating at a very high temperature is not necessarily more efficient than an equivalent gas turbine-reactor system operating at a somewhat lower temperature

Consider a nuclear reactor with an exit gas temperature T_1 °K feeding an MHD generator or gas turbine of stage efficiency η_1 and having an exit gas temperature T_2 °K The gas is then cooled in a heat exchanger to a temperature T_3 °K and compressed from P_0 to P_1 in an isothermal compressor of efficiency η_2 before being heated to a temperature T_4 °K by the heat extracted from the previous heat exchanger Fig 1 shows the scheme

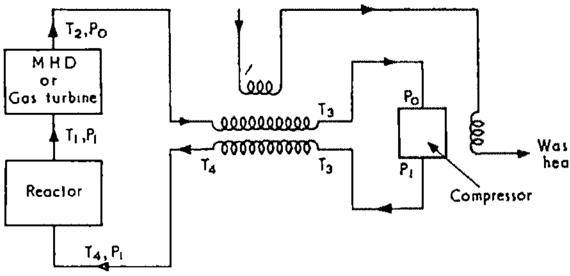

Fig 1

Pressure drops across the reactor and heat exchangers are ignored and it is assumed the circulating gas has a constant specific heat at constant pressure C_p

Then for unit mass of gas

Heat gained in reactor = $C_p(T_1 - T_4)$

MHD or gas turbine output = $C_p(T_1 - T_2)$

Work done in isothermal compressor =

$$\frac{\gamma - 1}{\gamma} \frac{C_p T_3}{\eta_2} \ln P_1/P_0 = \frac{C_p T_3}{\eta_1 \eta_2} \ln T_1/T_2$$

Since the pressure ratio across the gas turbine or MHD duct is

$$\frac{P_1}{P_0} = \left(\frac{T_1}{T_2}\right)^{\gamma/\eta_1(\gamma - 1)}$$

Hence the cycle efficiency is

$$\frac{T_1 - T_2 - \dfrac{T_3}{\eta_1 \eta_2} \ln \dfrac{T_1}{T_2}}{T_1 - T_4}$$

For the sake of illustration, values have been chosen of $T_3 = 350°$ K (77° C) and $T_4 = T_2 - 200°$ representing the drop across the heat exchanger and any losses These figures are typical but are not intended to be optimized in any way

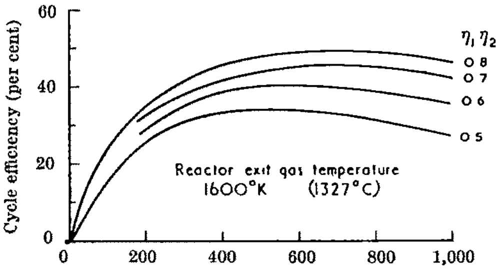

Fig 2

Fig 2 shows the way the cycle efficiency varies with MHD or gas turbine exit temperature for a particular reactor exit gas temperature of 1,600° K Notice how the efficiency decreases with the product of turbine and compressor efficiencies $\eta_1\eta_2$ Efficiencies approaching 90 per cent are typical for gas turbines and compressors, so a value for $\eta_1\eta_2$ of 0 8 might be typical for a gas turbine generator system Since there are no experimental data on the performance of MHD generators using non-thermal ionization it is difficult to assess the turbine efficiencies that may be obtained in practice, but values of $\eta_1\eta_2$ of 0 6 are probably realistic Notice also the significant temperature drop across the MHD duct for optimum working

Fig 3 is a diagram of system efficiency against reactor gas temperature The upper curve shows the best performance of a gas turbine system with $\eta_1\eta_2 = 0\ 8$ The middle curve is for the optimum efficiency of an MHD generator with $\eta_1\eta_2 = 0\ 6$ The lower curve shows the performance of an MHD system when the MHD exit stagnation temperature is restricted to 1,200° K (929° C) This may correspond to a temperature of the flowing gas at the exit of the duct as low as 800° C It is not known at how low a temperature the non-thermal ionization processes will operate, but the limit of 800° C (which may be optimistic) has a pronounced effect on cycle efficiency at reactor gas temperatures below about 1,400° C

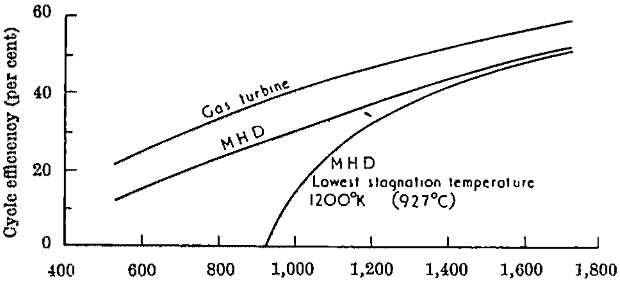

Fig 3

The foregoing example is, of course, a particular, simple and idealized thermodynamic cycle However, the conclusions that it is necessary to work with an MHD exit gas temperature well below the reactor exit temperature and that gains in MHD 'turbine efficiency' can be as important as reductions in minimum working temperature are probably generally valid In particular, it should be noted that gas turbines which should be capable of operating at reactor exit gas temperatures of the order of 1,000° C in a helium atmosphere may lead to a cycle as efficient as one using MHD with a reactor exit gas temperature of the order of 1,300° C A much more detailed investigation of MHD performance using non-equilibrium ionization and of reactor performance and costs at various temperatures must be made before any final conclusions can be drawn about the usefulness of MHD for nuclear reactors

LOW-LEVEL ASSAY OF IODINE-131 IN BIOCHEMICAL RESEARCH

By Dr C. F. BARNABY and Dr L. G. PLASKETT

Medical Research Council Department of Clinical Research, University College Hospital Medical School, London, and Department of Biochemistry, University of Edinburgh

IODINE-131 ($Z = 53$, $N = 78$) was first used as a biological tracer by Hamilton and Soley in 1939 (ref. 1). Iodine-131 can be cheaply produced by the reaction ^{130}Te (n, γ) ^{131}Te, ^{131}Te β/25 min ^{131}I, and is also a fission product. Because of this, and its convenient half-life (8.05 days), it has become widely used. Furthermore, the energies of its β- and γ-radiations are such that, with sources of high or medium activity, assay is a relatively simple matter, requiring no very specialized equipment.

The daughter product of the decay of iodine-131 is stable xenon-131, the present accepted decay scheme is shown in Fig. 1.

In addition to making iodine-131 the isotope of choice in the examination of both intrathyroidal and peripheral iodine metabolism, these properties have induced many workers to use it for examining systems in which iodine is not normally involved. Fat[2], protein[3] and carbohydrate[4] labelled with iodine-131 have found a place in biochemical research, and the isotope has also been utilized in the double isotope derivative technique for the analysis of amino-acid mixtures[5]. In spite of the ease with which iodine-131 may be assayed, some of these applications involve low-level counting problems. It is the purpose of this communication to examine the nature of these problems as they occur in the examination of iodine metabolism and to suggest ways in which they can best be solved. Details are provided of a counting system which has proved its value in the scanning of low-activity paper chromatograms, and we discuss the results which have been obtained in analysing the iodine compounds of extrathyroidal tissues.

Need for low-level counting in experiments involving administration of ^{131}*I-iodide.* Experiments are commonly designed in which radioactive iodide is administered to an experimental animal or human subject. Its fate is then followed by external counting of parts of the body, by assaying the radioactivity of the excretions and body fluids, or, after death, by determining the distribution of radioactivity among the organs and tissues. It is also usually desirable to investigate the chemical nature of the labelled material in the tissues and body fluids, and this necessitates fractionation procedures. It is the introduction of fractionation which most frequently poses the low-level counting problems. The fractionation technique which has achieved greatest success for the separation of iodinated compounds is paper chromatography[6,7], in which the sample size is always very small.

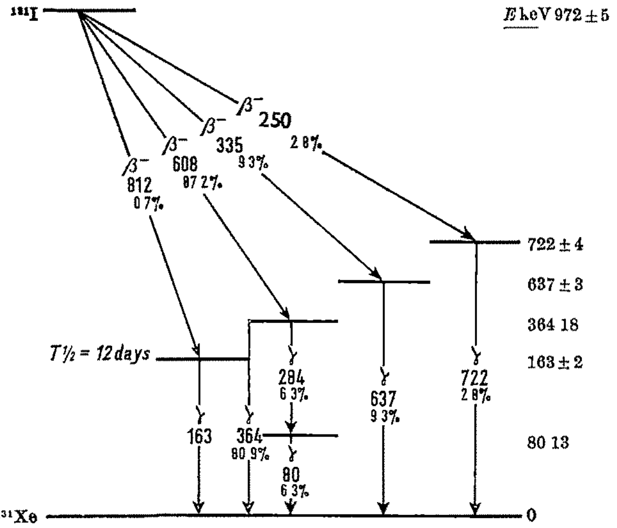

Fig. 1. Decay scheme of iodine-131

Analysis of thyroid. In the analysis of thyroid tissue the problems of low-level counting are least apparent. The thyroid gland concentrates injected ^{131}I-iodide, and therefore, in equilibration investigations such as those of Pitt-Rivers and Rall[8], there is usually no problem in estimating the radioactivity of even very minor components of thyroid tissue, autoradiography of paper chromatograms, although relatively insensitive, is quite applicable. The same is true of the analysis of thyroid tissue several hours or several days following a single dose of iodine-131, because uptake is high and the iodine pools of the thyroid are approaching isotopic equilibrium. One situation in which low-level counting becomes important is in kinetic experiments in which it is necessary to examine the labelled compounds of the thyroid gland a few minutes after a dose of iodine-131. In this situation thyroid uptake is usually a fraction of 1 per cent of the dose, and the radioactivity of a minor component with slow turnover, such as triiodothyronine, may be a small fraction of 0.1 per cent of the radioactivity of the gland[9]. Either low-level counting must be used or large doses of iodine-131 must be used which may constitute a hazard to the experimenter.

Analysis of peripheral tissues. A completely different situation exists in the investigation of peripheral iodine metabolism. In this case equilibration investigations result in rather low concentrations of radioactive iodine in body fluids and in tissues such as liver, kidney and skeletal muscle. It is no solution to this problem to increase the quantity of radioactivity injected, since this would subject the thyroid tissue to high doses of radiation and would affect thyroid function. The maintenance of normal levels of iodine compounds in the peripheral tissues clearly depends on the integrity of thyroid function. Feller, Chaikoff, Taurog and Jones[10] investigated the radiation dose-levels to thyroid tissue which would produce thyroid damage in the rat. Functional damage, causing changes in the plasma protein-bound iodine-levels, and impairment of the ability of the gland to concentrate and retain iodine, were observed after radiation doses to the thyroid tissue exceeding 100,000 reps. Histological change seemed to be a more sensitive index of radiation damage, and was seen in one experiment in which the dose was 46,000 reps. In the rat, in experiments lasting for a few days following administration of iodine-131, 24 μc appeared to act as a tracer dose, causing no radiation damage, whereas 300 μc always caused radiation damage.

It is possible that biochemical functions which have not yet been tested for radiation sensitivity may be more sensitive than those which have been used so far. For example, Anbar and Inbar[11] suggest that much lower radiation doses may damage the rat thyroid, because they found an increase of butanol non-extractable protein-bound iodine in the peripheral blood after such doses. Moreover, Basu, Lahiri and Chandhuri[28] have observed depression of thyroid function in the rat following doses ranging from 10 to 100 μc. Therefore, the discussion which follows will consider an experiment in which no more than 10 μc is administered to the rat. If the maximum uptake is 20 per cent of the dose, then at the time of maximum uptake the thyroid contains 2 μc iodine-131 If the thyroid weight is 10 mg this represents a concentration of 200 μc /g tissue The concentration present in the peripheral tissue varies a great deal from experiment to experiment, but is of the order of 10^{-4} of the thyroid concentration, that is, about 0 02 μc /g The largest amount of homogenized tissue which can be analysed by direct chromatography on paper, with or without prior pancreatin digestion[12], is about 1 mg, the chromatogram would thus contain a total of 20 μμc , which, after development, is distributed over a large area of the paper If the scan is to be of any real use it must be possible to measure the radioactivity of peaks amounting, at most, to 10 per cent of this, that is, 2 μμc In a source of this size there will occur only 4 4 disintegrations per minute The scanning of such chromatograms constitutes a low-level counting problem Only a counter with very high efficiency and a very low background is effective Such counters are not generally available and for this reason thyroid is the only tissue which can normally be analysed for radioactive iodine compounds by direct application of homogenates or hydrolysates on to paper chromatograms In practice, concentration techniques such as butanol extraction[13–15] or adsorption on to resins[16–18] are almost always used in the analysis of extrathyroidal tissues In these techniques there is a danger of deiodination[19] and esterification[20,21], moreover, recoveries are very rarely complete, so that some of the tissue iodine is unaccounted for We have constructed low-level counting systems in order to avoid the use of such concentration techniques in the analysis of non-thyroid tissue

Need for low-level counting in experiments involving administration of labelled iodine compounds While only the danger of radiation damage limits the amount of iodine-131 which can be administered in the form of carrier-free ^{131}I-iodide, the administration of labelled iodine compounds is often limited by their specific radioactivity It is not possible to produce samples of labelled amino-acids in which all of the iodine is present as iodine-131 Therefore, injection of the labelled compounds usually involves administration of a chemically appreciable amount of carrier along with the labelled material Care is necessary to ensure that the metabolism of the experimental animal is not altered by the administration of this carrier For example, in a commonly used technique for the preparation of labelled thyroxine[22] 0 68 mg diiodo-L-thyronine and 10 mc iodine-131 are used as the starting materials, and the product has a specific activity of 4 μc /μg The injection of only 4 μc of this material into the rat involves administering as much thyroxine as normally circulates in the blood of the rat, the level of protein-bound iodine-127 is probably doubled temporarily following the injection, so that the results may reflect physiological conditions which have been altered by the experiment The specific activity could only be improved by using less diiodothyronine or more radioactivity, and in an ordinarily equipped laboratory either measure presents difficulties Special methods have been utilized by Roche *et al* [23] and by Plaskett[24] to obtain thyroxine of much higher specific activity, but even if thyroxine containing 100 μc iodine-131 per μg is available, it is doubtful if it is advisable to administer more than 10 μc of it to the rat (As with the limitation of dose by radiation damage, the maximum dose which may safely be given is hard to define precisely Until more is known about the effects of giving carrier, the choice is unavoidably somewhat arbitrary) As in the analysis of extrathyroidal tissues after giving ^{131}I-iodide, low-level assay must be carried out if concentration techniques, with their many disadvantages, are to be avoided

Clinical investigations Finally, in clinical investigations with the human subject, in which tracer doses of iodine-131 are usually limited to about 20 μc , the results which can be obtained are very severely limited by problems of low-level assay

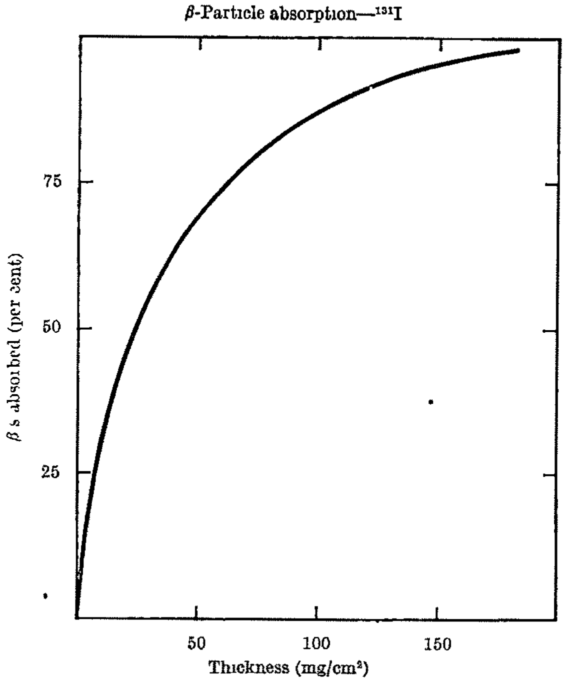

Fig 2 Absorption curve for iodine-131 β-particles

Nature of low-level sources In any of these applications of low-level counting the sources usually take the form of liquid samples or segments of chromatography paper Chromatography paper is sufficiently thin for a useful fraction of the β-particles to emerge from the source, and use can therefore be made of thin end-window Geiger–Muller counters Window thicknesses of just over 1 mg/cm^2 can be readily obtained (for example, 20th Century Geiger–Muller tube type *EW*2C), and since Whatman No 1 chromatography paper is about 10 mg/cm^2 this window thickness represents an unimportant addition to the absorption of the β-particles (Fig 2) An apparatus using such counters detects β-particles with high efficiency but has a very low efficiency for γ-rays

In liquid sources and other thick sources the β-particles are almost completely absorbed Such sources are most frequently assayed by detecting the γ-radiation in a well-type NaI crystal scintillation counter

Choice of Counting System The Relative Importance of Low Background and High Efficiency

For low-level counting systems the parameters to be considered are the background and the counting efficiency. If the background rate is R_2 counts per minute and the efficiency is ε, a source in which D atoms disintegrate per minute, each disintegration producing one β-particle will give a count rate due to the source alone of εD counts per minute The total count rate, including the background, will thus be $R_2 + \varepsilon D (= R_1)$ In practice R_2 is determined by obtaining n_2 counts in t_2 min and R_1 by obtaining n_1 counts in t_1 min The source rate (r) is then given by $R_2 - R_1$ The error in $R_2 - R_1$ is given by

$$\delta r = \sqrt{\frac{n_1}{t_1^{\,2}} + \frac{n_2}{t_2^{\,2}}} = \sqrt{\frac{R_1}{t_1} + \frac{R_2}{t_2}}$$

Differentiation shows that the best use of the total counting time, T, occurs when

$$t_1/t_2 = \sqrt{R_1/R_2}$$

These quantities can be related to the percentage error $x\left(x = \dfrac{100\delta r}{R_2 - R_1}\right)$ by the equation

$$T = \frac{10^4(\sqrt{R_2} + \sqrt{\varepsilon D + R_2})^2}{x^2\,\varepsilon^2\,D^2}$$

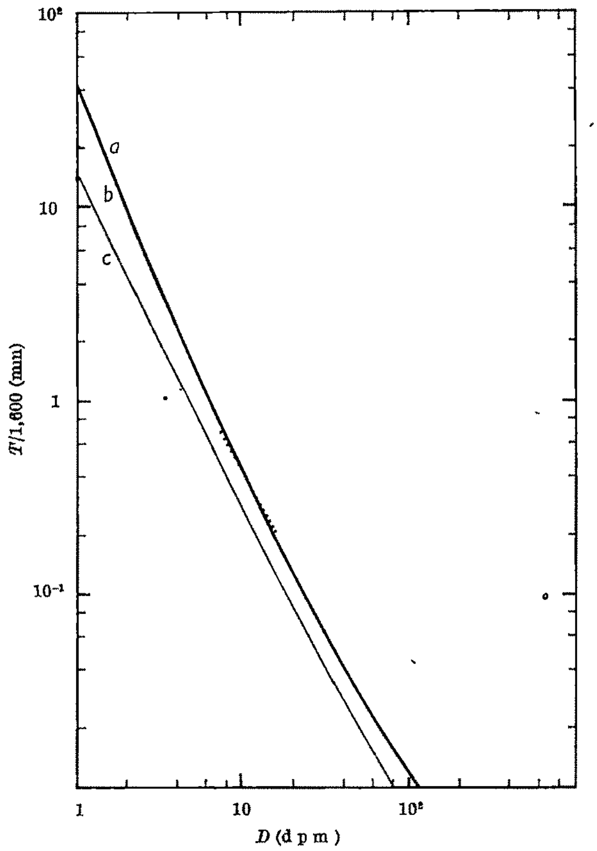

Fig. 3. T versus D curves for (a) efficiency = 0·5, background = 10 c.p.m.; (b) efficiency = 0·25, background = 1·5 c.p.m.; (c) efficiency = 0·5, background = 3·5 c.p.m.

which can be used to determine the properties of any counting system.

Components of the background. The importance of reducing the background of the counter is clear. By far the major components of this background are (1) the γ-rays from environmental radioactive contamination external to the apparatus, (2) cosmic ray mesons, (3) radioactive material in the counters themselves, and (4) spurious events arising in the electronic circuits associated with the system. For the thin window 20th Century Geiger–Muller counter type *EW2C*, a cylindrical counter about 2 in. long and 1 in. in diameter, the total background in a typical laboratory is of the order of 30 counts per min.

The first, and largest, component (environmental radiation) can be reduced by surrounding the counter with a high-density shield, usually lead, the background of the *EW2C* surrounded by 4 in. of lead is about 5 counts per min.

The cosmic ray mesons are normally reduced by surrounding the counter with a number of cosmic ray counters arranged in a semicircle above the counter and operated in anticoincidence. Since the μ meson intensity in any given direction is proportional to the square of the cosine of the angle to the vertical the most important counters are those nearest the top of the ring and the ones making large angles with the vertical are often dispensed with. The μ meson rate in the counter under discussion is about 3·5 per min and so the background in the shielded counter run in anticoincidence with cosmic ray counters is reduced to about 1·5 counts per min.

The component due to radioactivity in the counter itself must be accepted and the spurious pulses in the associated circuits and mains pick-up can be eliminated by proper design and construction.

Efficiency. The efficiency of the counter for iodine-131 uniformly distributed on a small piece of Whatman No. 1 chromatography paper is about 25 per cent. Only 50 per cent of the betas go in the direction of the counter and about half these are absorbed before they enter the sensitive volume of the counter. Some β-particles will, of course, have path-lengths in the paper considerably longer than the thickness of the paper, since they will travel at a steep angle through it.

The efficiency of the system is immediately doubled if two counters are used, viewing opposite sides of the paper. To illustrate how performance is related to efficiency and background let us consider two systems, one using two counters face to face, shielded by 4 in. of lead, and the other having one similarly shielded counter but surrounded by an anticoincidence ring of cosmic ray counters. We have seen that the efficiencies and backgrounds of these will be 0·5 and 10 counts per min and 0·25 and 1·5 counts per min respectively. The variations of the total counting time, T, for a 5 per cent error, with the amount of iodine-131 in the source, D, is shown in Fig. 3. It will be seen that at $D = 12$ disintegrations per min (that is, about 5 μμc.) the two systems are equivalent, for sources containing less than this amount of activity the system with the lower background and efficiency is superior, and for sources of more than 12 disintegrations per min the higher background and efficiency is best. It is therefore desirable to choose the system according to the amount of activity to be counted.

Low-level scanning of paper chromatograms. The double counter system has been routinely used by us for scanning paper chromatograms. It is surrounded by an efficient anticoincidence shield which reduces the background to 3·5 counts per min, the efficiency remains at 0·5. The curve for this arrangement is shown in Fig. 3, and it will be clearly seen that for very low activities the low background system is very advantageous, but the difference between the double-counter, with and without anticoincidence, quite rapidly lessens with increasing D. An advantage of the lower-background system is that the occurrence of spurious pulses is more easily detected. It is always very difficult to verify the absence of such events, but if the background, and consequently the standard deviation of the background, is low, the presence of such pulses becomes more apparent. The background of the double-counter system with anticoincidence is somewhat greater than twice the background of the single counter with anticoincidence. This is because a significant fraction

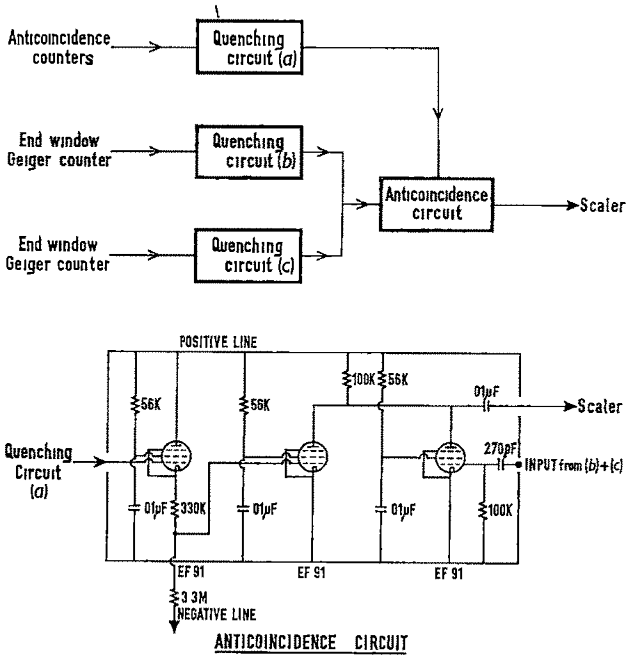

Fig. 4. Electronic arrangement for low-level counter

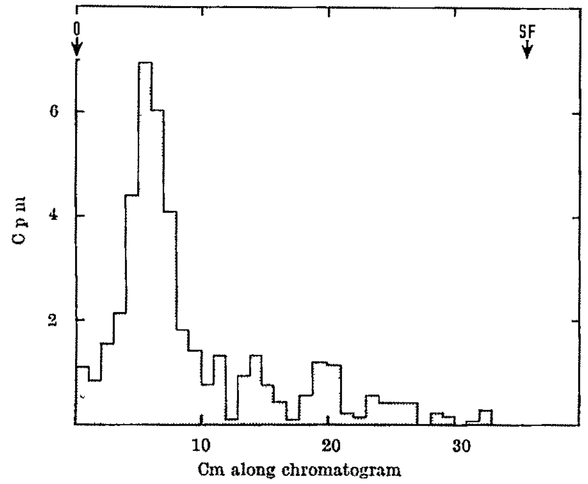

Fig 5 Chromatogram scan of a pancreatin digest of liver homogenate from a rat killed after injection of ^{131}I-iodide

of the radioactive contamination in the counter occurs in the mica window With two counters, radiation from one window travelling in the direction of the other counter can trigger it off, and since there is twice the amount of activity present the background from this source, compared with the single counter, may be greater by a factor of up to 4 From measurements on several samples of mica it was concluded that this source accounted for almost half the background in the double counter system

Electronic circuits which have given satisfactory service over a long period in a double-counter system with anticoincidence are shown in Fig 4 The anticoincidence array consisted of 12 *G*60 Cintel Geiger–Muller counters arranged in a semicircle The quenching circuits were of a standard type One valve of the Rossi-type anticoincidence circuit was cut off permanently by a standing bias. Positive square pulses from the quenching circuit attached to the anticoincidence ring lifted this bias and no pulse was passed to the scaler when pulses arrived at the grids of both Rossi valves simultaneously (that is, when a meson passed through the apparatus) In the absence of a pulse to lift this bias a pulse at the grid of the first valve gave an output pulse to the scaler The pulses from the quenching circuit feeding the first valve were delayed for a short time to ensure efficient anticoincidence operation There is some loss in efficiency due to the paralysis time of the quenching circuit associated with the anticoincidence ring, but this should not exceed 1 per cent The anticoincidence device can be made nearly 100 per cent efficient if the counters are slightly overlapped to prevent mesons leaking through spaces between counters

Experimental work using this counting system has already been published[9,25] in connexion with investigations on intrathyroidal iodine metabolism Since the greatest test of low-level counting methods occurs in the examination of peripheral iodine metabolism, a chromatogram scan is presented in Fig 5, which was obtained by chromatographing directly a pancreatin digest of liver homogenate from a rat killed 44 h after injection of ^{131}I-iodide Most of the radioactivity was located in a single peak with a low R_F value, which, in the solvent system used, butan-1-ol/dioxan/2 N ammonia (4 1 5), corresponds in position to the iodothyronine glucuronides The position and shape of the peak have been accurately defined even though the total radioactivity of the chromatogram did not exceed 30 μμc It was possible to elute the radioactivity of this peak from the chromatogram and to show that after hydrolysis with a *Patella vulgata* β-glucuronidase preparation it exhibited the chromatographic properties of thyroxine The compound, therefore, resembles a thyroxine conjugate previously isolated from mouse kidney by Galton and Pitt-Rivers[26]

Measurement of thick sources For liquid sources and other thick sources the most common method of measurement involves the use of a sodium iodide (Tl) well-type crystal Commonly a crystal of about 2 in diameter and 2 in deep is used with a well $\frac{5}{8}$ in × $1\frac{1}{2}$ in The mean path-length for γ-rays in the crystal will be about 1 in and the total number of interactions from iodine-131 γ-rays (photo-electric plus Compton) will be about 47 per cent of the number of disintegrations In practice the 364-keV photoelectric peak is found to contain about 50 per cent of the total number of events, which agrees with the theoretical prediction that about 24 per cent of the disintegrations will produce 364-keV photoelectrons A good crystal should, in practice, give a 364-keV photopeak resolution (ratio of width of peak at half-amplitude to peak position) of about 12 per cent Assuming a photoconversion efficiency of 36 eV/photon for sodium iodide and a photocathode efficiency of 10 per cent for the photomultiplier, a resolution of about 8 per cent is theoretically possible This is never realized in practice, probably owing to losses of photons by absorption and on reflexion from the sides of the crystal

It is necessary to consider whether it is advantageous to use single channel analysis to count only the photopeak, thereby reducing the background count The background in the photopeak region of a typical sodium iodide crystal of the dimensions mentioned and shielded by 3-in thick lead is about 25 counts per min If the bias of the apparatus is set so that all events above an energy of 50 keV are recorded, then the background will increase to about 150 counts per min We have, then, to compare a system with an efficiency of 0 25 and background of 25 counts per min with one having an efficiency of 0 47 and background 150 counts per min The curves obtained for these situations are shown in Fig 6 It will be seen that for low activities (< 100 μμc) single channel pulse-height analysis is preferable, but that, in the range con-

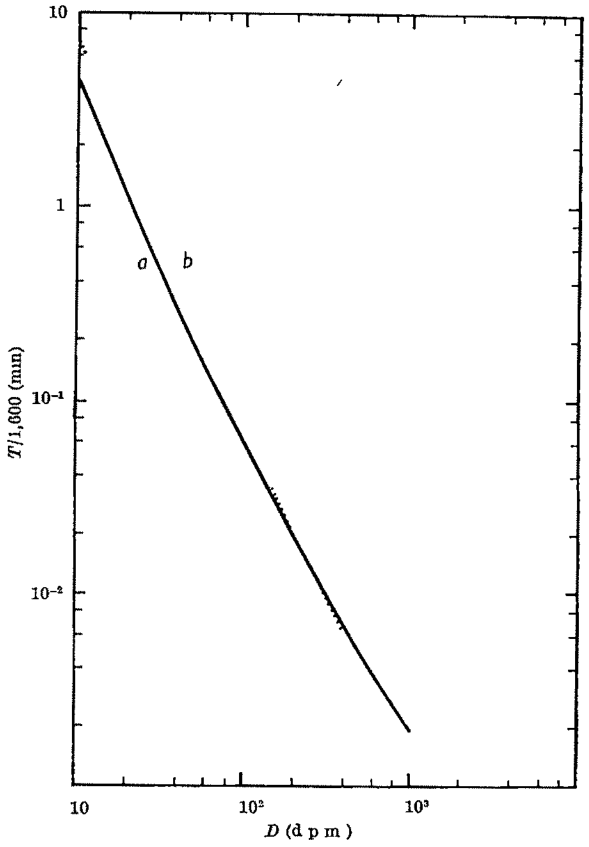

Fig 6 *T* versus *D* curves for (*a*) efficiency = 0 25, background = 25 c p m , (*b*) efficiency = 0 47, background = 150 c p m

sidered, the two systems are roughly equivalent above this level

Newly developed counting methods The systems described here are now sufficiently well developed to be in regular use. In another, less well developed method, thin sources of iodine-131 can be measured by counting the β-particles with a thin plastic phosphor To absorb completely the β-particles a phosphor about 3 mm thick would be required A typical plastic phosphor, such as *p*-terphenyl in polystyrene, must absorb about 200 eV from the energy of a β-particle to produce a photon of light A typical photomultiplier has a photocathode efficiency of about 10 per cent and, therefore, an energy of 2 keV is required to produce one photoelectron at the photocathode, assuming that all the photons are collected In practice, it is extremely difficult to collect every available photon and it is probably more realistic to base calculations on a figure of 3 keV/photoelectron It would be necessary to bias the apparatus to cut out the photomultiplier noise and, since a standard photomultiplier produces a significant number of noise pulses of up to about 5 electrons the bias would have to be set at a point which would eliminate the measurement of β-particles entering the phosphor with energies less than 15 keV This is an optimistic figure since the bias would most likely have to be set higher to allow for temperature variation in the noise This system in its simplest form of a thin phosphor, viewed by one photomultiplier and silvered on the back face to reflect light into the photomultiplier, is therefore, from the point of view of efficiency, fundamentally worse than the Geiger–Muller counter system To compare with the best Geiger system the background in the phosphor would have to be significantly lower than is, in practice, attainable Some improvement could be made by using a double system and running the photomultipliers in coincidence The elimination of photomultiplier noise would allow the bias to be set lower and the β-particles from both sides of the source would be counted Fast, reliable, coincidence circuits are, however, difficult to design and maintain It would also be difficult to devise a simple system to introduce the source between the two phosphors—the method used would have to combine the requirements of light tightness and minimum absorbing material between source and phosphor If these difficulties can be solved, then the double phosphor system would offer an attractive method for counting thin sources of iodine-131, especially since the dimensions of the phosphor could be matched to those of the source, thus minimizing the background

Another technique for counting low-activity sources of iodine-131 involves the use of a sodium iodide crystal working in coincidence with a thin-window Geiger–Muller counter Pulses are registered when the 364-keV γ-ray is recorded by the scintillation counter and the 600-keV cascade β-particle is recorded simultaneously by the β-counter. Using a single channel pulse-height analyser with the sodium iodide counter, very low backgrounds can be obtained With counters of 1 in diameter operating face to face, the source being placed between them, we have obtained efficiency of about 8 per cent with a background of 1 or 2 per hour These figures could be improved with a more favourable geometry This counter has an obvious application for the rapid determination of the presence of activity, even if the efficiency cannot be made large enough to allow quantitative estimates of radioactivity to be made in a time short enough to compete with other methods

Finally, mention must be made of the future use of solid conduction counters for chromatogram scanning These counters are now being rapidly developed[27] and will, no doubt, eventually provide an excellent method for the low-level counting of iodine-131 Because of this thinness of the active volume of the counter the backgrounds are potentially very low, but unfortunately the noise pulses in the presently available counters are so large that the bias has to be set at a level which cuts out a significant fraction of the pulses from the lower energy β-particles The efficiency of the available counters is therefore low but great efforts are being made to improve this

2,5-DIHYDRO-2-FUROIC ACID: A PRODUCT OF THE ANAEROBIC DECOMPOSITION OF ASCORBIC ACID

By I. M. COGGIOLA

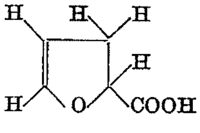
C.S.I.R.O. Division of Food Preservation, North Ryde, New South Wales, Australia

THE anaerobic decomposition of ascorbic acid was studied by Huelin[1], who identified the products furfural and carbon dioxide His report that loss of ascorbic acid from an unbuffered aqueous solution involved an increase of *p*H was not confirmed—the formation of other acids resulted in little net change in *p*H

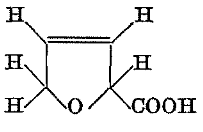
A 5 per cent (w/v) solution of ascorbic acid in glass-distilled water was incubated at 100° C under an atmosphere of carbon dioxide for 10 days until decomposition was practically complete The acids were separated by displacement ion-exchange chromatography[2] The fractions containing the predominant acid were combined and freeze-dried, to give a brown semi-crystalline material The methyl ester was prepared by reaction with diazomethane

The *p*H titration curve of the acid showed the presence of one carboxyl group (*p*K, 3 2) The absence of carbonyl groups was shown by its failure to react with 2,4-dinitrophenylhydrazine Hydrogenation of the methyl ester indicated the presence of one double bond The infra-red spectrum of the acid showed a carboxyl group at 1,727 cm^{-1} and the infra-red spectrum of the methyl ester after gas chromatography showed that hydroxyl groups were absent As further purification of the acid was unsuccessful, and as its purity was inadequate for elementary analysis, the *cyclo*hexylamine salt was prepared as colourless needles m p 160°–163° C (decomp) Analysis of this salt gave C, 62 2, H, 9 2, O, 22 5, N, 6 5 per cent Calc for $C_{11}H_{19}O_3N$ C, 61 9, H, 9 0, O, 22 5, N, 6 6 per cent This would give a formula of $C_5H_6O_3$ for the isolated acid (calc equiv wt 114, found, 116) As two of the oxygen atoms are involved in the carboxyl group, the remaining one, which belongs neither to a carbonyl nor to a hydroxyl group, must be involved in an ether linkage The foregoing evidence indicates the possibility of a dihydrofuroic acid

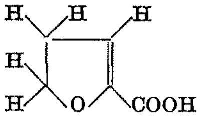
Sublimation under high vacuum with the application of heat was attempted as a means of purification, but resulted in decomposition, with the formation among other products of 2-furoic acid, m p 132°–133° C The infra-red and nuclear magnetic resonance spectra were identical with those of an authentic sample of 2-furoic acid. Analysis gave C, 53 6, H, 3 7, O, 42 5 per cent, calc for $C_5H_4O_3$ C, 53 6, H, 3 6, O, 42 8 per cent From this it could be assumed that the carboxyl group is in the 2-position The acid could have one of the structures I, II or III



(I)



(II)



(III)

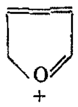
The nuclear magnetic resonance spectra of the acid and its methyl ester were determined at 60 Mc/s in deuterochloroform solution Signal positions are given in p p m from tetramethylsilane as internal reference The spectrum of the acid consisted of multiplets at 4 8 p p m (2 protons, essentially an *AB* quartet with J_{AB} approximately 12 c/s and split further by several protons), 5 3 p p m (1 proton), and 6 0 p p m (2 protons, essentially an *AB* quartet with J_{AB} = 6 3 p p m and further splitting due to interaction with several protons), and a singlet at lower field (position variable with concentration), which disappeared on treatment with deuterium oxide[3] and must be due to the carboxylic hydrogen

The spectrum of the ester showed multiplets at 4 8 p p m (2 protons), 5 2 p p m (1 proton), and 6 0 p p m (2 protons), all having the same structure as the corresponding signal in the spectrum of the acid, and a singlet at 3 7 p p m (3 protons) which must be due to the ester methoxyl

The position and principal coupling constants of the two two-proton multiplets are consistent with the presence of a di-substituted *cisoid* double bond and a methylene group with non-equivalent protons (for example, in a ring) The position of the resonances[4] and the presence of additional splitting, due to long-range interaction[5], are entirely consistent with structure II for the acid and ester respectively

The presence of a signal due to two vinylic protons in the nuclear magnetic resonance spectrum (multiplet at 6 0 p p m) excludes structure III, which is also inconsistent with the ultra-violet spectrum, which showed no strong absorption The long-range interactions causing the fine splitting in the nuclear magnetic resonance spectrum are consistent with structure II In particular, the signal attributed to the proton on C-2 (at 5 3 p p m) would be expected to be much less complicated in structure I than in II due to the absence of homoallylic interactions[6] The position of the resonance assigned to the ring methylene protons (4 8 p p m) is consistent only with structure II, in structure I this resonance would be expected to occur much farther upfield[4]

The mass spectrum of the ester was determined on an Atlas-Werke model *CH*4 spectrometer and showed only one main peak at m/e 69 which is attributed to the resonance stabilized ion IV The absence of the parent peak, even at low energy, is entirely consistent with structure II (ref 7)



(IV)

The predominant acid isolated is considered to be 2,5-dihydro-2-furoic acid

I thank Drs J S Shannon and S Sternhell, of the C S I R O Division of Coal Research, for the mass and nuclear magnetic resonance spectra respectively, and for their interpretation

ORIGIN OF SODIUM CONCENTRATION PROFILE IN THE RENAL MEDULLA

By Dr G G. PINTER*

Department of Physiology, School of Medicine, University of Maryland

AND

Dr J L. SHOHET

Department of Electrical Engineering, Johns Hopkins University, Baltimore

In recent years, mathematical models have been described with the purpose of simulating the function of the Henle loops on one hand and the role of the vasa recta on the other Hargitay and Kuhn[1] and Kuhn and Ramel[2] presented the countercurrent multiplier hypothesis for the operation of the Henle loops These authors took the presence of the collecting ducts into consideration, but omitted the vasa recta as an integral part of the system Similarly, Gunzler[3] derived equations for the concentration profile in the vasa recta without paying attention to the presence of the Henle loops

* Holder of U S Public Health Service research career development award

These models have been successful in predicting most of the experimental results obtained by chemical analysis of the medullary tissue and by micropuncture studies It appears however, that they do not readily offer an explanation for the sodium concentration profile found in the renal medulla of well-hydrated animals[4] As reported by Levitin *et al*[5] and by Boylan and Asshauer[6] in water diuresis, the concentration of tissue sodium may show an increase from the cortico-medullary border to an internal layer of the medulla whereupon it may decrease toward the papilla Furthermore, the hypotheses dealing separately with the Henle loops and vasa recta do not eliminate the doubt expressed by Smith[7] that a sudden change in sodium-transporting activity and water permeability of the cells lining the thin segment of the Henle loop at the turning point is not warranted by the histological picture

In this article we propose an integrated model which takes into account the interaction between Henle loops and vasa recta The operating unit of our model is a small segment of the medullary interstitium into which are immersed one Henle loop and one vas rectum (Fig 1) For the sake of simplicity, we disregard momentarily the presence of the collecting ducts, the influence of which will be considered later Apparently, lymph vessels are not present in the medulla[8]

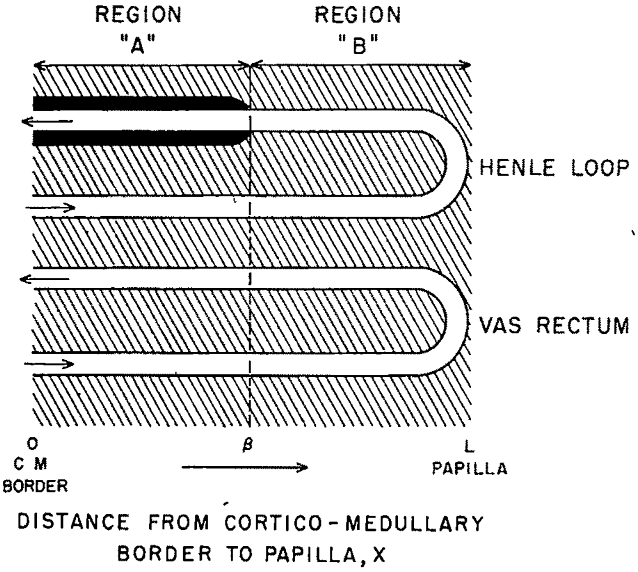

Fig 1 Operating elementary unit

We assume that sodium moves across the wall of the vasa recta and that of the thin segment of the Henle loops according to the concentration difference between the lumen and interstitium, while the wall of the thick segment of the ascending Henle loops transports sodium out of the lumen into the interstitium at any point at a rate which is proportional to the sodium concentration in the lumen In other words, in this model the countercurrent multiplier action of the Henle loop is restricted to the region where the ascending limb is thick walled (region *A* in Fig 1) The function of the thin segment of the Henle loops and of the entire vasa recta is to wash the sodium from the interstitium of the countercurrent multiplier region toward both cortex and papilla depending on the direction of flow in these channels It is further assumed that the diffusion of sodium in the medullary interstitium is predominantly perpendicular to the course of the Henle loops and vasa recta, that is, the process of sodium diffusion in the cortico-papillary direction may be neglected Again, the system is in equilibrium, that is, the amount of sodium moving into equals the quantity moving out of our operating elementary unit

The following boundary conditions are assumed (1) The input concentrations in both tubes are known and constant (2) Flow rate and output concentration in both tubes are interdependent variables affecting the shape of the concentration profile in the medulla

The system is divided into two regions (Fig 1) Region *A* will be the area between the entrance to the system and point β Region *B* will be the area between point β and the turning point of the tube Two sets of coupled equations can then be written for region *A* and region *B* In all, ten interdependent differential equations describe the concentrations prevailing in the ascending and descending Henle loops and vasa recta as well as in the interstitium, 5 in region *A* and 5 in region *B* The equations for region *A* are

$$\frac{\partial c}{\partial x} = k(j - c) \qquad (1)$$

$$\frac{\partial c'}{\partial x} = k(j - c') \qquad (2)$$

$$\frac{\partial c_h}{\partial x} = k_h(j - c_h) \qquad (3)$$

$$\frac{\partial c_h'}{\partial x} = k_h' c_h' \qquad (4)$$

$$\frac{\partial j}{\partial x} = k(c - j) + k(c' - j) + k_h(c_h - j) + k_h' c_h' \qquad (5)$$

where c is the concentration in the descending limb of the vas rectum, c' is the concentration in the ascending limb of the vas rectum, c_h is the concentration in the descending part of the Henle loop and c_h' is the concentration in the ascending part of the Henle loop j is the interstitial concentration, k the 'catch-all' membrane coefficient for the vasa recta, k_h the coefficient for the Henle loop and k_h' the coefficient for the thick-walled segment of the Henle loop x, the distance, is measured from the cortico-medullary boundary towards the papilla

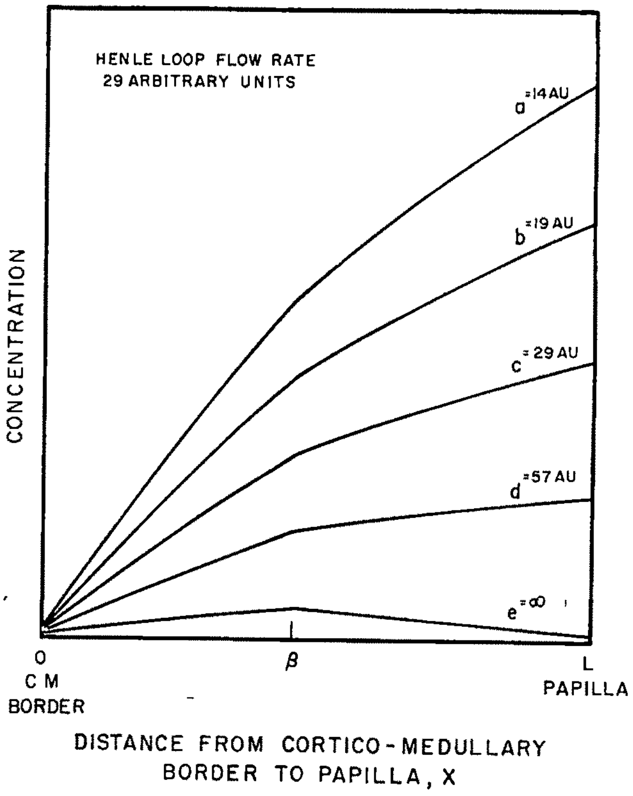

Fig 2 Interstitial concentration in the renal medulla with vasa recta flow rates of 14, 19, 29, 57, and infinite number arbitrary units (AU) and Henle loop flow rate of 29 arbitrary units

The corresponding equations for region B are identical to those for region A except for (4) and (5) which are now

$$\frac{\partial c_h'}{\partial x} = k_h(j - c_h') \qquad (6)$$

$$\frac{\partial j}{\partial x} = k(c - j) + k(c' - j) + k_h(c_h - j) + k_h'(c_h' - j) \qquad (7)$$

The system of equations may then be solved with the appropriate boundary conditions and the requirements that the solutions in region A and region B must match at point β, and that at the turning points c must equal c' and c_h must equal c_h' It will also be assumed that the rate of change of concentration with respect to x in the input of both tubes and at $x = 0$ in the interstitium are identically equal to zero

The equation for c gives

$$c = A + Be^{p_1x} + Ce^{p_2x} + De^{p_3x} + \frac{c_{h_0}'}{4}\left[\frac{k_h'^2}{kk_h} + \frac{k_h'}{k} + \frac{k_h'}{k_h} + 1\right]^{-1} e^{l_h'x} \qquad (8a)$$

in region A, where p_1, p_2 and p_3 are found from the solution of the determinental equation

$$\frac{p^3}{k^2k_h} + \left[\frac{2}{k^2} + \frac{4}{kk_h}\right]p^2 + \left[\frac{6}{k} + \frac{3}{k_h}\right]p + 4 = 0$$

and c_{h_0}' is the output concentration of sodium from the Henle loop and

$$c = \bar{A} + \bar{B}e^{\bar{p}_1x} + \bar{C}e^{\bar{p}_2x} + \bar{D}e^{\bar{p}_3x} \qquad (8b)$$

in region B, where p_1, p_2 and p_3 are found from the solution of the determinental equation

$$\frac{\bar{p}^3}{k^2k_h} + \left[\frac{3}{k^2} + \frac{4}{k_hk}\right]\bar{p}^2 + \left[\frac{8}{k} + \frac{3}{k_h}\right]\bar{p} + 5 = 0$$

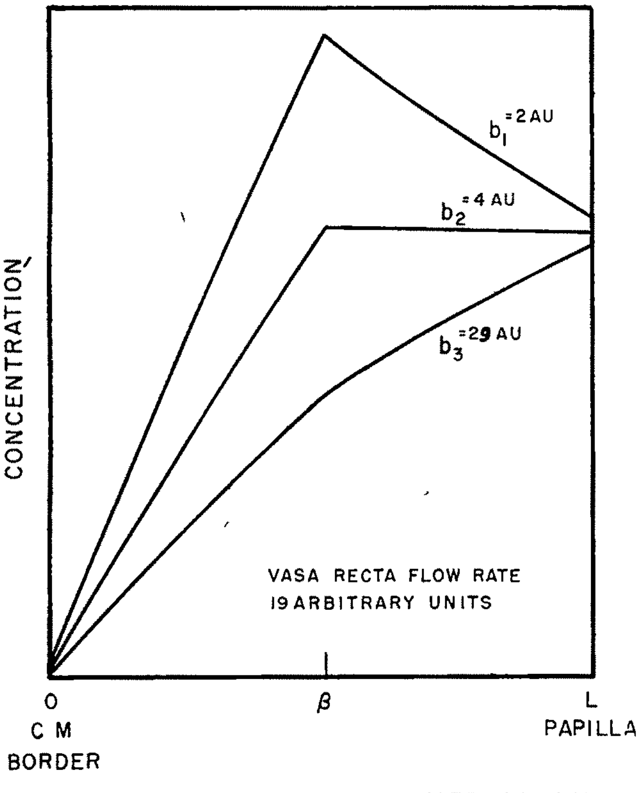

Fig 3 Interstitial concentration in the renal medulla with Henle loop flow rates of 2, 4, and 29 arbitrary units and vasa recta flow rate of 19 arbitrary units

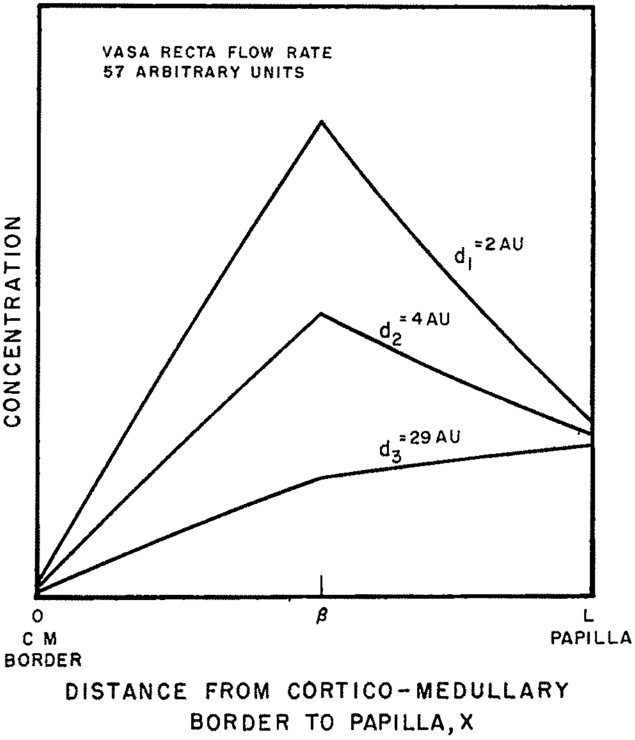

Fig 4 Interstitial concentration in the renal medulla with Henle loop flow rates of 2, 4, and 29 arbitrary units and vasa recta flow rate of 57 arbitrary units

The coefficients A, B, C, D, $\bar{A}$, $\bar{B}$, $\bar{C}$ and $\bar{D}$ are evaluated from the boundary conditions

The solution for c' is identical in form to that of c, except for different coefficients A', B', C', D', $\bar{A}'$, $\bar{B}'$, $\bar{C}'$ and $\bar{D}'$ The exponents are identical

The results for c_h are

$$c_h = A_h + B_he^{p_{h_1}x} + C_he^{p_{h_2}x} + \frac{c_{h_0}'}{4}\left[\frac{k_h'}{k_h} + 1\right]^{-1} e^{l_h'x} \qquad (9a)$$

in region A, where p_{h_1} and p_{h_2} are evaluated from the solution of

$$\frac{p_h^2}{kk_h} + \left[\frac{3}{k_h} + \frac{2}{k}\right]p_h + 4 = 0$$

and

$$c_h = \bar{A}_h + \bar{B}_he^{\bar{p}_{h_1}x} + \bar{C}_he^{\bar{p}_{h_2}x} + \bar{D}_he^{\bar{p}_{h_3}x} \qquad (9b)$$

in region B, where the exponents are found from the solution of

$$\frac{\bar{p}_h^3}{k_h^2k} + \left[\frac{3}{k_h^2} + \frac{4}{kk_h}\right]\bar{p}_h^2 + \left[\frac{8}{k_h} + \frac{3}{k}\right]\bar{p}_h + 5 = 0$$

c_h' is found to be

$$c_h' = c_{h_0}' e^{k_h'x}$$

in region A, and of exactly the same form as c_h in region B with coefficients $\bar{A}_h'$, $\bar{B}_h'$, $\bar{C}_h'$ and $\bar{D}_h'$.

Finally, j, the concentration in the interstitium, is found directly from equation (1) since the solution for c is known It is then

$$j = A + B\left(1 + \frac{p_1}{k}\right)e^{p_1x} + C\left(1 + \frac{p_2}{k}\right)e^{p_2x} + D\left(1 + \frac{p_3}{k}\right)e^{p_3x} + \frac{c_{h_0}'}{4}\left[1 + \frac{k_h'}{k}\right]\left[\frac{k_h'^2}{kk_h} + \frac{k_h'}{k} + \frac{k_h'}{k_h} + 1\right]^{-1} e^{k_h'x} \qquad (10a)$$

in region A, and:

$$y = \bar{A} + \bar{B}\left(1 + \frac{\bar{p}_1}{k}\right)e^{\bar{p}_1 x} + \bar{C}\left(1 + \frac{\bar{p}_2}{k}\right)e^{\bar{p}_2 x} + \bar{D}\left(1 + \frac{\bar{p}_3}{k}\right)e^{\bar{p}_3 x} \qquad (10b)$$

in region B. Note that the solutions to all these equations depend on the membrane coefficients, the flow rates when the boundary condition of equilibrium is applied and the input concentrations. The actual solution of the equations for the concentration at any point depends on the membrane coefficients and flow rates in both channel systems. It was assumed that the parameter which is the most readily regulated physiologically is the flow rate in the vasa recta and in the Henle loops. The equations were put on an analogue computer connected to an X–Y plotter whereby the behaviour of the concentration profiles in ascending and descending Henle loops, vasa recta and in the medullary interstitium could be observed under changing flow rates in the vascular and tubular channels. Figs. 2, 3 and 4 represent results from the computor for the concentration profile in the medullary interstitium under varying flow rates in the vasa recta and in the Henle loop. On these graphs the abscissa represents the site in the medulla from the cortico-medullary border to the turning point of the channels and the ordinate is measured in terms of Na concentration.

In Fig. 2, the Henle loop flow rate was held constant at 29 arbitrary units and the vasa recta flow rate was varied as follows: curve *a*, 14, curve *b*, 19, curve *c*, 29, curve *d*, 57, curve *e*, a very large number (∞) arbitrary units. It may be pointed out that under the conditions of finite flow specified in Fig. 2 the Na concentration continues to rise throughout the entire length extending from the cortico-medullary border to the papilla. A continuous rise in sodium concentration which extended from the cortico-medullary border up to the papilla was also observed in both limbs of the Henle loop and vasa recta. To our knowledge it is this finding, namely, that in hydropenic animals the increase of sodium concentration extends up to the papilla, which leads to the inference that the Henle loop operates as a countercurrent multiplier in its entire length. From the graphs it can be seen that such an inference is not necessary in a model in which the countercurrent multiplier operation is limited to the portion of the Henle loops where the ascending limbs have thick walls. Such a model may create continuously increasing sodium concentration if its action is co-ordinated with the function of the vasa recta. In Figs. 3 and 4 the vasa recta flow rates were held constant and the Henle loop flow rates were varied. These graphs indicate that our model may duplicate conditions in which the highest sodium concentration is found in a middle layer of the medulla. Our model predicts that this layer will be one in which the beginning of most of the thick segments of the ascending Henle loops is found.

It may be assumed that the collecting duct contributes a constant amount of solute and/or water to the medullary interstitium along its entire length. This operation shifts the concentration profile upwards or downwards, respectively, by an amount proportional to the product of the amount added times the longitudinal distance. If the rate of transport of water or solute across the wall is not constant, the influence is more complex, but it is not expected that it would basically change the shape of the concentration curve.

LABILE FLAVIN ADENINE DINUCLEOTIDE OF HEART MUSCLE PREPARATIONS

By DR. TERENZIO CREMONA*, DR. EDNA B. KEARNEY, DR. JAMES SALACH
and DR. THOMAS P. SINGER

Edsel B. Ford Institute for Medical Research, Henry Ford Hospital, Detroit

MASSEY and Swoboda[1] recently reported that on storage at 4° of heart muscle preparations isolated by a modification of Keilin and Hartree's method[2] there is a gradual decrease in the acid-extractable FAD content and corresponding increase in the FMN content. While the supporting results presented are convincing, so far as this preparation is concerned, the claims of these authors that the same breakdown occurs in Keilin–Hartree preparations isolated by mechanical grinding and differential centrifugation[3] are less convincing. Massey and Swoboda concluded that (*a*) within experimental error FAD is the only acid-extractable flavin present in fresh heart mitochondria, (*b*) that any enzyme isolated from this source which contains FMN is likely to be an artefact. Conclusion (*a*) agrees with the earlier report of Ziegler *et al.*[4] that more than 90 per cent of the acid-extractable flavin content of heart mitochondria is FAD. For conclusion (*b*), Massey and Swoboda quoted the example of DPNH-cytochrome reductases isolated from heart, all of which have now been shown to contain only FMN (refs. 5 and 6) and to be degradation products of the DPNH dehydrogenase of the respiratory chain[6,7]. Since purified preparations of DPNH dehydrogenase had been reported to contain both FAD and FMN (ref. 8), Massey and Swoboda[1] further suggested that even this preparation may be modified to some extent.

According to as yet unpublished reports, Merola and Coleman[9] and Nickel *et al.*[10] could not confirm these results and affirmed that the FMN present in certain heart muscle preparations is not an artefact due to ageing. The former authors based their conclusions on ageing of beef heart mitochondria at −20°, while Nickel *et al.* examined the effect of storage at 0°–4° on Keilin–Hartree preparations isolated by mechanical grinding and differential centrifugation. Thus the conditions used by both groups deviate from those utilized in most of the experiments of Massey and Swoboda and, hence, do not bear on the experimental findings, although they are relevant to these authors' conclusions.

In view of the obvious interest of the phenomenon and its implications on many problems concerning respiratory enzymes, including the question of the prosthetic group of DPNH dehydrogenase[1], we wish to report that we have confirmed fully the findings of Massey and Swoboda as regards acid precipitated Keilin–Hartree preparations but have not been able to observe a similar breakdown of FAD in mitochondria or in Keilin–Hartree samples prepared at neutral pH.

Table 1 STABILITY OF FAD IN BEEF HEART MITOCHONDRIA

Exp	Preparation	Acid-extractable flavin (mμmoles/mg protein)	FAD/total acid-extractable flavin (per cent)	Total acid-extractable flavin (μmoles)	Total FAD (μmoles)	Total FMN (μmoles)
1	Fresh BHM, rapid preparation (2–3 h after killing)	0 32	84			
2	Normal, fresh BHM (5–6 h after killing)	0 38	85			
3	Frozen stored BHM (same as Exp 2, after 3 days at −15° in sucrose–PO$_4$)	0 39	85			
4	Mitochondria stored at 4° in sucrose–PO$_4$					
	Immediately after preparation	0 33	85			
	24 h later	0 38	86			
	92 h later	0 32	82			
5	Fresh BHM	0 38	85	15 4	12 8	2 60
	First centrifugation residue	0 42	84	14 1	11 8	2 26
	,, ,, supernatant	0 24	71	1 34	0 96	0 38
	,, ,, sum			15 4	12 8	2 60
	Second centrifugation supernatant	0 18	81	0 40	0 32	0 075
	,, ,, residue (ETP)	0 28	69	0 93	0 64	0 291
	,, ,, sum			1 34	0 96	0 37

Beef heart mitochondria (BHM) and ETP were prepared exactly as per Ringler *et al* (ref 8) Total flavin, FAD, and FMN were analysed by differential fluorometry in 5 per cent TCA extracts Protein was determined by the biuret method with the coefficient of 0 095 Samples were stored in 0 25 M sucrose–0 01M phosphate, *p*H 7 4 In Exp 5 40 5-g fresh BHM were processed all the way to the ETP stage without storage The supernatant solution from the first centrifugation (7 min at 19,000*g*) is recentrifuged at 106,000*g* for 30 min, the neutralized pellet is the ETP

Table 2 STABILITY OF FAD IN KEILIN–HARTREE PREPARATIONS

Prepared at neutral *p*H					Acid precipitated preparation				
Hours after killing	Acid extractable flavin (mμmoles/mg protein) Total	FMN	FAD	FAD/total flavin (per cent)	Hours after killing	Acid extractable flavin (mμmoles/mg protein) Total	FMN	FAD	FAD/total (per cent)
4 6	0 302	0 100	0 231	77	7	0 358	0 072	0 328	92
28	0 303	0 102	0 230	76	27 5	0 362	0 091	0 310	86
52	0 302	0 100	0 199	77	51 5	0 370	0 123	0 283	77

The Keilin–Hartree preparation isolated at neutral *p*H was prepared by means of grinding in a mechanical mortar (at 4°) and differential centrifugation, following the previously described modification (ref 8) of King's procedure (ref 3) The average time for preparation was 4 h The acid precipitated sample was made exactly according to Massey and Swoboda (ref 1) The average time for preparation was 3 5 h

Table 1, Exps 1 and 2, shows that beef heart mitochondria, whether prepared rapidly or by the normal procedure, contain the same ratio of FAD to total flavin and (Exps 3 and 4) this ratio remains constant on several days' storage at 4° or at −15° Exp 5 demonstrates that in the preparation of ETP (the source of DPNH dehydrogenase[8]) no FAD is destroyed nor is FMN formed It may be concluded that the breakdown of FAD observed by Massey and Swoboda is not a characteristic property of mitochondrial flavoproteins Elsewhere[11] it has been shown that storage of ETP for 2 weeks at −15° causes no breakdown of FAD and that if the isolation of DPNH dehydrogenase is carried out within a period of 24 h of the killing of the animal, without interruption, the same FMN content is found in the resulting preparations as in samples purified over a period of several days from stored mitochondria Thus the observations of Massey and Swoboda do not seem to have any direct bearing on the flavin moiety of DPNH dehydrogenase

It should be noted that the FAD to total flavin ratio reported in Table 1 (82–86 per cent) for mitochondria is the value which has been found over many years of analyses of heart mitochondria in this laboratory and agrees very well[12] with the values reported by Massey and Swoboda[1] and Rao *et al* [5], but not with those of Merola and Coleman[9] or of King *et al* [13]

Table 2 demonstrates that while Keilin–Hartree preparations isolated at neutral *p*H show no breakdown of FAD, those prepared by Massey and Swoboda's technique[1] show a higher initial FAD and total flavin content and a tendency for a gradual decline in the ratio of FAD to total flavin on storage Again, the flavin composition agrees with the figures of Massey and Swoboda but not with those of King *et al* [13] We suggest that the agreement in FAD to total flavin ratio between the two types of preparation after storage is fortuitous and should not be taken to indicate that the sample prepared at neutral *p*H had already broken down to this ratio in the course of preparation, as proposed by Massey and Swoboda[1] The higher initial total flavin and FAD content of acid precipitated samples might indicate, instead, the inclusion of flavoproteins which are not recovered in the alternative procedure and are not normal mitochondrial constituents

It remains to be determined whether the interesting breakdown observed by Massey and Swoboda is caused by labilization of a flavoprotein during exposure to acid *p*H or is the result of the precipitation of a labile flavoprotein at *p*H 5 4 but not at neutral *p*H In any event, these results do not support the conclusion of Massey and Swoboda regarding the absence of FMN in mitochondrial enzymes Their suggestion that the presence of FMN in dehydrogenases isolated from heart mitochondria is diagnostic of preparative modification is also not supported by these results and is, further, unnecessary to explain known facts The DPNH-cytochrome reductase preparations from heart described in the literature are, indeed, degraded derivatives of DPNH dehydrogenase, but they have been shown to arise during extraction and are thus not formed by whatever process is responsible for the labilization of FAD in certain preparations[6,7,14] As to DPNH dehydrogenase itself, recent work in this laboratory has conclusively demonstrated that the prosthetic group is FMN (ref 15), in agreement with predictions in the literature and analyses of its degradation products[5,6]

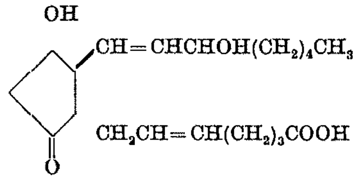
ISOLATION AND IDENTIFICATION OF TWO SMOOTH MUSCLE STIMULANTS FROM MENSTRUAL FLUID

By Dr G EGLINTON, Prof R A RAPHAEL, F.R.S, and Dr G N SMITH
Department of Chemistry, University of Glasgow
AND
Dr W. J HALL and Dr V R PICKLES
Department of Physiology, University of Sheffield

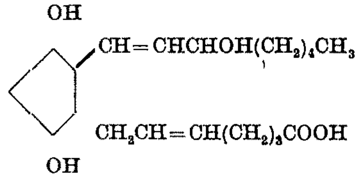
THE presence of a group of lipid smooth-muscle stimulants in menstrual fluid was first reported in *Nature* in 1957 (ref 1) Since then it has been shown that these substances, which are almost certainly produced by the endometrium in its secretory phase[2], are in part carried to the myometrium, and there stimulate the rhythmical contractions of normal menstruation. An excess of such an effect is probably an important factor in causing the intense uterine cramps of primary dysmenorrhœa[3]

Two physiologically active constituents of high potency have now been isolated from menstrual extracts and, by methods described here, have been identified as prostaglandins PGE_2 and $PGF_{2\alpha}$



PGE_2

(11a,15 dihydroxy-9-keto-prosta-5,13-dienoic acid)



PGF_{2a}

(9a,11a,15-trihydroxy-prosta-5,13-dienoi acid)

These substances are members of an important class of smooth-muscle stimulants originally detected by von Euler[4], who introduced the name 'prostaglandin', the recent outstanding investigations of Bergstrom and his colleagues have resulted in the separation and structural identification of five naturally occurring individuals of this closely related group of compounds[5,9,10,13,14]

The prostaglandins PGE_2 and PGF_{2a} are certainly not the only active constituents present in menstrual fluid, but they do account for the major part of the activity Although these two components are only present in minute amounts their high activity, detectable at a concentration of 10^{-10} g/ml, permitted the physiological effect to be discerned at an early stage[6]

Preliminary fractionation results gave some indication that the active materials were of the long-chain hydroxy-acid type[7] This result, together with the nature of the activity shown, gave the first inkling that the substances involved might be members of the prostaglandin series Accordingly, the separation techniques used so elegantly by Bergstrom's school in the isolation of the prostaglandins from more abundant sources were applied to the menstrual fluid derived from 3,675 specimens, collected and treated as described previously[7] Successive extractions with acetone and dichloromethane produced a crude menstrual lipid concentrate (about 75 g)

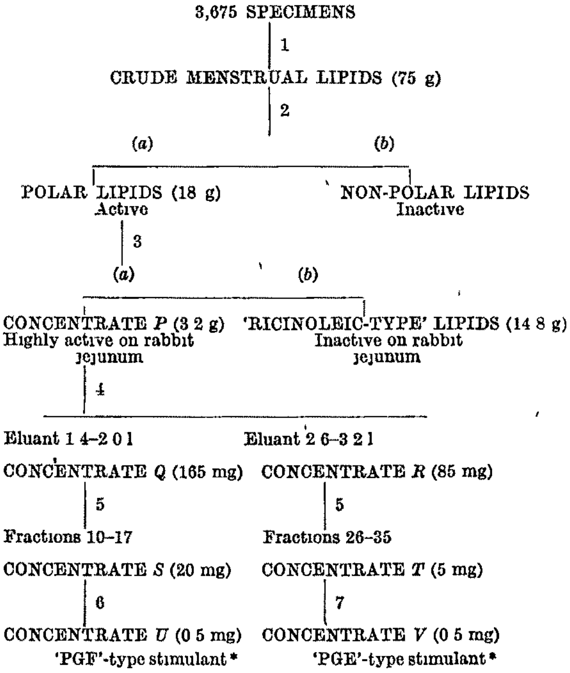


Fig 1 Fractionation scheme for the isolation of the active constituents from the menstrual specimens

(1) Acetone and dichloromethane extraction (ref 7) (2) Elution from hydrophobic 'Embacel' with (*a*) aqueous acetone, (*b*) acetone, ether (3) Reversed-phase partition chromatography on column of hydrophobic 'Embacel' impregnated with paraffin oil (ref 8) (*a*) 30 per cent aqueous acetone, (*b*) 50–100 per cent aqueous acetone (4) Reversed-phase partition chromatography using iso-octanol/chloroform//methanol/water, 1 1 9 10 v/v (see Fig 2) (5) Reversed-phase partition chromatography using iso-amyl acetate/chloroform/methanol/water, 4 6 35 65 (6) Reversed-phase chromatography using the system described in 4 except that a phosphate buffer of *p*H 7 2 replaced the water, followed by re-chromatography using system 4 (7) Extraction from chloroform solution with a phosphate buffer *p*H 7 2 followed by acidification and re-extraction into chloroform

* Biossay of the concentrates obtained at each stage on the guinea pig uterus and the rabbit jejunum indicated that the recovery of prostaglandin-like activity in the final concentrates was at least 90 per cent of that originally present

The treatment of this lipid concentrate is briefly outlined in Fig 1 Assay of the active constituents was carried out *in vitro* on preparations of guinea pig uterus human myometrium and rabbit jejunum Extraction of the polar lipids was followed by reversed-phase chromatography[8] to remove the compounds of 'ricinoleic acid type' polarity This produced a concentrate, *P* (3 2 g), containing all the components which were physiologically active on the rabbit jejunum Fractionation of *P* using Bergstrom's first system[9] (Fig 2) afforded two active fractions *Q* (165 mg) and *R* (85 mg) of contrasting physiological behaviour Fraction *Q*, a potent stimulant of the human myometrium (Fig 3), was highly active on the rabbit jejunum, but relatively inactive on the guinea pig uterus Fraction *R* either completely inhibited or feebly stimulated the contractions of the human myometrium (Fig 3), it was extremely active on the guinea pig uterus but only moderately stimulating to the rabbit jejunum

Separate fractionation of *Q* and *R* then followed using Bergstrom's second system[10], which is effective in discrimi-

Supplement to NATURE

No 4910 DECEMBER 7, 1963 Vol. 200

INSPIRATIONS OF ENRICO FERMI

The Collected Papers of Enrico Fermi
Vol 1 Italy, 1921–1938 Edited by E Amaldi, H L Anderson, E Persico, F Rassetti, C S Smith, A Wattenberg and E Segrè Pp xlii + 1043 (London and Chicago University of Chicago Press, Rome Accademia Nazionale dei Lincei, 1962) 15 00 dollars; 120*s*

"THERE can be no greater or more enduring monument to Enrico Fermi than his own work", and half that monument appears in Volume 1 of *The Collected Papers of Enrico Fermi*, which covers the period up to his departure from Italy to collect the Nobel Prize and non-return His papers were generally written in Italian in this period and are here reprinted without translation, but where he published the same paper in several languages the English text is given Because Fermi died at the relatively early age of fifty-three there are many contemporaries and collaborators who remember him well, and Volume 1 is probably unique in containing accounts of the circumstances which led to many of the investigations written by well-informed colleagues, and these are all in English Together with the long biographical introduction by Segrè, they make the whole volume most fascinating reading even without a knowledge of Italian

Fermi was a prodigy gifted with an exceptional memory so that he made rapid progress in mathematics and physics in his first university, Pisa, and had ample spare time to read widely, even in his third year he published original mathematical work on the effect of a gravitational field on electric charges A notebook written in undergraduate years shows with what very advanced topics he could deal with clarity and precision, and when even later in life he needed a powerful mathematical approach to a problem he could readily reconstruct it from his earlier achievements For his doctoral thesis, however, the subject had to be experimental, as theoretical physics was not an accepted subject in Italy in those days (1922) His colleague at Pisa, Rassetti, informs us that Fermi obviously enjoyed his first essays in experimental physics, which consisted of producing a curved crystal X-ray spectrometer which produced a focused image—no mean feat at that time

On returning to Rome he met Senator Corbino, the director of the Physics Institute, a man who gave the Fermi school such invaluable support at a later date Fermi's papers from Rome were theoretical, concerning gaseous phenomena, but after a year he was appointed to Florence, where he met Rassetti again and collaborated in experiments of some sophistication on the anomalous Zeeman effect in mercury vapour Fermi defined the experiment precisely and the two men successfully solved the problem under conditions of great physical hardship in the laboratory Rassetti recounts how Fermi as a theoretician was able to work at home burning the midnight oil and at this time produced very quickly his great paper on the theory of an ideal gas which would satisfy the Nernst principle at absolute zero and give the absolute entropy for low density and high temperature, the type of statistics used was developed at the same time by Dirac though Fermi's presentation to the Academy antedates Dirac's this paper won for him the chair at Rome in theoretical physics at the age of twenty-five and he was joined almost at once by Rassetti The "golden age of Fermi's life" had begun and modern physics in Rome was on the move

His work on the statistical distribution of electrons in an atom followed in 1927 that of Thomas in the Cavendish Laboratory, Cambridge, and at the Como conference on physics that year his contributions ranked with those of the great leaders of physics By 1928 his school in Rome had applied his statistics to a number of atomic problems which he reviewed in the Debye conference at Leipzig Segrè and Amaldi recount how smoothly he proceeded with complex calculations and taught the young school of theoreticians who were gathering around him, and in 1929 some of these went to laboratories outside Italy to strengthen their experimental activities, without these experiences the complex neutron research of later years in Rome would not have proceeded so well He continued theoretical work for three years on atomic and molecular problems and wrote the long review in *Revue of Modern Physics* 1922 on quantum theory of radiation known to all students of those days, but "the advent of quantum mechanics in Fermi's opinion signalled the completion of atomic physics the future lay in the exploration of the nucleus" (Segrè)

Segrè reminds us of the swiftly-moving events of 1932, unfortunately the Fermi review (paper No 72 of his works) on the nucleus presented to the fifth International Conference in Paris in July of that year is not reprinted in these collected papers, an error, in my opinion, in view of the volcanic upsurge which had just occurred Wertenstein confused the neutron just then born with the neutrino, a product of Pauli's hypothesis for β-ray decay but called by Pauli a "neutron", thereby unwittingly infringing Rutherford's 1920 name for a hypothetical particle of proton mass Fermi suggested the diminutive jokingly and it has remained for the β-decay particle from that day in October 1931 He worked on the β-decay theory and submitted an account to *Nature*, which was rejected as too remote from physical reality to be of interest to readers, so the full paper was published in Italy and has stood the test of time, alas, Fermi did not live to see a few neutrinos captured in thousands of gallons of water, the paper No 76 and fuller accounts are all reproduced

The young experimenters had returned to Rome and, with Rassetti, Fermi constructed nuclear instruments and prepared a strong polonium/beryllium neutron source Curie and Joliot had produced artificial radioactivity with α-particles, Fermi suggested using neutrons and almost instantly produced radioactive fluorine Rutherford was one of the first to congratulate him, and further to congratulate him "on your successful escape from the sphere of theoretical physics !" (one can see Rutherford made little sense of the β-decay theory !) Some difficulties were encountered with the experiments and Fermi decided to try filters made of paraffin wax instead of lead, strong activities were at once produced and in perplexity the experimenters went to lunch When they returned at 3 p m Fermi had the answer all worked out the fast neutrons had been slowed by collision with hydrogen atoms and were then more easily captured, thus raising the amount of artificial radioactivity produced by a very large factor Prof Corbino, who followed this work keenly, advised taking out a patent; this was instantly filed, the patent basic to the use of a moderator in a nuclear power reactor used on a massive scale in the huge reactors at Hanford, Washington, in 1944, for the production of uranium-239 which decays to plutonium, perhaps one of the most far-reaching patents of all time All the papers on neutron-induced radioactivity are reprinted, including the famous paper in the *Proceedings of the Royal Society* describing the enhanced effects of slow neutrons, and the suggestion that some of the activities of irradiated uranium samples might be due to "transuranic elements"

As Italy prepared for the Ethiopian war, the Rome school dispersed There followed a number of papers dealing with nuclear resonance levels, a tribute to Prof Corbino, and to Lord Rutherford "whose efforts had opened up one of the widest, and as yet unfathomable fields of investigation" (written 12 months before fission was discovered), and finally the Nobel Prize Address, December 10, 1938, after which Fermi sailed for the United States T E ALLIBONE

PLASMA PHYSICS AND RELATED TOPICS

Plasma Physics and Thermonuclear Research, Vol 2

Edited by C L Longmire, James L Tuck and W. B Thompson (Progress in Nuclear Energy, Series 11.) Pp viii+363 (London and New York. Pergamon Press, 1963) 100*s* net

THESE books on plasma physics consist of three text-books, two symposium reports and a review of plasma physics and thermonuclear research As is inevitable, since both the symposia and the review of thermonuclear research cover periods only up to the middle and end of 1961, much of the work arousing considerable interest at the present time is not included For example, in the review of plasma physics there is no mention of finite resistivity instabilities nor of the hybrid mirror containment systems of the Ioffe type However, these volumes enable some topics and papers, which would normally be scattered throughout the literature, to be brought together in such a way that a more uniform account of various aspects of the subject can be obtained Throughout all six books reference to the original contributions is facilitated by extremely extensive bibliographies

The text-books are respectively one of a fairly elementary nature, which could be used for an introductory course on magnetogasdynamics, an intermediate text giving an introduction to the dynamics of an idealized plasma, and an advanced text mainly concerned with the propagation of waves in anisotropic plasmas

Plasma Physics and Magnetofluidmechanics could be used as an introductory text for all interested in the dynamics of electrically conducting gases in the presence of applied electric and magnetic fields The subject-matter has a broad scope, but there is a distinct bias towards the engineering approach. Much of the early part of the book is an elementary review of the relevant electromagnetic theory, including a brief introduction to waves and wave propagation Properties of the ionized gas are then considered, including ionization and recombination, thermodynamics, and transport phenomena The flow equations of magnetofluidmechanics are obtained both from the Boltzmann equation and from a macroscopic point of view These lead to a discussion of Alfvèn and shock waves Various flow problems in the presence of magnetic fields, such as Couette and Poisseuille flow, are considered in detail and the results of these analyses are expressed in terms of a large number of similarity parameters The title is slightly misleading since there is no discussion of many of the usual problems of plasma physics, such as that of stability

A study of the dynamics of an idealized plasma in which inelastic processes (including ionization and recombination) are unimportant is presented in *An Introduction to Plasma Physics* Although intended as an introductory text some prior knowledge of both theoretical and plasma physics is essential, for at times the arguments in this book are difficult to follow This is possibly due to the large number of minor errors which are not always obvious and are sometimes misleading The whole book presents a very comprehensive account of plasma dynamics, and, since much of the material is not readily available elsewhere, it should be very useful in the understanding of specialized theoretical papers After introductory chapters, the book gives a full mathematical discussion of magnetohydrodynamics and magnetohydrodynamic stability The later chapters on plasma dynamics and particle motions, and the kinetic theory of plasmas, are by far the best and most fundamental Derivations are made of the Vlasov equation, the Fokker-Planck equation, and the magnetohydrodynamic equations, and there is included a good account of the dielectric properties of a hot plasma and an introduction to the concept of fluctuations

Magneto-sonic waves and low-frequency oscillations of a uniform magnetized plasma are dealt with in W B Thompson's book, but for a fuller account of waves and wave propagation one must recommend *An Introduction to Waves, Rays, and Radiation in Plasma Media*

This is an advanced text-book giving a very complete and unified treatment of the various factors which affect the propagation of waves, rays and radiation in anisotropic and inhomogeneous plasma media The fairly detailed mathematical formulation is of a mixed vector–tensor–matrix type, and throughout the basic physics is kept clearly in view There is a certain bias towards the propagation of electromagnetic waves and ionospheric application but a full account of other modes of propagation (such as magneto-elastic, magneto-acoustic, and shock waves) are included The latter are obtained from the magnetohydrodynamic equations, which incidentally are derived in detail Propagation is considered also in terms of a microscopic description for a low-density plasma obtained from the Boltzmann equation The sections on propagation of rays and radiation are almost self-contained The radiation considered is that due to collective motions in a homogeneous anisotropic plasma, bremsstrahlung and radiation characteristic of ionization processes are not included The section on ray propagation is probably the only such treatment conveniently available in text-book form

Some of the problems of wave phenomena are also considered in the *Proceedings of the Symposium on Electromagnetics and Fluid Dynamics of Gaseous Plasma* This is a collection of twenty-three papers presented in the

Microwave Research Institute Symposia Series in New York during April 4–6, 1961 This symposium brought together electromagneticists and fluidmechanicists to discuss topics of interest in the non-thermonuclear range On the theoretical side, attempts were made to unify the approach to plasma problems through both the moment equations akin to the macroscopic treatment of the fluid-dynamicists, and the microscopic treatment via the distribution functions and the Boltzmann equation There was some discussion on shock phenomena and magnetohydrodynamic channel flow The experimental studies included shocks, transmission and reflexion of microwaves and propagation properties concerned with communications problems, and the significance of plasmas for aerodynamic lift, thrust and drag To some extent the papers at this symposium had been condensed by their authors to such a degree that excessive reference has to be made to original contributions

This criticism cannot be made of the articles in *Plasma Hydromagnetics*, for each contribution tends to be self-contained In this book of the sixth Lockheed Symposium on Magnetohydrodynamics, held in December 1961, there are eight articles by prominent authors on diverse aspects, both theoretical and experimental, of the dynamics of plasmas These reviews are well presented and deserve a place on any plasma physicist's bookshelves

W B Thompson discusses particle interactions in a plasma and (using techniques of the same-type as those outlined in his book) calculates the electric microfield and afterwards obtains an expression for the scattering of radiation from a plasma This is extremely interesting in view of the scattering experiments using a laser which are being attempted at the present time R M Patrick and M Camac discuss an experimental investigation of collision-free shock waves in a magnetic annular shock-tube In view of charge-exchange effects, it is still not possible to say that the required dissipation in the shock is produced by non-linear interactions between magneto-hydrodynamic waves P A Sturrock is concerned with the energy and momentum associated with waves in plasmas R Lust reviews the application of plasma physics to problems in solar physics, and discusses the role of hydromagnetic waves in heating the solar chromosphere and corona R Karplus studies the absorption of low-frequency hydromagnetic waves in the lower ionosphere and related dispersion and dissipation phenomena leading to ionosphere heating In their article on hydromagnetic ionizing waves, W B Kunkel and R A Gross consider theoretical solutions for a magnetically driven ionizing shock propagating into an undisturbed magnetic field, and B Sonnerup deals with the theory of magneto-gasdynamic flow in slowly diverging two-dimensional channels in such a manner that compressibility effects are included Finally, R F Post gives a complete review of the nature of plasma instabilities which might be encountered in mirror machines, with the inclusion of a discussion of finite Larmor radius effects and some experimental results

Plasma Physics and Thermonuclear Research (Volume 2) contains, as the title indicates, reviews of work being carried out on controlled fusion The bulk of this book was prepared before the 1961 Salzburg Conference, and thus, in this case, the account by R F Post of the Mirror Machine Program (1958–1961) contains no mention of finite Larmor radius effects Other reviews on this volume are those on *OGRA*, the *DCX* Program, fast magnetic compression experiments, cusp containment, hard-core pinches and rotating plasma devices, together with articles on the problems of cyclotron radiation and acceleration of plasmas Since the first volume in this series was published in 1958, there has been some slowing down of the *tempo* of both theoretical and experimental investigations into confinement and other problems of thermonuclear research This volume is notable for indicating the increasing awareness of the difficulties of the thermonuclear problem, although some optimism (which still has not been rewarded) is shown Diagnostic techniques, too, have been considerably refined, for example, elegant continuum measurements have been made on *Scylla* using an X-ray crystal spectrometer

As a summary of the period 1958–1961 this volume cannot be improved, but since, in this case, most of this material (and much more besides) is now available in the proceedings of the 1961 Salzburg Conference (*Nuclear Fusion* 1962 *Supplement*), it is a pity that we had to wait until 1963 for this book J COOPER

A COMPENDIUM OF PHYSICS

American Institute of Physics Handbook

Edited by Dr. Dwight E Gray (Co-ordinating Editor) Pp xv+2118 Second edition (New York McGraw-Hill Book Company, Inc , London McGraw-Hill Publishing Company, Ltd , 1963) 231*s*

IN 1957 the American Institute of Physics brought out a 1,500-page *Physics Handbook*, and now, six years later, we are offered this second edition, enlarged by some 600 pages and brought very much up to date The first edition quickly established itself as a working reference and was highly appreciated by many engaged in research or in advanced teaching and by many preparing textbooks The content of a publication of this character can be reasonably judged on three grounds, namely reliability, coverage and accessibility Only time and detailed usage can reveal any errors in so formidably large a content The extent of the field covered is certainly very impressive, indeed no less than 127 authors have contributed to this compilation, which includes definitions, formulæ, tables and data in graphical form There are, however, undoubtedly some infelicities in this publication in connexion with the accessibility of the massive information packed between the covers

In this edition there are nine sections, one more than in the first edition, this dealing with solid-state, which also includes several items formerly dispersed within the other sections Despite the mere six years between the two editions this volume contains numerous changes, and not always additions Section 1 (computational), which formerly was merely a five-page list of available mathematical tables, has been expanded to a 56-page article describing and illustrating computors and their applications Section 2 (mechanics) remains largely as before, increasing slightly to 263 pp In the section on acoustics which follows, there is a marked reduction by 22 pp , to a total of 156 pp , largely through elimination of the former excessive 33-page section devoted to illustrations of impedance analogies This cut is a real improvement The section 4 on heat is doubled in length, now covering 330 pp , and a good deal of this arises through inclusion of tables for vapour-pressure and for heats of combustion Electricity and magnetism, in 291 pp , remains largely as before, although there are numerous changes in distribution of material and especially additions in connexion with magnetic properties of materials

The optics section is practically doubled now (239 pp) Many more refractive indices are included and a section on lasers is also incorporated The section entitled atomic and molecular physics, devoted very much to spectra, is covered in 229 pp and is very much as before Naturally enough, nuclear physics has expanded and now covers 326 pp The thoroughness of this section is illustrated by the fact that the list of accelerators in operation throughout the world is so detailed that this table alone fills 40 close-packed pages

The final new section, which is devoted to solid-state physics, occupies 160 pp In this there are extensive tables on crystallographic data, electrical properties of metals and semiconductors, extensive diffusion tables for ionic crystals and formidably detailed pages of references to original papers Included are compact sections on dislocations in crystals and on luminescence effects There is indeed a great deal in this new section

The book concludes with a 60-page index in which are perhaps some 6,000 items

The only real weaknesses in the volume are connected with indexing and with accessibility of information included One can indeed criticize several items The indexing is woefully inadequate For example, optical data of value are given in a table for 230 crystalline minerals, yet not a single one of the names of these minerals appears in the index, neither obscure minerals nor common minerals One might have hoped, as just one example, to find the name mica, or at least muscovite, somewhere in the index of a reference hand-book, but this is only one of hundreds of items, possibly thousands, which are missing Then again some real search difficulties arise through curious tabulation even of these very items just mentioned, for the minerals are arranged in order of increasing refractive index and not alphabetically This is a pure absurdity, in that it presupposes that a searcher already knows the refractive index of a mineral fairly closely when indeed he is seeking its value Not to have an alphabetical list of the minerals is an unforgivable oversight In any event, the separation of minerals into different tables for biaxials and uniaxials is no help, since this also implies previous knowledge of the optical character when beginning a search, no doubt a simple matter for a distinguished mineralogist, but certainly bewildering to a young research physicist

It is a matter for considerable regret that so magnificent a compilation of data should be marred by problems of accessibility The index should certainly be very greatly expanded in any future editions, which I very much hope will appear in due course As one has now come to expect from McGraw-Hill, the production of the volume is first rate both as regards format and typescript, diagrams and binding and the cost is by no means unduly high when account is taken of the formidable mass of content The initiative for the production of this valuable hand-book came from the American Institute of Physics, and the editor, D E Gray, is to be congratulated on a production which reflects a worthy sense of co-operation and team spirit This volume should be acquired by every physics laboratory whether devoted to research, to development or to teaching S TOLANSKY

AUTOMATIC CONTROL

Servomechanisms

By L A Stockdale Pp viii+295 (London Sir Isaac Pitman and Sons, Ltd, 1962) 35*s* net

Progress in Control Engineering

Vol 1 Edited by R H Macmillan, T J Higgins and P Naslin Pp viii+260 (London Heywood and Co, Ltd, 1962) 63*s* net

OF the many volumes that have appeared in the field of automatic control in recent years few have been written as, or been suitable for, student text-books The appearance of *Servomechanisms* helps to redress the balance in this respect, having been written specifically for technical college and university students by a practising teacher in the field

After a short introductory and non-mathematical chapter on the principles of control, three chapters are devoted to system 'hardware', including error detectors, motors and amplifiers System analysis commences at Chapter 5 with the Laplace method applied to second-order systems, followed by an early introduction to transfer functions These are used in the subsequent treatment of damping, phase-advance and integral compensation, and the effects of feedback and feedforward A chapter entitled "Transfer Function Analysis" includes the algebraic stability criteria and a brief mention of the root-locus method, making the valid point that computors and simulators are probably of greater value in designing for satisfactory response

Two chapters dealing with harmonic response and one describing the log-modulus method include analysis of the effect of phase advance and retarding circuits and a description of test equipment for these methods Three final chapters introduce the describing function and phase-plane methods for non-linear systems, and sampled-data systems

The content and arrangement of this book, which includes numerous examples at the end of each chapter, seem ideally suited for its purpose and deserve that it be widely used

Progress in Control Engineering is the first of a series of reviews of various aspects of the subject, similar to the reviews already appearing in several other fields Of the eight subjects treated four deal with general analytical methods while the others are concerned with more specialized topics In the first category are statistical methods (M. J Pelegrin), operational and transform techniques (B M Brown), time-lag systems (N H Chosky), and frequency response techniques applied to non-linear systems (P E W Grensted) Of the more specialized topics are "The Governing of Diesel Engines" (D B Welbourn), "The Human Operator in Control Instrumentation" (T B Sheridan), "Automatic Control by Pneumatics" (R Molle and J Rasquinet), and a contribution on the place of digital computors in control (M V Wilkes)

Each subject is developed from a point which demands very little in the way of specialized previous knowledge, and aims to bring the reader to the stage where he can "understand and appreciate both present-day work in the field and the lines along which future developments are to be expected" In the main the contributions achieve this objective, and this volume could well be the first of an interesting series E M DEELEY

CERAMICS AND THE 'HEAT BARRIER'

Special Ceramics 1962

Proceedings of a Symposium held by the British Ceramic Research Association Edited by P Popper Pp xiii+482 (London Academic Press, Inc (London), Ltd., New York Academic Press, Inc, 1963 Published for the British Ceramic Research Association) 105*s*

QUOTING from the cover to this volume "With the rise of new technologies and the quest for higher operating efficiencies at ever higher temperatures, the engineer looks to the ceramist to supply new, high-performance materials where metals or traditional ceramics fall short" This collection of papers, like its predecessor, *Special Ceramics*, published some three years ago, includes a number by authors of international repute There are 25 papers in all, an increase of 20 per cent compared with the previous volume, and there was also a similar increase in the attendance at the symposium, reflecting the growing interest in these new and challenging fields

The topics fall broadly into the following groups preparation and properties of refractory non-oxides and of beryllium oxide, pyrolytic deposits, measurements; techniques; applications The materials covered are mostly non-oxides, but a few oxides, in particular those of beryllium, aluminium and titanium, are included Measurements include rapid methods of determining thermal expansion and thermal conductivity Among the techniques are powder compaction, reaction sintering, hot pressing, as well as pyrolysis Applications include high-temperature nuclear fuels, moderators, etc, parts for rocket motors, protective coatings for refractories, oriented graphite susceptors for use up to 3,400° C, particle accelerators, high-power microwave absorbing elements, super-refractories for magneto-hydrodynamic power generators, and ceramic-to-metal seals for atomic energy applications

The book is excellently produced and the text is well illustrated The wealth of new material presented will commend it primarily to the specialist However, due in great measure to the care with which the contributions to the symposium have been transcribed and edited, most of the text will be found very readable, even by the non-specialist, who could well draw inspiration from the ingenuity brought to bear on some of the problems encountered. For example, the use of (very rapid) 'plunge sintering' in order to utilize the heat of an exothermic reaction for sintering uranium monocarbide, and again, the elegant method used to avoid contamination during the nitriding of aluminium, by levitating the latter in a radiofrequency field There are, of course, numerous points of fundamental significance, to name but two—rate-determining processes in sintering, and the filamentary, electrically conducting paths observed in rutile, apparently related to the time-dependence of conductivity in the unique crystal direction B E WAYE

COMETS

The Nature of Comets

By Dr Nikolaus B Richter. Translated and revised edition by Dr Arthur Beer. With an Introduction and Additional Contributions by Dr R. A Lyttleton Pp. xli + 221 (London. Methuen and Co , Ltd., 1963) 63*s* net.

IN 1954, J. A Bath of Leipzig published *Statistik und Physik der Kometen* by Dr N B. Richter. The monograph summarized the main observational and theoretical features of the nature and behaviour of comets and did much to stimulate interest in a rather neglected field of enquiry. Since then cometary investigations have acquired greater importance, due in part to the rapid development of space research and also to the interest aroused by the appearance of Comet 1957 III Arend–Roland and Comet 1957 V Mrkos

In this, the first English edition of Richter's monograph, the original text has been brought up to date by extensive revision and the addition of new material Further, it contains a challenging introduction by Dr R A Lyttleton, well known in cometary astronomy for his accretion theory of the structure and origin of comets In this, Lyttleton presents his personal views and criticisms of the present state of cometary theory He makes it clear that he does not agree with all the conclusions of Richter, Oort and Whipple According to Richter, almost the entire mass of a comet resides in its comparatively small nucleus, which consists of solid material ranging from dust particles to chunks of meteoritic size As the nucleus approaches close to the Sun, solar radiation causes it to emit gases These gases form the coma, while radiation pressure and corpuscular radiation drive out the cometary tail. Lyttleton, however, remarks that once the existence of large chunks of rock is postulated it becomes necessary to explain why none of them ever get into meteor streams. During a rich meteor shower, millions of small meteors are injected into the Earth's atmosphere, but so far without a single large object of meteoritic proportion coming in at the same time on the same path He also considers that Richter's analysis amounts to convincing proof of the inadequacy of solar heating to account for the great longevity of certain large tail-producing comets

According to Oort the Sun is encompassed by a very distant spherically distributed swarm of comets On the very rare occasions when stars pass sufficiently close to the shell they perturb a comet so that it leaves the shell, falls towards the Sun, and becomes visible from the Earth. So rarely does this happen to a single individual comet that to meet the observed actual supply some 10^{11} comets are assumed to reside in the shell. Lyttleton considers that the hypothesis of the cometary shell is valueless It cannot (as yet) be verified by observation; does not serve to correlate observations, in no way explains the origin of comets, and thus provides no clues whatever as to their structure Whipple's theory has similar limitations It postulates a cometary nucleus in the form of a conglomerate of ices and meteoritic particles Under the action of the Sun's heat volatile compounds in the ices are evaporated and sufficiently irradiated to exhibit the emission lines observed in cometary spectra Lyttleton claims that both theories are merely speculative descriptive schemes which have no foundation for their hypotheses in either established astronomical fact or attested theory The way in which he arrives at this conclusion and then resolves certain objections levelled against the accretion theory shows a nice appreciation of the value and importance of the principles of scientific method

After giving a short account of the historical development of cometary research, Richter proceeds to describe statistical results regarding orbital forms, inclinations and aphelion distances, the perturbations produced by Jupiter, the 'capture hypothesis', comets with planetary orbits and comet groups Section 3 deals with the structure of comets, that is, with the progress made in determining the dimensions, masses, densities and nature of cometary nuclei, heads and tails Section 4 is of particular interest since it gives a preliminary summary of the work done on the two bright comets of 1957 Both objects were subjected to extensive photometric, polarimetric and spectrographic observations Richter's discussion of the available material helps towards clarifying the problems opened up in the last four sections, namely comets as processes of cosmic decay, the origin and formation of comets, cometary problems for future research work; a typical model of a comet A number of valuable cometary tables, a generous bibliography and adequate name and subject indexes complete the monograph Dr A Beer has made an excellent job of the translation The text reads well and is embellished with a well-chosen set of reproductions of photographs of comets A book so interesting and informative deserves the widest possible readership It may not achieve this, but it will, at least be read with pleasure and profit by all astronomers, professional and amateur alike H C KING

THEORY OF ELECTRICAL MACHINES

Electric Machine Analysis using Matrices

By Dr W J Gibbs Pp vii + 70 (London Sir Isaac Pitman and Sons, Ltd , 1962) 17*s* 6*d* net.

METHODS of analysis for the investigation of the behaviour of electrical machines began to be developed in the 1880's For alternating current machines the technique of the vector diagram, the equivalent circuit and the utilization of complex numbers in circuit analysis achieved universal application in the first two decades of the present century. Each type of machine was analysed individually.

What is now termed the 'generalized theory of electrical machines' has been developed during the past thirty years Expressed in terms of the basic equations of an idealized machine and utilizing matrix or tensor methods for their manipulation, it is possible to establish a general theory of electrical machines which will comprehend the behaviour of practically all types of machine under all conditions of operation This unified theory was propounded and developed by Gabriel Kron It is with this subject that Dr Gibbs's book deals

The book aims to present the mathematical basis of the theory as simply and clearly as possible A short introductory chapter describes the purpose of the generalized analysis, its limitations and its method of approach Chapters 2 and 3, entitled, respectively, "The Fundamental Machine" and "Two-Axis Theory", comprise the setting up of the machine equations in terms of the basic two-phase system and the development of the transformations for two-axis representation In these two chapters, in the course of developing and manipulating the equations, the notation of matrices and certain matrix operations are introduced

The next two chapters deal with transient and sub-transient conditions and with the setting up of the torque equations and, in the latter connexion, the rules of matrix multiplication are more fully exemplified It is at this point that the analysis of machines of different types is taken up, direct current machines, induction motors and general commutator machines forming the subjects of individual chapters The treatment is completed by a chapter dealing with small oscillations

The book concludes with a short chapter entitled "Tensors" in which the author describes the relationship of electrical machine theory to differential geometry, the absolute differential calculus and to tensor calculus

No prior knowledge of matrix theory is assumed The requisite rules of operation are developed as required and their utility and validity demonstrated by appropriate examples The most important fundamental concept of the "connection matrix" is introduced in the simple example of the d c series machine and is then more fully developed in relation to a c machines The author states at the outset that, "The true concepts behind the two-axis theory are mathematical and for that reason the mathematical treatment in this book is less complicated and more satisfying than the usual physical approach" This claim can, in large measure, be sustained The theory is developed in a clear, logical and systematic fashion and constitutes an excellent introduction to the subject. None the less, physical conditions viewed along with mathematical development can illuminate the subject and, by adding realism, carry conviction The basic concepts which underlie two-axis theory could with advantage have been illustrated from the physical point of view

Dr Gibbs has arranged his presentation of the subject so as to lead into the important topics with a minimum of digression, and he has succeeded in developing with remarkable economy and clarity the principles of the subject to a point at which the reader can enter the more general literature of the field To a reader with a background knowledge of the conventional theory of electrical machines the treatment is admirably suited In particular the book will serve well the needs of teachers of undergraduate courses dealing with electrical machines, and of students in the final year of such courses J Greig

A RUSSIAN VIEW OF EARTH HISTORY

Basic Problems in Geotectonics

By V V Beloussov Edited by John C Maxwell Translated by Paul T Broneer (International Series in the Earth Sciences) Pp xvi+809 (New York McGraw-Hill Book Company, Inc , London McGraw-Hill Publishing Company, Ltd , 1962) 108*s* 6*d*

Basic Problems in Geotectonics is a monumental synthesis of Earth structure in which Dr Beloussov presents what he believes to be the main outcome of geotectonic research in the U S S R since the Revolution The subject has long been a controversial one, and some of the facts and theories presented in this book are likely to be disputed by many workers in this field

After a preliminary summary of the history of development of geotectonics there follow an outline of the internal structure of the Earth and a discussion of its origin The classification of structural forms observed in rocks exposed at the surface is both novel and stimulating The following section on present and past vertical oscillatory movements is an important one, as these observations form the basis of his main thesis The maps and sections which illustrate the variations in facies and thicknesses of Palæozoic and Mesozoic formations in Central and Western Russia should prove to be of particular interest to workers outside the U S S R , as they give a clear summary of detailed work not always easily accessible in this form The next section discusses the theories of formation of folds and faults, and the last two parts present Dr Beloussov's views on the processes which have led to the arrangement of the larger structural units

Dr Beloussov is very critical of the idea that orogenic belts are developed in regions of large horizontal displacement, although he does find it difficult to see how vertical movements alone can lead to the development of mountain chains where the rocks have been tightly folded and apparently strongly compressed His belief in the prime importance of vertical movements leads him to assume that our knowledge of linear fold zones is totally inadequate and probably fundamentally incorrect He suggests that the folding in the Appalachian Mountain chain has been incorrectly interpreted, and that the greater part of the nappe structure of the European Alpine chain is geometric speculation and, to use one of his favourite and frequent criticisms, "formalistically unsound" The notion that all fold belts are developed on the plan of the Alpine model could certainly be criticized, but Dr Beloussov's denial of the accepted structural geometry of the Alps seems scientifically irresponsible For example, no Alpine geologist would dispute that the Prealpine nappes have been displaced horizontally at least 60 km, not, as Beloussov suggests, a mere 11 km He explains the formation of linear fold belts by vertical movements on long and deep fundamental flaws in the crust Vertical movements on these faults lead to the stretching of the sedimentary cover, and a later reversed movement of the fault-block causes the previously stretched beds to become shortened and folded as they settle back into their original position

Dr Beloussov believes that the deep ocean basins represent regions of subsidence formed as the result of a process of basification or "basaltization" of a relatively homogeneous granitic crust in comparatively recent geological time

This is a book which all interested in Earth structure should read, for in it the evidence supporting the theory of oscillatory vertical movements of the crust is fairly fully documented It should stimulate the reader to re-examine many of the generally accepted facts and theories, although Dr Beloussov's partisan approach to Earth science might be found to be somewhat exasperating J G Ramsay

THE HALLEY BAY EXPEDITION OF THE ROYAL SOCIETY

The Royal Society International Geophysical Year Antarctic Expedition

Halley Bay, Coats Land, Falkland Islands Dependencies, 1955–59 General Editor Sir David Brunt Vol. 2 Radio Astronomy, Ionospheric Physics Pp xv+289+14 plates Vol 3 Seismology, Meteorology Pp. xvii+382+5 plates (London The Royal Society, 1962) 140*s* , 23 dollars per volume

Right from the inception of its International Geophysical Year Antarctic Expedition it has been one of the aims of the Royal Society that the results should be available promptly, particularly in view of the pace of present-day developments in geophysics. It is a considerable achievement that three volumes, containing extensive tables of the essential data obtained, as well as careful analyses of the material available, should have been published so soon after the close of the International Geophysical Year (see *Nature*, 192, 1004 (1961) for review of Volume 1). The present review of Volumes 2 and 3 can give no more than a bare outline of the considerable results achieved.

Volume 2 deals with radio astronomy and ionospheric physics. The report on radio astronomy is presented in two sections. The first section, by P. M. Brenan, deals with observations of radio-star scintillation, using a radio-source in Centaurus, a careful study has been made *inter alia* of the height of the diffracting screen to which the scintillations are attributable, the drift velocities of the ionospheric irregularities causing scintillation, the seasonal and diurnal variations, and the size and shape of the ionospheric irregularities. The overall conclusions are that the height of the diffracting screen is below 1,100 km and probably below 500 km, and that the irregularities, which are steeply inclined to the horizontal, are of width 2.4 km and of length greater than 120 km, the irregular screen at Halley Bay presumably forms a broad band between the *E* and *F* regions at altitudes between approximately 100 km and 200 km. The second section of the radio-astronomy report, by D. P. Harrison, describes radio-echo observations of auroræ and meteors. The difficulties of operating the equipment at Halley Bay were successfully overcome, and, in fact, Halley Bay proved to be a particularly suitable site for observation. A critical discussion is given of the results of the radio-echo data, and tables of indices and counts, arranged chronologically, describe the levels of auroral and meteor activity.

The report in Volume 2 on ionospheric physics, by W. H. Bellchambers, L. W. Barclay, D. L. M. Cansfield and W. R. Piggott, describes the Halley Bay equipment for radio-wave measurements of the ionosphere, and gives a detailed discussion of the experiments, these were planned to provide: (*a*) ionograms showing the relations between the frequency of the radio-waves and the equivalent heights from which they were reflected; (*b*) measures of the absorption suffered in the ionosphere by radio-waves of frequency 2.2 and 4.0 Mc/s, (*c*) measures of the horizontal drift velocity of local irregularities in the reflecting layers of the *E* and *F* regions. Extensive tables are given of the values of the parameters found by analysis of the records. This report, like the preceding one, is well illustrated by plates and diagrams.

Volume 3 is concerned with seismology and meteorology. The seismological report, by J. MacDowall and Mrs. E. M. Lee, is based on the records of a three-component Willmore seismograph installation, built on a floating ice-shelf, this might be thought to be a most unsuitable location for a seismological observatory, but the decision was amply justified by the results obtained. The Synchronome clock of the observatory was rated by vernier time-signals from Canberra, the identification of phases on the records was greatly facilitated by use of the preliminary epicentres, furnished by courtesy of the U.S. Coast and Geodetic Survey from Washington, D.C., via McMurdo Sound, Mawson and Vestfold Hills. The report contains two bulletins of readings of earthquake phases. The first bulletin contains the readings made by MacDowall at Halley Bay and telegraphed monthly to the Royal Society for transmission to World Data Centres, after the return of the expedition, these readings were checked and supplemented where necessary by Mrs. Lee. A new set of readings from the seismographs was then made independently of any epicentral information, the additional phases thus disclosed have been listed in a separate bulletin.

The greater part of Volume 3 constitutes the meteorological report. As Sir Graham Sutton remarks in the preface, "In many ways, Antarctica is the ideal laboratory for geophysical investigations and offers to the meteorologist unique opportunities to study an atmosphere which is completely free from man-made influences". Of the great mass of meteorological information secured, it must suffice to mention here the general headings, such as the "total ozone observations" and the determinations of ozone concentration near the surface of the ice-shelf made by J. MacDowall. In addition, ozone soundings by ozone-sonde were made by J. MacDowall and J. A. Smith, 19 ascents were carried out, of which 16 were successful, and graphs have been constructed showing the variation of ozone concentration with height up to the limits reached (generally about 20 km). This ozone programme is a valuable addition to our store of information.

Observations of short-wave radiation of the Sun and sky were carried out by J. MacDowall and D. T. Tribble, using two solarimeters, and the radiation balance was recorded by a ventilated radiometer. Tables are given of the total solar radiation, the diffuse solar radiation and the net flux of radiation for each day. A section on upper-air meteorological observations, by J. MacDowall and J. M. C. Burton, describes the results of radio-sonde and radar methods of determining upper-air temperature, pressure, humidity and wind velocity. A twice-daily programme of ascents (nearly 1,000 ascents in all) was carried through, and the data for each of the separate ascents have been listed for surface level, standard levels, significant levels, tropopauses and bursts. The analysis of this large body of observations was effected by transferring all the data to 'Hollerith' cards at Halley Bay and afterwards sorting these cards on 'Hollerith' machines at the Meteorological Office.

In these two volumes the high standards of printing and arrangement of Volume 1 have been maintained. An excellent feature is the reprinting, at the beginning of both volumes, of Sir David Brunt's narrative account of the history of the expedition as given in Volume 1. The exposition of the theory, the observations and their analysis is so well balanced for each of the disciplines involved that the volumes should become standard works of reference rather than mere catalogues of observations. The Royal Society and the authors are to be congratulated on this considerable addition to geophysical knowledge.

R. STONELEY

A GREAT SCIENTIFIC ENTERPRISE

Discovery II in the Antarctic

The Story of British Research in the Southern Seas. By John Coleman-Cooke. Pp. 255 + 50 photographs. (London: Odhams Press, Ltd., 1963.) 25*s*.

THE once remote and uninhabited Antarctic is now within a week's air travel from Europe and has many permanent scientific stations, at least one of them the size of a small town. This dramatic change has come about since the end of the Second World War, and is due to the territorial, economic and scientific ambitions of many nations. Prior to the First World War, knowledge of the Antarctic was obtained from the results of various exploring and research expeditions. Between the Wars some similar expeditions were sent out, but a new phase of Antarctic investigations began in 1923 when the *Discovery* Committee started the continuous series of researches that are still in progress. The foundation of this unparalleled programme of investigations was laid by the late Dr. Stanley Kemp, a brilliant scientist and charming character, whose memory is held in high affection by all who had the privilege of serving under him.

The *Discovery* investigations were intended to carry out research on the biology of whales so that accurate knowledge could be brought to the framing of legislation for the protection of the very valuable whaling industry in which over-exploitation threatened ruin similar to that which had overtaken the Arctic whale fishery in the previous century The knowledge was obtained and international agreements were made—but all was in vain, for bureaucrats under pressure from big business are ever weak, and the regulations they made were weak The Antarctic whales are reduced to a vestige of their former abundance and the industry is dying, nearly all the great whaling enterprises have left the business, which is now carried on mainly by Russia and Japan, the newcomers to the Antarctic

In planning the *Discovery* research programmes, Kemp saw that any useful investigation into the biology of whales required a comprehensive examination of their ecology and environment The *Discovery Reports*, which have now reached their thirty-third volume, show the wide fields covered as a result of his foresight, ranging from oceanography and geology to whales, plankton, fishes, seals and birds Although the *Discovery* investigations have not saved the whaling industry, they have provided such an enormous mass of scientific information that as much, probably more, is now known about the circumpolar Antarctic Ocean as about any of the seas

The *Discovery* investigations have been carried out at the marine research station set up on the Island of South Georgia, and with four ships, the *Discovery*, a wooden barque-rigged sailing ship (1924–27), the smaller *William Scoresby* (1926–51), the *Discovery II* (1929–60), later transferred to the National Institute of Oceanography, and the *Discovery* (1963→), the Institute's splendid new research ship

This book gives a general account and history of the *Discovery* investigations, the men who undertook them, the work they did, and the adventures that befell them It also gives some account of the scientific results, presented in a non-technical way for the layman, but it is essentially the story of the field work of the investigations from their beginning to the present, gathered from official and other reports, and especially from conversation with those who took part in them It is difficult for a former member of the *Discovery* Expedition staff to review this book objectively, to a young man the impact of the Antarctic, and the day-to-day experiences of an expedition such as the *Discovery's* in the early days of the investigations nearly forty years ago, were so great as to have formed a delightful background for the rest of his life Putting emotion on one side, however, I can say that the author has successfully caught the spirit of the *Discovery*, and gives a very interesting narrative of the expeditions and their results The book is well illustrated with photographs

L HARRISON MATTHEWS

THE BRACHIOPODA

On the Morphology and Classification of the Brachiopod Suborder Chonetoidea

By Dr Helen M Muir-Wood Pp viii+132+16 plates (London British Museum (Natural History), 1962) 110*s* net

PALÆONTOLOGISTS, who are concerned about the future of systematics, have recently been taking a more critical look at the supra-generic contents of the taxonomic hierarchies that interest them This re-appraisal has undoubtedly derived a great deal of impetus from the present preparation of treatises on palæontology in France, the U S S R and the United States But it also probably reflects an uneasy awareness that classical taxonomic procedures, which have served palæontologists so well in the past, are now being tested by modern biological concepts of speciation and increasing access to computors with the concomitant promise or threat, as the reaction may be, of numerically contrived classifications In effect, the taxonomic pyramids that have been so elaborately built up over the years are now being re-surveyed in order to find out what differences these new methods of construction are likely to have, and although total demolition may ultimately prove to be necessary, this critical examination must go on Such surveys inevitably vary greatly in the quality of their findings, but the best are indisputably those that weigh all evidence against the healthy scepticism of experience and Dr Muir-Wood's study of the morphology and classification of the chonetoid brachiopods is an admirable example of this balanced approach

As an introduction to her monograph, Dr Muir-Wood gives a general account of chonetacean morphology and explores the anatomical, evolutionary and ecological implications of those features peculiar to the group These sections are as comprehensive as one would wish, but different interpretations do spring to mind Has she, for example, paid enough attention to the generalized nature of chonetacean morphology ? Ignoring the hinge-spines, the most striking aspect of the earliest chonetaceans, like *Strophochonetes* and *Protochonetes*, is their unspecialized internal morphology, which is so reminiscent of many young strophomenacean and plectambonitacean shells that the development of the cardinal process, rather than the arrangement of the muscle fields or the absence of dental lamellæ, may ultimately prove to be more diagnostic of group affinity It is also controversial to infer that productoid spines were "open at the distal end" and were, therefore, unlike the chonetacean hinge-spines Apart from differences in their distribution, no detail of shell structure suggests that they were anything but identical in origin, development and function

The systematic descriptions of the genera have been compiled with all the authority that Dr Muir-Wood's experience commands They make the monograph one of the most complete reviews of a major group of the Brachiopoda ever attempted, with a nicely balanced diagnosis for each genus together with a list of all the species it embraces, its geological range and geographical distribution, and it is not surprising to find that her carefully considered judgments have led to the recognition of seven new genera Indeed, the only doubts that linger about the systematic treatment generally are the desirability of so many sub-families Thus the distinctions drawn among the four sub-families comprising the Daviesiellidae do not seem to be more important than the variation tolerated within, for example, the Anopliinae But such differences of opinion simply illustrate the way in which personal taste still pervades palæontological practices, and one can only summarize the impact of the entire study by declaring that students of the brachiopod phylum will be indebted to Dr Muir-Wood for a long time to come for preparing such an invaluable monograph

ALWYN WILLIAMS

FIBRE CHEMISTRY

Textile Chemistry

Vol. 1 The Chemistry of Fibres By Prof R H Peters Pp xiii+477 (Amsterdam, London and New York Elsevier Publishing Company, 1963) 75*s*

PROF PETERS has attempted a most comprehensive work He has concentrated almost the whole science of fibre structure into a treatise of some 450 pages After a general introduction in which he classifies polymers, he proceeds to a detailed investigation of the chemistry and physics of the man-made fibrous polymers Then follow chapters on condensation polymers, addition polymers and copolymers Here one notices the variability of the level of treatment of the subject, but later, when dealing with the natural materials, this variation becomes very obvious If one considers his work on the kinetics of polymerization, the mathematical derivations of many of the equations used in the physical studies of chain-length, distribution and the kinetics of polymerization are set out in most cases as a mathematical exercise It might well be that this could have formed a more mathematical monograph on these known aspects of polymer structure In this case the derivation of the formulæ could have been curtailed in the present work, and the physical significance of the results to the understanding of polymer structure given greater emphasis It should, however, be pointed out that the references in this field are good The chapter on molecular weight determination has two pages devoted to chemical methods and about twenty to a detailed description of physical methods

Chapter 6, Chapter 10 and Chapter 11 give comparatively simple descriptions of cellulose, proteins (mainly wool) and silk fibres respectively Other chapters then deal with the physics and chemistry of these materials, and this treatment of the subjects shows wide variations in levels of presentation This is particularly so on p 194 *et seq* , where an advanced treatment of the reactions of the hydroxyl groups in cellulose is given I feel that, in this work, accessibility of the glucose residue with special reference to crystalline packing should be considered in any theory applicable to cellulose fibres Chapter 9 describes the work which has been done on synthetic polypeptides, but for students it might have been a help to correlate the natural and synthetic α- and β-structures even if the treatment had been critical of some of the theories advanced

Chapter 12 is devoted to the crystalline structure of polymers, and there is no doubt that a re-editing of this chapter should be done It must be pointed out that many of the X-ray diagrams are incorrectly aligned (this can be readily corrected by an arrow giving the fibre axis) and the text of pp 321 *et seq* has been confused Fig. 77*a* is wrongly oriented but correctly labelled, Fig 77*b* is not ramie but most likely polyvinyl alcohol or a similar vinyl fibre Figs 77*c* and 77*d* are incorrectly oriented Fig 77*e* is most likely a polyacrylic fibre with a TiO_2 dilustrant included, and Fig 77*f* is an incorrectly oriented picture of ramie taken on a circular camera and contains no TiO_2

Chapters 13 and 14 are good generally, the former on melting and crystallization of man-made polymers, and the latter on accessibility and crystallinity The chapters on fibre extrusion should probably have included the equations of extrusion This would then have clarified the statement on p 432, which suggests that yarn diameter (presumably denier) on extrusion is a function of the diameter of the jet holes Probably the main criticism of this work is that Prof Peters has attempted to cover too wide a field and in doing so has, maybe of necessity, had to vary the standard of treatment of his material. The scope, however, is good, and there is nothing in the book that could not be rectified by a good re-editing

F. Happey

QUANTITATIVE ORGANIC ANALYSIS

Quantitative Organic Analysis via Functional Groups

By Dr Sidney Siggia Third edition Pp xii + 697. (New York and London: John Wiley and Sons, Inc , 1963) 145*s*

THE third edition of Dr. Siggia's book is described on the dust-jacket as being about double the size of the previous edition The price of the book has been almost quadrupled Neither increase would have been entirely necessary had the author been a little more selective in his choice of material The book consists largely of reprints or partial reprints of papers and articles from other books and journals The sources are quite clearly indicated and the extracts are variously described as being, reprinted with permission, reprinted in part, reprinted, adapted or adopted or are simply referred to Some of the papers are Dr Siggia's own, but his main role has been that of a collector and he has drawn heavily on the American Chemical Society publication, *Analytical Chemistry* Simple reference to the original journals would have sufficed for much of the original discussion, results, tables and diagrams Only the essential analytical procedure need have been retained in full Applied throughout the book this would have reduced the size, lowered the price and in all probability increased the sales

The book is so planned as to devote one chapter to the methods of analysis for each functional group considered These include hydroxyl and carbonyl groups, carboxylic acids and derivatives, alkoxyl and epoxide groups, peroxides, unsaturation, acetate, ketals, amino and imino groups, hydrazides, diazonium salts, quaternary ammonium compounds, isocyanates and isothiocyanates, sulphides, sulphoxides and sulphonic acids and derivatives

Each section is preceded by a discussion of the particular chemical reactions involved in the determination and this is followed by the methods derived from them Methods are laid out in standard fashion indicating apparatus and reagent requirements followed by procedure and calculation All the methods chosen have been tried in the author's laboratory

At the end of the book there are chapters dealing with the development of new analytical methods, the role of quantitative functional group determination in the identification of organic compounds, the use of differential rate of reaction to analyse mixtures and the weighing of volatile and corrosive liquids The chapter on the role of quantitative functional analysis might well have come first rather than almost last, while that on weighing corrosive liquids, although useful, would have been better had it been enlarged to deal with sampling and sample-handling techniques in general The analyses of mixtures by differential rate of reaction is illustrated by reference to mixtures of alcohols, amines, esters, etc , good results being obtained in some instances

The section on physical methods of analysis has been excluded from this edition In view of the importance of these methods in modern organic analysis, not only should it have been retained, but also it should have been enlarged

This book is not likely to recommend itself to students because of its high cost It may be useful, however, to those laboratories engaged in general quantitative organic chemistry where library facilities are limited

P J Cooper

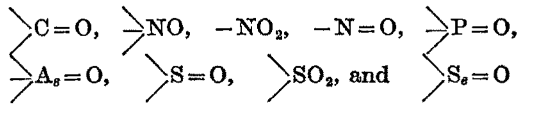
OXO-COMPOUNDS

Inorganic Adduct Molecules of Oxo-Compounds

By Ingvar Lindqvist (Anorganische und Allgemeine Chemie in Einzeldarstellungen, Band 4) Pp vi + 129. (Berlin Springer-Verlag, 1963) 20 D M

AT first sight this book appears to be something midway between a review article and a section of Gmelin Resemblance to the latter owes much to the style of printing, which makes for extremely tedious reading

The book is concerned with adducts formed by Lewis bases in which the donor atom is oxygen, but it is limited to a discussion of so-called 'oxo' donors in which the oxygen atom is linked to only one other atom These donors include molecules containing the following groupings



Donors such as ethers are not included, however

The text opens with a brief discussion of the conditions for adduct formation, followed by a short review of the characteristic co-ordination numbers This review is surprising in that under the heading "Transition Elements" it includes only the elements manganese, iron, cobalt, and nickel, the other elements, which (to British chemists at least) are commonly considered as transition elements, are grouped with the characteristic elements which show the same maximum oxidation state (for example, titanium and zirconium are grouped with germanium and tin) This review is not up to date, since it says nothing of the recent work on higher co-ordination numbers of a number of these elements It is well known, for example, that zirconium can exhibit a co-ordination number of eight, and recently X-ray work has confirmed a similar state of affairs for titanium in its diarsine complex.

Quite a long section follows in which the various known adducts are listed together with original references This is done systematically for each of the donor types. Although this section is mainly just a list of compounds, several useful observations are made at various points, and workers in the general field of co-ordination chemistry will find the references to be almost complete It is disappointing, however, to find that the majority of the 1962 references refer to unpublished information, and this suggests that there has been quite a long delay between the preparation of the manuscript and the appearance of the book.

Various topics are then dealt with. These include a discussion of the physical methods used for the study of molecular adducts, a review of the available structural data, and the catalytic activity of acceptor molecules

The final section of the book discusses "A Theory For Donor-acceptor Interaction with Oxo-compounds", and here the author deliberately sets out to give a very elementary account of the bonding in adducts He is evidently very unhappy about most of the recent developments in theoretical chemistry, since he refers to quantitative theories being "no more than empirical or at best semi-empirical rationalizations couched in a jargon which hides our actual ignorance" Accordingly, he discusses theoretical aspects of the bonding in adducts in a very elementary manner I found this section very tedious and uninspired, and in places naive The discussion on the amount of π-bonding in $M=O$ bonds (p 92) is particularly unfortunate, it is a pity that the author does not quote Van Wazer's recent work in the $P=O$ field, for example

Summing up, it can be said that this book has the appearance of an expanded review article, and that it has suffered by the expansion It is written in a reasonable style, however, and it is only in one or two cases that misuse of English leads to confusion I found very few misprints The book will be of some use to research workers in the field of molecular adducts, but it is unlikely to be of interest to general readers

G W A FOWLES

INTRODUCING ORGANIC CHEMISTRY

Organic Chemistry

By Dr D J Waddington Pp x+442 (London Mills and Boon, Ltd, 1962) 22s 6d

DR WADDINGTON'S book aims to cover requirements for the Advanced Level Examination for the General Certificate of Education, first M B and university entrance scholarships Small print is used to denote parts which the less-advanced candidates may omit Despite this I feel that most students making a start on organic chemistry would be better served by a smaller introductory book Afterwards this would be excellent, the brightest ones might start with it The type, line diagrams and formulæ are very clear and the price reasonable for the size of book

Two short chapters deal with the nature of organic chemistry and compounds, and with general manipulative technique Forty-three chapters follow In most cases each deals with one homologous series or with a small group of related series, but special chapters are included to cover atomic structure, valency, and electronic theory as used in examining the structure of organic molecules and the mechanism of their reactions Another gives an introduction to aromatic chemistry These special chapters form a sandwich between the earlier ones on the aliphatic compounds, beginning with the paraffins, and the succeeding ones on aromatic compounds Then follow chapters on oil, coal, the chemicals derived from them, and polymers They give very useful accounts of many modern developments on the industrial side of the subject A penultimate chapter on analysis is followed by a short, but very useful, one in which the more important types of organic synthetic reactions are conveniently grouped together Chapters on the homologous series give a clear summary of the general nature of the compounds Important individual members are given separate treatment which includes preparative details Towards the end of each chapter, additional preparative work and simple test-tube reactions are outlined which use up little material or time A selection of questions from papers of various examining boards and university scholarships concludes each chapter and a further hundred appear in an appendix Fifteen pages of a general index are followed by short indexes covering named reactions, important terms and inorganic reagents

H DUNNICLIFF

MICROANALYTICAL TECHNIQUES

Quantitative Chemical Micro-Analysis

By Prof C J Van Nieuwenburg and J W L Van Ligten Translated by C G Verver (Elsevier Monographs Chemistry Section) Pp viii+181. (Amsterdam and London Elsevier Publishing Company, 1963) 35s.

QUANTITATIVE Chemical Micro-Analysis is an English version of the original Dutch *Kwantitatieve Chemische Microanalyse*, which describes those microanalytical techniques which have been exhaustively studied and systematized at the Technical University, Delft The authors, Emeritus Prof Van Nieuwenburg and his successor, Dr Van Ligten, are both investigators of eminence in the microchemical field, and their views on the didactic and practical applications of this science will command much attention both in teaching institutions and in the industrial laboratories

They predict that "microanalysis will become the standard form of chemical analysis" and emphasize the saving in cost, the application to minute quantities of starting material and the general neatness and elegance of the method used The development of single-pan fully automatic balances is rightly regarded as a major advance in technique, and the normal practice of permitting objects to reach equilibrium with the vapour of the ambient atmosphere before weighing is strongly advocated, as is the expedient of removing electrostatic charges from the balance housing by means of ionizing radiation The present edition is pocket-sized and contains 181 pages Fifty-three pages of the book are devoted to very detailed descriptions of single gravimetric determinations of numerous elements and acid radicals at concentrations approximating to 1 mg per ml, for example, bismuth with triethylenediamino-cobaltic iodide, silicate as pyramidone silicomolybdate, etc Apparatus for micro-separations is fully described

Twenty-two pages deal with microgravimetric separations of mixtures containing two simple metallic elements, for example, lead and thallium, the following 38 pages being devoted to microvolumetric analysis

The Strohlein or Metrohm plunger-type burettes with 'Teflon' pistons and a capacity of 2 ml are recommended for N/50 titrants Gorbach burettes are described, but the presence of a meniscus causes after-flow The British 'Agla' syringe can be used both as a pipette and as a burette

Much attention is directed to ethylenediamine tetraacetic acid microtitrations, and there are numerous practical examples of direct replacement and of back titrations using 0 02 M solutions.

The volume ends with a most useful chapter on quantitative elementary organic analysis Carbon and hydrogen are determined by the method of Belcher and Godbert, the halogens by the ter Meulen-Sloof technique or alternatively by the Schoniger oxygen-flask Nitrogen is determined by ter Meulen hydrogenation using Ni-ThO_2 catalyst or by the modified Dumas method Didactic considerations have led Van Nieuwenburg and Van Ligten to exclude descriptions of well-known methods such as those of Unterzaucher for oxygen or Zimmermann for sulphur

A useful description is, however, given of molecular weight determination on a micro-scale utilizing the 'isothermal distillation' technique as suggested by Barger, developed by Wright and modified by Van Nieuwenburg and Van Ligten

This publication has a wholesome practical bias and will have an undoubted value and appeal to teachers of microanalysis in academic institutions It has also much to offer the practising analyst who may be called on to work with rather restricted quantities of a parent substance or who wishes to economize on his financial outlay

D T LEWIS

FOREIGN CHEMICALS IN FOODS

Residue Reviews

Residues of Pesticides and other Foreign Chemicals in Foods and Feeds Edited by Francis A. Gunther Vol 1 Pp iv+162 Vol 2 Pp iv+156 Vol 3 Pp iv+170 (Berlin Springer-Verlag, 1963) 22 D M each volume

THE incorporation, often inadvertently, of foreign substances in foodstuffs has caused increasing concern in recent years Attention has been directed especially to residues of chemicals which are needed to control pests, diseases and weeds in crops in the field, to combat parasites of animals used for food, or to protect foodstuffs in transit or storage Much work has been devoted to finding how the crop protection and related chemicals may be safely used A new and specialized field of residue analysis has emerged allowing the levels of contamination in harvested crops to be determined, and the behaviour and ultimate fate of the chemicals have been extensively investigated Some are lost from crops by weathering, some are degraded into harmless derivatives by the plant or animal, and others are eliminated during food processing Some chemicals, however, persist on crops and in soil, tend to accumulate in animal food chains, and may endanger public health in due course Associated with the chemical examinations are toxicological investigations to determine the significance of the residues that may be found Statutory and other measures adopted to protect the consumer include the institution of permissible limits of contamination, maximum recommended rates of use of potentially harmful chemicals, and the observance of adequate periods for weathering

The object of *Residue Reviews* is to bring together the many aspects of the problem of foreign chemicals in foodstuffs The use of substances to improve flavour, appearance, etc , and contamination incurred during manufacture, packaging, etc , are also considered to be suitable subjects for discussion Contributions are made by invitation, and an advisory board of specialists from many countries indicates the international scope of the publication

The three volumes that have so far appeared deal largely with problems arising from the use of chemicals for crop protection. General articles describe the nature of plant surfaces in relation to the use of spray chemicals, the absorption, translocation and metabolism of chemicals in plants, and the processes involved in deposition, degradation, persistence and effectiveness. A valuable series of papers on analytical methods show the advantages conferred on residue analysis by modern techniques of chromatography, polarography and spectrophotometry A few contributions discuss the levels of residues that are found in practice, one deals with the principles underlying the establishment of residue tolerances, and another examines the difficulties and interpretation of tests for carcinogenicity Each article gives summaries in English, French and German and useful references

Work on residues in foodstuffs is expanding so rapidly, and information is scattered in so many journals, that undoubtedly there is ample scope for a publication of this kind To be fully effective, its professed aim of international coverage should be attained, at present emphasis rests on work and reports from the United States, a position that no doubt will change when the series becomes established Many of the contributions give valuable information, but some scarcely reach the standard that may reasonably be expected A considerable amount of tidying-up is needed before the presentation will satisfy critical appraisal· proprietary and coined names of chemicals are used indiscriminately, inconsistencies occur in chemical names, and the subject index is quite inadequate. This last deficiency detracts much from the merits of an otherwise commendable, if expensive, publication

J T MARTIN

ANALYSING FOOD CONTAMINANTS AT LENGTH

Analytical Methods for Pesticides, Plant Growth Regulators and Food Additives

Edited by Gunter Zweig Vol 1. Principles, Methods, and General Applications Pp xiv+637 (New York Academic Press, Inc ; London Academic Press, Inc (London), Ltd , 1963) 171*s* 6*d*

PARKINSON'S Law states that work will always expand to fill the time available for its execution The same principle surely applies to publishers with an infinite supply of paper, editors with an inexhaustible number of contributors and libraries with a seemingly unlimited provision of dollars The present book is priced at £8 11*s* 6*d* Its purpose is to serve only as an introductory review of the principles and general applications of the analytical methods which are to be described in Volumes 2, 3, 4 and 5 that have yet to be published The fortunate possessor of the entire compilation, who will, if he reads all the 3,185 pages which it will doubtless comprise, know all there is to know about the analysis of crops and food for traces of pesticides, plant growth regulators and food additives, will therefore have paid £42 17*s* 6*d* for the privilege

A number of the authors of individual chapters discuss what they call the "clean-up procedures" by which they concentrate the trace residues in which they are interested and free them from the bulk of the sample If an analogous process could have been applied to the book itself, everyone would have been the gainer because there is much in it of value W Thornburg, for example, contributes an admirable, short, clear and practical chapter on the various methods by which trace contaminants of different classes can be separated from the materials with which an analyst may be confronted The chapter by A Bevenue on the application of gas chromatography to the analysis of traces of fumigants, insecticides, herbicides and a list of miscellaneous compounds including phosphorus halides, chlorobenzenes, insect repellents, fungicides, mould inhibitors and antioxidants is a model of how theoretical principles and practical details can be succinctly combined The table of relative retention times on differently packed columns of a long list of pesticides will alone put many analysts in his debt P McKinley's article on paper chromatography is equally satisfactory, the combination of paper chromatography with fly bioassay and cholinesterase-acetylcholine reactions may be novel to workers in other fields There is an interesting, sensible chapter by R Moffitt on residue analysis in the dairy industry, and a useful and informative one by Z F Krzeminski and W A Landmann on methods for pesticide analysis in meat products which may surprise more old-fashioned workers by the number of antibiotics, hormones, arsenical compounds, tranquillizers, antioxidants and pesticides that there may be in a carcass in this modern age

But the speed at which science is advancing is brought home most forcibly by two quite different contributions One is by R Fisher it describes methods for assaying the potency of "microbial pesticides" A "microbial pesticide" is a living micro-organism designed to infect one or other of the insects which constitutes an agricultural nuisance There are at the present time four of these preparations on the market in the United States Three contain specific bacteria—*B thuringiensis*, *B popillae* or *B lentimorbus*—and one a virus as active ingredients Here, indeed, is need for a new sort of analysis The second article by R A Schmitt gives a matter-of-fact account of the elegant analytical procedure by which very small trace concentrations of a diverse variety of substances can be determined simply, quickly and often without the need for preliminary treatment of the substance under examination by the use of neutron activation analysis, a technique in which specific radioactivity is induced in the sample by exposing it to neutrons from a nuclear reactor In view of this evidence of the pace at which scientific understanding and its applications are progressing, is it really ungenerous to doubt whether analytical methods will stand still long enough to make it worth while saving up for Volume 5 of this work? MAGNUS PYKE

FOOD PLANT HYGIENE

Food Plant Sanitation

By Milton E Parker and John H Litchfield Pp v+401 (New York Reinhold Publishing Corporation; London. Chapman and Hall, Ltd , 1962) 96*s* net

IT is somewhat surprising, considering the importance of food plant sanitation ('food plant hygiene' in Britain) to food manufacturers, public health officers and others, that so few books have been published on this subject Many that have been published have not been revised to bring them up to date, this despite many recent developments *Food Plant Sanitation* is, therefore, welcome, it is a good book and, for its size, very comprehensive Unfortunately this is a subject which is hedged around with many legal requirements, and this book is written with the U S Food, Drug, and Cosmetic Act particularly in mind Also, although there are more than 500 references, these are predominantly of American origin The user of the book in the U K will have to have beside him the corresponding British regulations and the many excellent publications of H M.S O relating to this subject

To some extent this concentration on American practice will be of value to readers in Britain They may gather how far, if at all, Britain is behind the United States in food hygiene and they should get some idea of the precautions that must be taken if foodstuffs are to be exported to the United States

The first chapter deals with the role of sanitary practice in quality control and the second with sanitary aspects of buildings and equipment The third, fourth and fifth chapters consider insect and rodent pest control, and then follows a chapter on the effective control of micro-organisms This includes details of the new organic chlorine products which are now gradually coming on to the market in the United Kingdom after being in use in the United States for some time Chapter 7 deals with sanitary aspects of water supplies and Chapter 8 with waste disposal and utilization Some of the methods described here are as yet unfamiliar in Britain, such as the anaerobic digestion system for meat packing-plant wastes Effective detergency and cleaning practice is considered in Chapter 9 This is a thoroughly up-to-date account, and modern detergents and the latest types of clean-in-place methods are mentioned Chapter 10 is headed "Establishing Sanitary Practices" and considers the duties of the 'sanitarian' in the food industry This is a 'species' of which there is no exact counterpart in Britain; perhaps there ought to be The following chapter on "Maintaining Sanitary Practices" deals with such things as employee training in sanitary practices. The last and twelfth chapter is a useful one on the sanitary aspects of packaging material and methods An appendix gives excerpts from the U S Food, Drug and Cosmetic Act and amendments

This book should prove of considerable value to managers, chemists and microbiologists in the food industry, and also to public health officers and consultants concerned with food hygiene H. D G ROPER

ADVANCES IN ENZYMOLOGY

Advances in Enzymology and Related Subjects of Biochemistry

Vol 24 Edited by F F Nord. Pp v+572 (New York and London Interscience Publishers, a Division of John Wiley and Sons, 1962) 120*s*

THE synthesis of enzymes in the living cell and the determination of their structure form part of the much wider problem of protein biosynthesis in general, with all its subtle intricacies of amino-acid activation, energy expenditure and genetic control by nucleic acids Some of the recent enzyme research appears to have been undertaken not so much to provide an answer to the question why a given enzyme specifically acts on one but not another substrate, but with the purpose of unravelling the mechanism of protein biosynthesis, whereby determinations of enzymatic activity serve as a convenient indicator of protein function

In Volume 24 of *Advances in Enzymology and Related Subjects of Biochemistry*, Chantrenne deals at length and in depth with the problem of how biochemical tools receive orders from the genes and how they put them into operation He is well qualified by his own researches to write on that subject, and acts at the same time as an able exponent of the Brussels School, which has significantly contributed to the present-day knowledge of the relationship linking nucleic acid with protein biosynthesis

The manner in which the gene-controlled information determines biosynthetic pathways and the structure of cellular proteins is a repetitive theme in several chapters of the volume The practical approach to the problem of cellular localization of enzymes and their synthesis has greatly benefited from the techniques of centrifugal fractionation developed in another Belgian laboratory, namely, that of de Duve at Louvain It is, therefore, most welcome to have an authoritative, as well as informative, chapter by de Duve, Wattiaux and Baudhuin, on the distribution of enzymes between the sub-cellular fractions in animal tissues Far from being a mere catalogue of results, this chapter can be used as a guide in the application of centrifugal fractionation to the investigation of a variety of biochemical processes.

Among the few enzymes of which the amino-acid sequence has been well established is the ribonuclease, which at present receives a great deal of attention from protein chemists as well as enzymologists The structure and function of ribonuclease form the main topic in the chapter by Scheraga and Rupley, who provide a clear and concise survey of the subject But ribonuclease enters into discussion also in several other chapters, notably that concerned with mechanisms of enzyme catalysis by Westheimer, and the one by Sri Ram, Bier and Maurer, who deal with chemical modifications of proteins and their impact on enzymology, immunochemistry and related subjects. Ribonuclease again figures prominently in the chapter on peptide structures by Šorm, whose analytical results on proteins form the basis of his evolutionary concept whereby the chemical structure of proteins is seen as a reflexion of the evolution of life on Earth, a record, as it were, of the laws of phylogeny and ontogeny of the distant past

Of the three remaining chapters, that by Augenstine offers a detailed and very useful account of the six existing models of enzyme radiosensitivity, in the chapter on sperm metabolism, Salisbury and Lodge expound their views and experiments on the subject of the relationship between sperm survival, motility and metabolism, and the response of spermatozoa to a variety of extraneous agents, lastly, there is a review on molecular properties and transformations of glycogen phosphorylase in animal tissues, by Edwin Krebs and Edmond Fischer, dealing with the first step of glycogenolysis, a process significantly more complex than originally visualized, as it now appears to involve no less than four different enzymes, three nucleotides, a vitamin, and several hormones and metal ions T Mann

PHYSICS IN BIOLOGY AND MEDICINE

Advances in Biological and Medical Physics

Vol VIII Edited by Cornelius A Tobias and John H Lawrence Pp ix+457 (New York and London· Academic Press, 1962) 107*s* 6*d*.

THREE of the eight topics presented in the latest volume in this series are concerned with techniques for the measurement of trace elements, X-ray spectroscopy by J W Gofman, neutron activation analysis by Kwan Hsu and γ-ray spectroscopy by L D Marinelli, C E Miller, H A May and J E Rose, the latter restricted to the external measurement of radioactive elements located within the human body These chapters provide useful descriptions of the physical techniques involved and of the relative sensitivity for different elements Various medical and biological applications of these techniques are described, but with little indication as to their usefulness in comparison with other techniques However, this may be due to the fact that they have not as yet been applied very widely

A chapter by Tor Brustad gives an excellent account of the experimental set-up of the heavy ion linear accelerator (*Hilac*) at the University of California Applications in the field of radiobiology are presented which illustrate well the usefulness of this machine, and also the complexity of interpretation of the experimental results

A lengthy chapter on the interrelations between the hypothalamus and the thyroid is provided by P Blanquet in collaboration with J Faure The detailed descriptions of experimental observations by many workers make it difficult, for those new to the subject, to ascertain what the authors consider to be the most likely mechanisms operating between these two organs However, those working in this field should find the chapter most useful

With the all-embracing title "The Origin of Life on Earth and Elsewhere", Melvin Calvin describes the properties that are required of molecules so that they can give rise to primitive forms of life He describes how simple polyamides and nucleic acids may have interacted and evolved to the great complexity of the biochemical processes that are found in even the simplest organisms to-day

"The Physics of Space Radiation", by Roger Wallace, deals with the various sources of ionizing irradiation found in space and concludes that only that resulting from sporadic solar flares is of real danger in future distant space flights It is suggested that a few minutes' warning of these flares can be obtained so that spacemen may shelter in some well-shielded part of the space vehicle

The final chapter, by Niels Arly and Reidar Eker, is entitled "Mechanisms of Carcinogenesis" After an interesting presentation of the complexity of the carcinogenic process, various mathematical models are considered and the need for a stochastic model is argued Such a model that has been constructed by the authors, is shown to be able to fit satisfactorily a number of results relating different experimental parameters The absence of any information concerning the biological mechanisms involved leaves one with the impression, however, that no real advance has been made in this field N M Blackett

NUCLEOPHILIC ALIPHATIC SUBSTITUTION : MECHANISM AND KINETICS

Nucleophilic Substitution at a Saturated Carbon Atom

By Dr C. A Bunton (Reaction Mechanisms in Organic Chemistry, Vol 1) Pp ix+172 (Amsterdam, London, New York Elsevier Publishing Company, 1963) 40*s*

THIS is the first volume in a series edited by (the late) Prof E D Hughes, and sets an excellent standard for the series as a whole The monograph also occupies a proper position in the series, as the general principles, which are adumbrated in Chapter 1, are useful in other areas of physical organic chemistry, the subjects of following volumes While ideally it might have been better to treat nucleophilic substitution as a saturated carbon atom in the same volume as elimination reactions, there are good practical reasons for the procedure adopted of limiting this volume to substitution only

In places this work leans heavily (but rightly so) on parts of Sir Christopher Ingold's magistral volume, now some ten years old, *Structure and Mechanism in Organic Chemistry* However, in the controversial parts of the subject the author, himself a distinguished member of the University College, London, school, has shown an admirably balanced and fair attitude, especially to the work of American protagonists in the controversies The book is also noteworthy for numerous critical and illuminating footnotes (unfortunately printed in very small type) for many well-chosen references, situated at the end of each chapter, but easily found, because their location is given on every alternate page of the chapter in question

After an opening chapter in which mechanistic and kinetic principles are discussed, with special reference to 'duality of mechanism' (the definitions of the S_N1 and S_N2 mechanisms might have been rather more rigidly set out), the author proceeds to the two most substantial parts of his book—a thorough survey of structural effects on the rate of substitution, and a penetrating account of the stereochemistry of the substitution process in relation to mechanism, which is still one of the most satisfying areas of rationalization in physical organic chemistry

The next two chapters are devoted to solvent and salt effects these are matters of considerable subtlety where the subject is still growing, and raise issues of great theoretical interest, and in the first case of great practical importance There are a brief final chapter on electrophilic catalysis and an addendum dealing with important matters which have arisen since 1961, the date to which the literature has been covered in the main text

All students of physical organic chemistry will wish to study carefully the volume as a whole, and the greater part of it will be valuable to organic chemists generally, especially to third-year honours and first-year Ph D students

N B CHAPMAN

CELLULAR ORGANIZATION

Funktionelle und Morphologische Organisation der Zelle

Wissenschaftliche Konferenz der Gesellschaft Deutscher Naturforscher und Arzte in Rottach-Egern 1962 (9 Beitrage in Deutscher und 6 Beitrage in Englischer Sprache) Pp iv+253 (Berlin, Gottingen and Heidelberg: Springer-Verlag, 1963) 36 D M.

FOR a long time the great issues of cellular organization have been argued in terms of the nucleus The problem has been that of the relations of its physical structure, its chemical activity and its genetic permanence or continuity Now, with the help of electron-microscopy, autoradiography and other techniques, the problem has, as we may say, boiled over into the rest of the cell A wide range of results of this boiling over is displayed in the present symposium A general statement of its purpose and its problems is, however, lacking

It was the continuity and activity carried together by the nucleus which first struck the imagination of cytologists, German cytologists, in the nineteenth century. Clearly any structure in the cell which can achieve this difficult combination deserves to be given the status of an organella Any body which can fulfil its short-term duties within the cell while meeting the long-term needs of propagation and distribution to different cells will thus qualify for this status Presumably, therefore, any of the cell structures in which DNA is now beginning to be recognized will also qualify How far will this property extend ?

The answer to this question has usually been derived in the past from the evidence of experiment, but experiment of the most varied kinds with the most varied organisms The breeding of plants has shown us the self-propagation of the plastid The embryology of animals has demonstrated the same property in the centrosome The development of Protista has revealed the genetical continuity of their versatile fibre-forming organellæ The evidence of immunology has left little doubt of a similar propagation in the higher animals Here, and in the plasmagenes to be inferred from the heredity and development of the higher plants and animals, we do not know what particles or structures provide the basis of continuity But in this symposium both the electron microscope and chemical analysis introduce us to a number of possible candidates for these duties

No such central idea is, however, advanced to give unity to the present discussion Nor is there indeed any central idea in biochemistry which might offer itself for such a purpose The most nearly central problem is that which comes from the work of Mechelke and Beermann with the polytene chromosomes of flies The connexion between heredity and development, and between DNA and RNA, revealed by these studies of development and differentiation, gives us a glimpse of what has long been suspected the hierarchy of structures and functions which lie between the genetic code and its expression It is a hierarchy which will require us more and more to study the cell as a system and to use all the available degrees of magnification in seeing how it has been built and organized. In order to succeed in this task we shall have to exploit our resources in more variety than is done in this symposium Older and newer techniques will have to be more fully combined Plants, omitted from this discussion, will not have to be left out For it is already easy to see that, after the nucleus, their plastids will play the most important part in knitting our ideas together

C D DARLINGTON

THE SENSES OF INSECTS

The Physiology of Insect Senses

By Prof V. G Dethier (Methuen's Monographs on Biological Subjects) Pp ix+266 (London Methuen and Co , Ltd , New York John Wiley and Sons, Inc , 1963) 42*s* net

THIRTY years have elapsed since Eltringham's monograph on *The Senses of Insects* was published in this series At that time, the greater part of the modern work on insect sense organs had been done in Germany This work received little reference in Eltringham's book, which presented the knowledge and ideas of an earlier epoch J. D Carthy dealt with the subject well in his *Introduction to the Behaviour of Invertebrates* some five years ago, but the new monograph by Prof V G Dethier, although it covers again much of the same ground, is very welcome, for it is written by an author who has been personally involved in some of the most significant advances in our understanding of the chemical senses of insects

The author deals at some length with those subjects which are most controversial at the present time the nature of the action of chemostimulants at the receptive site, and the basis of their specificity, the interpretation of the electroretinogram, the varying spectral sensitivity in different insects, and the chemical nature of the photoreceptive substances, the mechanism in the insect eye which enables it to perceive the plane of polarized light, the physiological basis of the great differences which exist between different tactile hairs, depending on the purpose for which such receptors are used, that is, their diverse properties with respect to adaptation, and in the effect of direction of movement on the nervous discharges that result In short, the emphasis throughout is on how insect sense organs work

Advances in the past ten years, supported by electronic methods of neurophysiology and by structural investigations with the electron microscope, have been spectacular From the studies of Slifer, in particular, we know that the thin cuticle which covers the chemoreceptive sensilla is perforated like a sieve and multiple fine dendrites in these perforations have their endings freely exposed to the atmosphere We know, particularly from the work of Dethier and his school, that a single chemoreceptive hair on the tongue of the blowfly is receptive only at the extreme tip, the fly responds positively to stimulation of the hair by sugar, and by water, negatively to electrolytes, and to the mechanical displacement of the hair Each of these perceptions is mediated by a separate dendrite and sense cell From the work of Roeder and Treat we know that although the abdominal ears of the moth have only two neurones apiece, they can recognize both the character and the direction of the cries of a hunting bat

Work done in all countries is well covered and a select list of about 700 titles is included The extensive German work is well reviewed, including that dealing with insect vision Our present lack of understanding in many parts of this subject is reflected in the obscurity of some of the

German writing about it This obscurity comes across in the English version One of the difficulties is how to reconcile the separate innervation of the seven or eight elements that compose the retinula of the ommatidium, with the mosaic theory of vision by the compound eye The recent contributions by Burtt and Catton and by N Yagi were not published in time to receive critical consideration in Dethier's account

This monograph can be strongly recommended, but it is a technical monograph which makes few concessions to the possible limitations of the reader

V B WIGGLESWORTH

PHOTOGRAPHIC DIORAMA OF WILDLIFE

The Wonders of Wildlife in Europe

By Franz A Roedelberger and Vera I Groschoff Pp 232 (280 pictures) (London Constable and Co, Ltd, New York Viking Press, Inc, Toronto· Longmans Green, 1963) 42*s*

THE rise and rapid advance of colour photography in recent years have placed in the hands of the book illustrator a wonderful medium for the illustration of ornithological works

The Wonders of Wildlife in Europe is a fine example of what can be done in this respect It is a picture book, a collection of 280 remarkable photographs, the striking illustrations being accompanied by descriptive paragraphs telling the reader some facts concerning the subject, or rather subjects, shown in the pictures These cover a wide field, from marine life and insects to reptiles, mammals and birds The leading natural history photographers of Europe have contributed to the gallery

By their grace and beauty, birds afford the artist wonderful subjects, and here are shown some of the exquisite results that can be achieved by those using what we may term the 'new medium'

Comparisons are ever invidious, yet they must inevitably arise in a case such as this when we think of the great illustrated bird books of the past, the work of artists who never dreamed of a time when the camera would come into being and take over much of their work Personally I do not think comparison possible The beauty of a plate from Gould's *Humming Birds* cannot be compared with the study of an elephant hawk moth shortly after emerging from the pupa, on p 162 of *The Wonders of Wildlife in Europe*, or the portrait of a little Egyptian vulture on p 41 Each in its way is a thing of beauty, and if the ways are different ways the contrast enhances them

In this volume the colour pictures are, of course, the most eye-catching and impressive of the illustrations, but there are also a large number of monochrome reproductions, including some remarkable snapshots such as that of two young foxes having a dispute and fighting heartily Seemingly the trouble arose over a white hen Another fine shot shows a female white-toothed shrew, *Crocidura leucodon*, followed by her family The first young one is grasping the mother by the fur of her rump, while the rest of the litter are in line astern, holding on to the hindquarters of the one ahead, there are six in all

For the depiction of sheer joy and delight in life a fox-cub springing high in the air (p 196) is hard to beat, it is such a fine photograph and the young animal is in such a joyous pose Another remarkable photograph is of a herd of wild reindeer in extended formation, described as a view over Hardanger Vidda, Norway

There is a foreword by Peter Scott stressing the need to protect wild creatures and laying stress on the problems of the conservation of animal life in general, now and in the future

FRANCES PITT

PRODUCTIVE CYCLES IN THE OCEAN

Plankton and Productivity in the Oceans

By Prof John E G Raymont (International Series of Monographs on Pure and Applied Biology Division Zoology, Vol 18) Pp viii+660 (London and New York Pergamon Press, 1963) 110*s* net

THE first four chapters in this book on oceanic production give a brief account of physical oceanography as it affects life in the sea The distributions of temperature, salinity, oxygen and carbon dioxide are described Pictures of the oceanic current systems are reproduced from Sewell[1] This is part of an attempt to "approach the study of oceanography through biological science". Much of the physics and chemistry relevant to the study of productive cycles is to be found in later chapters

The subject of production is introduced with a chapter on the phytoplankton. The structure of diatoms, dinoflagellates and μ-flagellates is well described The illustrations are clear and well reproduced The decrease in size of diatoms, division rates, formation of auxospores, heterotrophy and flotation are physiological subjects brought into the discussion, which are of particular interest to production biologists Prof Raymont defines nanoplankton as plant cells "not normally retained by the finest silk nets" and they belong to "a variety of plant groups, Chrysophyceae, Chlorophyceae and Cryptophyceae", Yentsch and Ryther[2] are quoted as showing that "the major part (of nanoplankton) is made up of small diatoms rather than microflagellates" Prof Raymont says that the quantitative estimation of nanoplankton is extremely difficult It is quite true that μ-flagellates cannot be counted, but small diatoms and dinoflagellates can be counted quite well with Utermohl's sedimentation technique[3], which is not mentioned

Algal production is described in five chapters An introductory one deals with photosynthesis, compensation depth and compensation point, the inhibition of photosynthesis at high-light intensities near the surface and the adaptation of photosynthesis (measured as mg carbon/mg chlorophyll/h) to different conditions The next four chapters treat of nutrients, light, micronutrients and grazing respectively Since the time of Lohmann[4], who counted all the plankton and who made a simple model of plankton predation, it has been clear that any productive-cycle is a complex sequence involving all these factors all the time The division into chapters treating the factors separately is a little artificial Indeed, one might say that the study of production is not fully described until the chapter on grazing, where the models of productive cycles are dealt with

In the chapter on nutrients, the seasonal changes in phosphorus, nitrogen and silicon and their distributions in the oceans, both vertically and horizontally, are well described It is said that silica is rapidly regenerated, I believe this is so, but the evidence is not given, nor is any authority quoted In the subsequent chapter (on light) a diagram of the nutrient-cycle is given, showing that the decline in nitrogen and phosphorus starts in late April well after the peak of the algal outburst at the end of March This is what happens at Plymouth, comparing Fig 7 29 showing seasonal nutrient distributions with Fig 8 1 giving the seasonal algal distribution In contrast, Fig 7 2 (showing seasonal distributions of phosphorus, nitrogen and chlorophyll in Long Island Sound, from Riley and Conover[5]) demonstrates that the chlorophyll peak occurred exactly when the very low values of nitrate were reached It is this sort of contrast that suggests that the effect of nutrient lack on algal production is not a simple one In discussing models, Prof Raymont points to the need for good physiological estimates Here is one badly needed—the effect of various nutrients on algal division rates A little has been done, but not enough

Seasonal cycles in algal production are described in the next chapter on light and primary production A good account is given of the initiation of productive cycles and of the penetration of light into the sea Another chapter describes the part, if any, played by micronutrients in productive cycles Here again are needed experiments establishing the effect of nutrient concentration on algal division rate

The effect of grazing on algal production is well described, the work of Harvey, Cooper, Lebour and Russell[6] and the work of Fleming[7] being given in some detail. This leads naturally to an account of the model techniques used by Riley and others to describe the course of algal production as a whole Here Prof Raymont makes a good summary of the part played by the various factors, nutrients, light, vertical turbulence and grazing He is perhaps a little chary of setting out any model in its mathematical terms, preferring to state it in words

A systematic account is given of the zooplankton The pictures showing the structure of these animals have been well reproduced In a chapter on geographical distribution, the work on plankton indicators is reviewed lightly, mainly to show where different animals and communities live, rather than to show whether ocean currents can be charted by indicators The seasonal cycles of plankton animals are described briefly giving generation times From this clear review, it appears very strikingly that from all the work on seasonal cycles of zooplankton, there are very few good estimates of reproductive rate, growth rate or mortality rate

A full description of the vertical distribution of plankton animals is given, including their diurnal migrations. It should be emphasized that bathypelagic decapods, euphausiids, sagittæ and fish larvæ dodge slowly hauled plankton nets so some vertical migrations quoted are perhaps not migrations at all In describing the mechanisms that plankton animals might use, Prof Raymont discusses geotaxes and phototaxes in rather loose terms Phototaxis should be defined in terms of the two-light experiment[8], it is difficult to see how the conditions of this experiment reproduce those found in the sea, particularly at dusk and dawn when the important parts of migration occur. Harris's work on the various mechanisms of behaviour that plankton animals can use is not described[9,10], this is an omission

Prof Raymont's own work is concerned with the feeding and respiration of zooplankton His account of this subject is extensive, ranging over the types of food, the quantities eaten and how they are linked to the respiratory rate He does not define the term "filtering rate", which is a volume swept clear of food particles per unit time By an experimental convention, the value is derived from a total mortality rate of algal cells per unit time If the algae are reproducing, the true grazing mortality rate can be higher than the apparent total mortality rate. Because this second step is sometimes not taken, many experimental values of "volume swept clear" are too low Again, Marshall and Orr's method[11] of using phosphorus-32 gives the quantity of food assimilated, but it is not derived from the grazing mortality of the algae A large number of measurements are discussed as if they all meant the same thing Each of the three methods (from total mortality rate of the algae from grazing mortality rate of the algae, and from quantity of food assimilated) is valid in its own right, but should be distinguished in the discussion Prof Raymont goes on to discuss how the zooplankton survive and how the various model techniques in use so far describe the acts of grazing and feeding He concludes that "better results can be achieved only with a greater accumulation of precise knowledge of the physiology of zooplankton" It is astonishing how slowly this precise knowledge is accumulating

The book is intended for workers beginning investigation in the marine field It will find a wider circulation than that There are good and complete accounts of the various parts of the productive cycle in the ocean The history of each development is well described, for example, the progressive search for a nutrient which limits production or for a model which fits the data

The literature cited is almost all in English, excluding much good work in Russian and German, for example, Beklemishev[12] has shown that *Calanus finmarchicus* Gunner is armed with silica teeth D CUSHING

MATERIALS AND METHODS FOR MASTERING MENDELISM

Teaching Genetics in School and University
Edited by Prof C D Darlington and A D Bradshaw
Pp x+117+4 plates (Edinburgh and London Oliver and Boyd, Ltd., 1963) 21*s*

GENETICS is not easy to teach, since to understand the subject-matter the student requires a knowledge of certain aspects of several disciplines including biology, chemistry and mathematics What makes matters worse is that there seems to be an alarming negative correlation between biology and a knowledge of mathematics, anyhow in university students

Because of difficulties in teaching genetics, a number of people with practical experience in it participated in a symposium in order to try to assist themselves and others to improve their methods The meeting, at which I was present, aroused considerable interest in the audience and provided some very helpful suggestions *Teaching Genetics in School and University* is an account of the contributions of each of the participants, together with additional notes on genetics in schools, on certain demonstrations and on sources of material for teaching

The opening contribution by Prof J M Thoday on the organization of genetics teaching in universities gives a brief account of the contribution genetics can make to teaching in those other disciplines between which it forms a bridge In view of this connecting quality, Prof Thoday suggests that a department of genetics should provide a service to other departments, anyhow at an elementary level of teaching, and that special departments covering particular aspects of genetics such as biochemical genetics or human genetics should be viewed with disfavour Prof Thoday's article is stimulating and should be read by all interested in the teaching of the 'life sciences'.

The remainder of the book is devoted to special topics, with particular emphasis on methods of giving practical instruction in genetics The teaching of microbial genetics using bacteria, bacteriophages, fungi and yeast is discussed at considerable length by workers distinguished in this field of genetics There are also contributions on biometrical genetics, developmental genetics and cytogenetics by equally distinguished workers Particular mention must also be made of the article by Prof C D Darlington on the organization of a genetic garden, a most useful adjunct to any department of genetics At the end of the book there is also a section on "Genetics in Schools", brief notes on organisms, materials and experiments that can be used for particularly illuminating practical work and demonstrations, as well as a most useful list of sources of material for teaching genetics.

The coverage of the various aspects of genetics is extremely uneven, and the contents of the various contributions show marked evidence of being conceived quite independently of one another. Consequently, the editors have seen fit simply to group the contributions by broad subject The methods of teaching microbial genetics and cytology are well covered Evolutionary genetics is less-adequately dealt with, although there are some excellent suggestions by Dr. A D Bradshaw and J G Pusey for showing the results of natural selection with respect to the production of hydrogen cyanide in white clover and the evolution of heavy-metal tolerance in several plants Quantitative genetics is perhaps the most difficult of all the sub-divisions of genetics to teach to undergraduates, particularly without practical work Unfortunately the present symposium does little to remedy the difficulty Dr J L Jinks describes an excellent course in biometrical genetics for those few with the ability, but, as he himself admits, many of the undergraduates fall by the wayside because of a lack of the necessary mathematical knowledge Prof Thoday describes a very useful practical exercise in quantitative genetics, but it would have been helpful if several other similar exercises could have been included in the book

The reader hoping to find a course of genetics designed for him will be disappointed by this book, as indeed he must be There is little help to be found by those who hope for a list of topics suitable for a lecture course, other than that given by Dr Jinks and some suggestions for teaching cytology by Dr H Rees The ideas for practical work are not extensive enough to be useful for a complete practical course The reference to genetics in schools in the title seems to have been added as an after-thought to attract a wider public A few of the suggestions, particularly those by D S Falconer on the use of mice, those specifically for schools by Dr Bradshaw, some of the exercises in cytology described by K L Lewis and Dr B John, as well as those by A P Wylie and some of the brief notes, will be of use to a number of school teachers The majority of methods and suggestions require the student (and the teacher) to have an extensive background knowledge and will only be suitable for specialized scholarship work in the sixth form However, the book is going to be of very great use to all those university teachers of genetics who want some suggestions for practical work in fields in which they have not themselves worked, and for this purpose the book can be highly recommended

P. M SHEPPARD

TECHNICAL AND BUSINESS ASPECTS OF FARMING

Farming

General Editor Prof A N Duckham Vol 1 Pp xxiii + 543 + 16 plates Edited by C A Jewell Vol 2 Pp xv + 640 + 16 plates Edited by S Fox Vol 3. Pp xv + 585 + 15 plates Edited by J A C Gibb Vol 4 Pp xv + 501 + 14 plates Edited by Dr J Pearce (London, New York and Melbourne The Caxton Publishing Co, Ltd, 1963) 345s per set of four volumes

THIS book of four volumes on British farming appears at a time when doubts are being raised as to whether the science and up-to-date practices of farming can be treated adequately in one work, its contents give an indication of some of the difficulties Preparation of the four volumes must have taken a number of years, even though shared by the general editor, his four joint editors and eighty-one contributors, and that same period has seen a number of changes in farming, when proved and established practices have been challenged by alternatives largely directed to the saving of manpower and the reduction of costs The task, then, of the many contributors was far from easy in that they were writing of modern and changing techniques and with an eye to likely developments A little of what was written, say, three years ago is out of date, but the authors are to be congratulated on the forward-looking views they have expressed, and in the overall presentation of an interesting review of the practice and science of farming

Farming is written as a practical book for practical men and certainly fulfils that objective for those with an elementary knowledge of the natural sciences It is a useful supplement in helping the farmer to understand the whys and wherefores of what he is doing and how to plan ahead It is also of direct interest to those in industries associated with agriculture

Volume 1 (plants, soils, crops and grass) opens with an interesting account of soil formation and the structure of plants, and then leads on to describe the various ways of improving soils and controlling weeds The tillage crops are each dealt with in turn under three broad sections of field cultivations, harvesting and general information There seems no serious objection to this arrangement if the book is being used for reference For anyone investigating a particular crop, there is merit in bringing together all the information on that crop This arrangement would also help to eliminate the repetition that one detects here and there

The final section of this volume deals with the grass crop It gives an interesting account of types of natural grassland, grass breeding and the value of improved strains Modern methods of managing grass are described, including the newer techniques, which recently have directed attention to the high value of this crop in British agriculture

Volume 2 (livestock), under the title "The Framework of Production", discusses inheritance, the evolution of breeds, the control of growth and food requirements The information is well laid out and is a useful introduction to the more practical aspects of animal management outlined in the later sections of the volume Beef and sheep farming, two very important farming enterprises, would seem to merit rather more attention than the respective 20 and 19 pages allotted to them Milk production in its many aspects, on the other hand, is treated generously with 100 pages The concluding section, "Starting and Maintaining an Animal Enterprise", contains many useful hints on small but important points of management that at times can easily be overlooked

Volume 3 (buildings, roads and machinery) breaks rather new ground in reviewing modern ideas as to the construction of farm buildings The emphasis is placed rather on new buildings, newer materials and the lay-out of farm-steadings, though structural repairs and the maintenance of old buildings also receive attention

The choice of farm power and field machinery and their operation are discussed in relation to the many jobs on the farm Advice is given on their efficiency under varying conditions and how far their use results in the saving of manpower The section forms a good introduction to the financial aspects of farm power and machinery examined in Volume 4

Volume 4 (management and a general index), as a study of farm management, could stand as a book by itself An interesting description of British farming is followed by a study of management under such headings as "Getting Started in Farming", "Farm Capital", "Farm Labour", "Management for Profit", and "Management Controls and Farm Planning". Many examples are given to show how a combination of technical knowledge and managerial ability is necessary for successful farming. The sections on management controls and farm planning in particular should be of great value to the practising farmer, large or small, in the conduct of his business.

The index to the four volumes runs to 126 pages (a double column of references on each page) On test, I found a minimum of trouble in turning up any particular reference This is a valuable feature, for at the price of 345s. the book may be in use as a reference in libraries as often as it is taken down from private book-shelves for reading and for study. It is a text-book as well as a reference book, written in good style and easy to read

It is not possible to cater for the specialist farmer or grower, even in a work of this size For example, only one chapter is set aside for fruit and vegetable growing, but readers will find a number of references to other publications in which fuller information may be obtained and useful notes as to how to use the book

There are 1,350 illustrations in all. The plates in particular are excellent in quality The many diagrams are clear and helpful, but a number of the smaller reproduced photographs are less well chosen, are indistinct and might have been omitted J A McMILLAN

DAIRY BACTERIOLOGY

Bacteriology for Dairy Students

By Dr Alan Seaman Pp vii+202 (London Cleaver-Hume Press, Ltd, 1963) 25s

COMPARED with their counterparts in North America, students of agriculture and dairying in Britain are poorly served with suitable text-books in the important subject of microbiology The publication of Dr Seaman's small text-book is, therefore, a welcome addition Dr Seaman is a younger recruit to the ranks of lecturers in microbiology, and it would be easy, and discouraging, to be over-critical of this first edition The subject which he has attempted to cover in 194 pages is large and obviously many aspects could receive only brief mention There is, however, a lack of balance in the treatment given in different chapters

In the opening chapters the author discusses the morphology, isolation and nutrition of micro-organisms It is unfortunate that the writer has chosen to illustrate various aspects of microbial morphology by somewhat crude drawings There are available to-day numerous excellent electron photomicrographs (for which, presumably, permission to reproduce could have been obtained), illustrating such features as the bacterial cell-wall, cytoplasmic membrane, spores, flagella, etc Use of such photomicrographs would have considerably enhanced this section

In the chapter on bacterial nutrition the author has made a commendable attempt to simplify a complex subject, but he has been unable to avoid using a terminology which may be beyond the grasp of the reader for whom the book is designed

Before proceeding to a discussion of the microbiology of milk and milk products, Dr Seaman has included four chapters on bacterial destruction, immunology, identification and variation, systematics and a chapter on historical development The chapters on bacterial destruction and systematic bacteriology are good, but immunology should have received rather fuller treatment than six paragraphs, in view of its importance in disease control in the dairy herd and in bacterial classification While the chapter on historical development reflects Dr Seaman's wide reading on his subject, it is doubtful if, in a short elementary text-book of this type, so much space should have been devoted to this aspect

It is regrettable that the development of the advisory services in England and Wales since the Second World War has divorced the teaching departments of colleges and universities, from intimate contact with problems of the agricultural and dairy industries As a result the chapters on the microbiology of milk and milk products give an unfortunate impression of a theoretical or academic approach to the subject and little attempt has been made to emphasize the more important aspects The work concludes with a short chapter on the microbiology of water and sewage

The book is written in a simple direct style, but occasionally the language is somewhat ambiguous. Each chapter concludes with references for further reading, but in a number of instances more useful references might have been chosen Possibly a fuller bibliographical appendix would have served the purpose better. There are a number of errors which will no doubt be eliminated in later editions The book is described on the cover as a useful student revision text for examination purposes I myself hope that in future more detailed treatment can be given to the section on milk and milk products whereby the book could become a standard text-book for students of dairying

Despite these criticisms, the book has the great merit of providing in compact form a serviceable text in bacteriology for students of dairying and for workers in other food industries and can be recommended to such students It is hoped that the demand will be such as to encourage Dr Seaman to plan a more comprehensive second edition

D A McKENZIE

MEDICINAL CHEMISTRY

Pharmaceutical Chemistry

Plenary Lectures presented at the International Symposium on Pharmaceutical Chemistry held in Florence, 17–19 September 1962. (International Union of Pure and Applied Chemistry in conjunction with the Italian Society of Pharmaceutical Sciences) Pp v+207–492 (London Butterworth and Co (Publishers), Ltd, 1963) 60s

RESEARCH workers in the field of medicinal chemistry should not be deterred by the title, which might reasonably be understood to relate to the art of tablet preparation In fact it contains sixteen up-to-date (mid-1962) reviews, most of which will be found of value to those interested in the mode of action and discovery of drugs Dr Ing has made a most thoughtful contribution with his paper on the interaction of drugs and receptors He stresses the need to avoid acceptance of facile single explanations of drug action This cannot be over-emphasized Dr Ing nevertheless almost falls into the trap himself when he concludes that he is forced to think in terms of an exact fit between the drug and the receptor

Near miracles in the synthesis of medium-sized polypeptides are becoming almost a commonplace when a sufficient number of analogues of a polypeptide hormone can be synthesized to allow a study of structure-activity relationships to point approximately to the active centre Dr. Schwyzer's review of polypeptide hormones, for example, ACTH, oxytocin, angiotensin and kallidin, is masterly, but he, too, sounds a note of caution He appears to reject any suggestion that secondary or tertiary conformations, stable in the solid-state or in solution, are relevant to the biological activity of a polypeptide Dr Hofmann deals in greater detail with two of these hormones, ACTH and the melanocyte-expanding hormone, α-MSH He has established, from the studies of synthetic fragments and their analogues, that full activity resides in the first 20 of the 39 residues of the ACTH molecule and that the Lys Lys Arg Arg unit at positions 15–18, the free terminal α-amino group and all or some of the ε-amino groups of the lysine residues are important

The *cyclo*peptides of the phalloidin group obtained from poisonous mushrooms are substances from the unreal world of D-amino-acids, γ-hydroxy-α-amino-acids and *allo*-hydroxyproline and in which alanine alone is respectably normal Prof Wieland writes a fascinating account of these compounds Not least interesting are his discussion of the additional element of asymmetry introduced by their bicyclic structure and his disclosure that of the two forms of phalloidin, which are thus capable of existence, only one is biologically active

Prof Bovet points to the difficulties in the classification of psychotropic drugs Nevertheless, he provides a useful survey on the basis of the commonly accepted arrangement of the drugs into their various categories With many of the drugs, both stimulant and depressant, their clinical effects, pharmacological properties and, to some extent, molecular structures are in good accord An exception is imipramine, a drug of value in the treatment of endogenous depressions, but similar in structure and in several pharmacological properties to the phenothiazine tranquillizers

From a careful review of the properties of noradrenaline and its *N*-alkyl derivatives, Prof Pratesi asserts that the nature of the "cationic head" decides whether the biological effect be α- or β-adrenergic in character One instinctively feels that this is an over-simplification

Of the remaining contributions to this volume, some of which are purely chemical in nature and might therefore be felt to be rather out of place, specially worthy of mention is that by Prof Prelog on the siderochromes, a remarkable series of iron-containing naturally occurring compounds comprising both antibiotics and growth factors

Although the report of a widely based symposium must inevitably have something of a magazine flavour, this is nevertheless a valuable publication The reproduction of chemical formulæ is of a high standard, and it is with diffidence that the omission of a chlorine atom from each of the structures and prochlorperazine and chlorprothixene is noted. The photographic reproductions are of poor quality.

A F Crowther

A PIONEER IN STATE MEDICINE

Sir John Simon 1816–1904 and English Social Administration.

By Dr Royston Lambert Pp 669 (London Macgibbon and Kee, Ltd , 1963) 63*s* net

SIR JOHN SIMON, who well and truly laid the foundations of State Medicine in England and Wales and successfully combined this work with arduous duties as surgeon on the staff of St Thomas's Hospital, London, forms the subject of this authoritative biography to which Dr. Royston Lambert, Fellow of King's College, Cambridge, has devoted several years of painstaking research and investigation

John Simon, of French ancestry, was born in London on October 10, 1816 His father was a well-to-do stockbroker, and the son was brought up at Blackheath and educated at Dr C P Burney's school at Greenwich After a year's study of German and French in Rhenish Prussia he was apprenticed to J H Green, professor of surgery at the new King's College in London He learned surgery also at St Thomas's Hospital, then in the Borough Simon became a Member of the Royal College of Surgeons in 1838 and a Fellow in 1844 In 1840 he was made senior assistant-surgeon to the new King's College Hospital For a time he hesitated as to his vocation and studied Oriental languages, especially Persian, in the British Museum In 1842 he began physiological and anatomical research work on the thymus and thyroid glands which gained for him the Fellowship of the Royal Society in 1845 In 1847 he became the first lecturer in pathology at St Thomas's Hospital with surgical charge of forty beds By 1853 he was full surgeon and lectured, taught and operated at the hospital until 1876 He was president of the Royal College of Surgeons from 1878 until 1879 His distinction as a leading London surgeon is overshadowed by his achievements in public health

In 1848 he was appointed the first Medical Officer of Health of the City of London In that year he married Jane O'Meara, who was related to Barry E O'Meara, Napoleon's doctor at St Helena In that year also the first Public Health Act was passed, mainly as a result of the work of the medical pioneers, Southwood Smith, Arnott and Kay-Shuttleworth, set forth in Edwin Chadwick's famous *Report on the Sanitary Condition of the Labouring Population, 1842*, and the General Board of Health was established There was pressing need to deal with cholera and smallpox This Board was a triumvirate comprising the First Commissioner of Works, Chadwick and Lord Ashley (afterwards the Earl of Shaftesbury) It did useful work, but in 1854 it was reconstituted with Sir Benjamin Hall, M P , as president and a medical advisory committee, of which Simon was a member The autocratic Chadwick retired on a pension In 1855 Simon became the first medical officer of the Central Health Authority In that year medical officers of health had been appointed for all London districts They included Dr John Burdon Sanderson, Dr George Buchanan, Dr Odling, Dr Parry, Dr. Robert Barnes and Dr T Stevenson, all of whom advanced organized public health Three years later the General Board of Health was abolished Its medical duties, including vaccination, were transferred to the Privy Council and its Poor Law administration to the Home Office In spite of the important work Simon had done for public health, it was proposed to abolish the post of medical officer, and only through the private intervention of the Prince Consort was this retrograde step altered Thus the Privy Council obtained in its medical officer a man of great abilities and wisdom, burning with zeal beneath a calm demeanour to benefit mankind

John Simon was medical officer to the Privy Council from 1858 until 1871, and held a similar appointment under the new Local Government Board from 1871 until 1876. He was Crown Nominee of the General Medical Council, 1876–95, created C B on his retirement and advanced to K C B in 1887' He died from acute bronchitis in 1904

Simon's *Reports on the Sanitary Condition of the City of London* and his annual reports to the Privy Council and the Local Government Board are vivid pictures of social and sanitary evils, and describe the results of important medical researches by the scientists, Burdon Sanderson, Klein, J W Thudichum and others, together with comprehensive investigations into disease and its prevention He broadened the outlook on public health and the prevention of disease, demonstrated that they were an essential aspect of medicine, and was the director and disseminator of new and fundamental knowledge on these subjects

Admirably and fully, Dr Lambert describes Simon's conflicts with the poor law administrators, his frustrations, triumphs, honours and successes He gives an account of the joys and sorrows of his private life

Simon took an unduly pessimistic view of his great life-work, and one minor criticism of the biography is that Dr Lambert might have appreciated more fully the progress made in public health and epidemiology by the medical staff of the Local Government Board after Simon's retirement No less than four of Simon's successors in the post of medical officer had served under him as medical inspectors—Seaton, Buchanan, Thorne and Power They maintained the high traditions set forth by Simon, and preached the hygienic gospel with the fervour of disciples Simon himself stated, on p 414 of his *English Sanitary Institutions* (a historical and philosophical exposition of the history of English hygiene (1890)), that "the very conspicuous ability of the Department under Dr Buchanan as shown in the works and in the administrative advice which the Department supplies, is something of which English Medical Science has every reason to be proud" Afterwards, with the advice and energetic direction of another medical officer of the Board, Sir Arthur Newsholme, the first State social health services were founded

This is a valuable and excellent biography of one of England's greatest benefactors ARTHUR MACNALTY

TREATMENT OF CANCER

Biotherapy of Malignant Tumours

By N G Klyuyeva and G. I Roskin Translated from the Russian by J J Oliver Translation edited by Dr W J P Neish Pp ix+315+132 plates (London and New York, Pergamon Press, 1963) 80*s*

SINCE the early work of Coley at the end of the nineteenth century, reports have frequently appeared suggesting that the growth and development of malignant disease may be modified significantly by certain intercurrent infections or by various microbial products In recent times numerous low molecular weight products of microbiological origin have been isolated, chemically characterized and shown to have carcinostatic properties in animals and in man These relatively simple substances are, however, only part of a much broader spectrum of natural products to the therapeutic use of which the authors of this Russian work apply the general term "Biotherapy" Within this definition they include the use of such diverse agents as viable micro-organisms pathogenic or otherwise, microbial toxins, lysates and filtrates, oncolytic viruses, bacteriophage, yeast and fungal products and related materials of greater complexity and less well defined than the simple carcinostatic antibiotics The preliminary chapters of the book are devoted to brief reviews of these topics, reviews which in many instances are out-dated at the present time due to the six-year delay that has occurred between the publication of the original Russian text and the appearance of its translation

A primary object of this book is to present the experience that the authors and their clinical colleagues accrued over the period 1946–57 in the use of *Trypanosoma cruzi* extracts (cruzin) in the treatment of human cancers, particularly of the lip and breast This they have done by way of detailed case reports supplemented in the English translation by a selection of the results obtained more recently by French investigators utilizing similar *Trypanosomal* products The authors claim that complete regression can be induced in a proportion of human malignancies of various types and localization by prolonged administration of the extracts and that the treatment can be effective against primary, secondary and recurrent growths with no detectable pathological effect on the function or structure of normal tissues In cases of advanced inoperable disease, a transition to an operable condition may occasionally arise and likewise, where possible, surgical intervention during the course of treatment may accelerate the process of oncolysis

In subsequent chapters the authors describe the histological and cytological changes induced in malignant tissues of both human and animal origin under the influence of *T cruzi* extracts They describe a complex series of changes in the growth characteristics of tumour tissues in which the cells undergo progessive diminution in nuclear and nucleolar sizes, in mitotic activity, in ribonucleic acid content and protein synthesizing ability They believe that this process of 'normalization' and 'loss of aggressiveness' leads to the establishment of a new relationship between erstwhile malignant tissue and the normal body defence mechanisms Subject to the degree to which this process can be established, there follows a subsequent reaction in which the tumour region is invaded by cells of the reticulo-endothelial system leading to the destruction of tumour cells and their replacement by connective tissue as the final act of the carcinolytic process where this goes to completion

To the experimentalist, it is perhaps unfortunate that much of the earlier work leading to the present clinical investigation was published in a volume under the same title by the authors in 1946 and will not be readily available to Western investigators Nevertheless, the present observations are of interest to oncologists generally, particularly to those interested in the immunological aspects of cancer C L LEESE

TRENDS IN CANCER RESEARCH

Advances in Cancer Research

Vol 7. Edited by Prof Alexander Haddow and Sidney Weinhouse Pp ix+599 (New York Academic Press, Inc , London Academic Press, Inc. (London), Ltd , 1963) 128*s* 6*d*.

Canadian Cancer Conference

Proceedings of the Fifth Canadian Cancer Research Conference, Honey Harbour, Ontario, June 10–14, 1962 Edited by R W Begg, C P Leblond, R L. Noble, R J. Rossiter, R M Taylor and A C Wallace Pp xii+479 (New York Academic Press, Inc , London Academic Press Inc (London), Ltd , 1963) 100*s*.

THE present volume of *Advances in Cancer Research* contains seven chapters Beard discusses at considerable length our present knowledge of avian virus tumours, while Negroni, in a shorter chapter, presents information about rabbit and mouse tumour viruses as well as chicken tumour viruses and 'passenger' viruses, such as Riley's Agent In a long chapter, Brockmann deals with the mechanisms of resistance to anti-cancer agents, and questions of cross-resistance and collateral sensitivity in cancer chemotherapy are considered by Hutchinson. These chapters should be of considerable interest to workers directly concerned with virus tumours and chemotherapy

Of more general interest perhaps is an analysis by Kotin and Falk of the contribution of atmospheric factors in the pathogenesis of cancer of the lung Farber has surveyed the carcinogenic properties of ethionine and concludes that its activity may be due to its ability to produce altered DNA and/or RNA within the cell At last, according to Farber, there is some factual support for hypotheses that altered chromosomal or extrachromosomal nucleic acids play a key part in cancer production In a short chapter, Court Brown and Tough present the interesting work of their group in Edinburgh and of a group of workers in Philadelphia on the discovery of an abnormal chromosome Ph^1 in the marrow cells of patients with chronic myeloid leukæmia This specific chromosomal abnormality seems to be closely connected with the primary cause of the disease

Volume 5 of the *Canadian Cancer Conference* presents sets of papers devoted to cellular organization, cell interaction, immunology and chemotherapy The scope of this work is more general than that of the present volume of *Advances* and it will probably appeal to a wider audience of cancer workers

In the section on cellular organization, consideration is given to the mode of formation of polypeptide chains and to the comparative molecular biology of virus and cellular nucleic acids Autoradiographic investigations which deal with the sites of ribonucleic acid and protein synthesis in the cell are presented, and Ochoa discusses the nature of the genetic code Interaction of viral ribonucleic acid with mammalian cells is described, and Leslie deals with the control of gene expression which may be influenced by histones In an interesting discussion of chromosomes and carcinogenesis Stich concludes that a genetic concept of cancer must be given consideration, but the question still remains as to whether chromosomal changes in early neoplasia are cause or consequence of cancer formation

Ford and Clarke present evidence of clonal proliferation in primary reticular neoplasms (compare chapter by Court Brown and Tough in *Advances*)

Another topic of present interest in cancer research is that of cellular interactions This section deals with cellular interactions *in vitro*, describes an attempt to determine the time of mitosis in relation to ribonucleic acid and deoxyribonucleic synthesis and contains a discussion of a subcellular agent which produces ascites tumours in mice Daoust has contributed a chapter on pre-neoplastic liver parenchyma in which the idea again emerges that changes in nucleic acids may represent essential steps in carcinogenesis The section is concluded with a discussion of cell interactions by Weiss

Immunological aspects of cancer research are considered in seven chapters which deal with acquired immunological tolerance, auto-antibody formation, immunity to virus-induced tumours, etc , and, in the final section, chemotherapy, mechanisms of resistance to antimetabolites are described as well as cross-resistance In the final chapter Burchenal surveys the problems in clinical resistance

These two volumes from Academic Press are valuable additions to their respective series They seem to point the way to proliferation of research in the region of chromosomal and nucleic acid abnormalities which may prove to be at the very root of the carcinogenic process

W. J P Neish

DETECTING BLOOD DISORDERS

Atlas de Thrombodynamographie

Par G Marchal, M E Leroux et M Samama Pp 186 (Paris. Service de Propagande, Édition, Information, 1962) 60 N F

THE authors have produced a comprehensive atlas to illustrate the various changes they can measure in certain blood disorders using the thrombo-elastograph as designed by Dr Hartert

This ingenious piece of apparatus records on film the oscillations of a light beam reflected from a mirror mounted on a torsion wire On this wire is suspended a plunger which is immersed in whole blood or plasma contained in a stainless steel cuvette The latter oscillates regularly 5° on either side of the midline, and as the blood or plasma clots naturally or after the addition of calcium, the fibrin formed grips the plunger and so transmits the movements of the cuvette to the film The trace on the film records the time it takes for fibrin to appear first, the rate of fibrin formation and the gripping force of the fibrin formed

The details of the apparatus and the technique of operating are described in detail together with a useful description of artefacts that may be encountered The sequence of blood coagulation and the role of each plasma factor and platelet function are discussed and illustrated Tracings to show the different patterns obtained in certain disorders are also reproduced, namely, thrombocytopenia, abnormalities of platelet function, fibrinogen deficiency, plasma coagulation factor deficiencies, circulating anti-coagulants, prothrombin deficiency, fibrinolysis, hyper-coagulable states, and anticoagulant-induced defects. The authors illustrate and describe adaptation of the thrombo-elastograph technique to define specific coagulation defects and also the use of this machine in defining the changes in the blood following open-heart surgery

There is a very comprehensive text accompanying the illustrations, and the publishers are to be congratulated on printing this in French, English and German It is a pity that more care has not been taken with the English text, which is quaint and in parts frankly misleading due to the translation being too literal Further, the authors can be criticized for trying to convert this into an incomplete text-book on hæmorrhagic diseases

A shorter text confined specifically to the problems and value of thrombo-elastography would have been more acceptable An unusual feature is the mixture of advertisements with the bibliography, which is incomplete Authors' names in the text are not designated by the dates of their articles and some authorities quoted in the text are not mentioned in the list of references

Although there are these defects, this book should be read by those who have, or contemplate having, this instrument to assist in the problems of routine diagnosis or for research purposes A A Sharp

SOUTHERN NIGERIAN ANTHROPOMETRY

The Physical Anthropology of Southern Nigeria

A Biometric Study in Statistical Method By the late P. A Talbot and H Mulhall (Occasional publications of the Cambridge University Museum of Archæology and Ethnology) Pp xvi + 127 (Cambridge The University Press, 1962) 32*s* 6*d*

THIS monograph was made possible by the late Dr P Amaury Talbot, former resident, Civil Administration, Southern Nigeria, who for thirty years collected anthropometric and anthroposcopic data in this region which he administered After his death, Mrs Talbot put the data at the disposal of the Duckworth Laboratory of Physical Anthropology, Cambridge, the director of which, Dr J C Trevor, further sought the statistical help of Dr Mulhall It has been the latter author's task to reduce the mass of undigested data to the meticulous and precise analysis seen in this published work

The first chapter is understandably devoted to previous regional classification of Southern Nigeria and the relevant population numbers (although, incidentally, the sample sizes utilized in the analysis are not relative to the population totals for the regional groups) This is followed by a diversion into statistical procedures, Chapters 2–7, which are meant as a general introduction to anthropometric statistics, as well as to the final detailed analysis Mulhall is to be congratulated on the way in which he carefully takes us through the statistical methods, problems of sampling, probability and theoretical distribution models, statistical relationships, and problems of group divergence

The original contribution of this book is in its analysis of the measurements of nearly 7,000 inhabitants from more than 50 groups Although there is some debate as to the relative merits of an exhaustive analysis of a few dimensions (12 in this case), as opposed to the less-detailed analysis of more measurements, one is left wishing that a few more had been available

This analysis of the Nigerian data forms the last two chapters First, the body measurements are considered, culminating in the computation of D^2 values for all the regional groups This is followed by a consideration of skin colour (alas, Talbot was recording in the days before colorimetric scales and the portable spectrophotometer were in use) This pigmentary information is a useful addition to the study, and in part corroborates and in part challenges the conclusions drawn from the metrical investigation Finally, there is a reclassification of the groups analysed

As Trevor and Mulhall intended, this is a survey of statistical methods in some aspects of physical anthropology, combined with a detailed analysis of data from one area of West Africa—a somewhat unique combination

A final chapter reviewing the results of this analysis in relation to other human biological findings from Nigeria (serological, dermatoglyphic, etc) would have been a very useful addition Also, perhaps some mention could have been made of possible environmental differences between the groups (climatic and especially nutritional) As certain abnormal hæmoglobin deficiency traits, relatively common in Nigeria, can also affect body dimensions, it would have been interesting to have these brought into a general discussion as well.

In view of the fact that photographs were taken by Talbot (presumably in standard positions), it is a pity that a representative sample was not included Some may consider the lack of an index a serious deficiency, although the monograph is not so long that this becomes a cumbersome problem D. R Brothwell

AMATEUR SOCIOLOGIZING

Conference Across a Continent

(An account of H R H the Duke of Edinburgh's Second Commonwealth Study Conference on the Human Consequences of the Changing Industrial Environment in the Commonwealth and Empire, Canada, May 13–June 6, 1962 Pp. 521 + 104 photographs (Toronto Macmillan of Canada, London Macmillan and Co , Ltd , 1963) 40*s* net

In 1956 a study conference, inspired by H R H the Duke of Edinburgh, was held at Oxford on the human problems of industrial communities within the Commonwealth and Empire This proved to be so successful, especially to the Canadians who attended it, that a second study conference was organized in Canada during May 13–June 6, 1962 Both conferences have taken the same general form, documents and papers were circulated beforehand, lectures were given to the assembled participants, discussion groups were formed to consider the material presented, study tours were arranged to different kinds of industrial communities in the country where the conference was held, and the conference reassembled eventually to discuss experiences and the reports of the several study groups There can be scarcely any doubt but that on both occasions the participants were worked hard, enjoyed themselves enormously, and returned home feeling that the experience had broadened their outlook and that they had learned something of importance. It is open to question, however, whether anything beyond the emotional and intellectual stimulation of the participants is achieved by programmes of this nature

From the point of view of one who attended neither conference and has only the published reports of the proceedings to judge them by, the Canadian Study Conference must be reckoned inferior to that held in Britain Whereas in 1956 twenty-four 'background' papers have been reprinted[1], many of them of excellent quality, only six appear to have been circulated on this later occasion in *Conference Across a Continent*, and none of these is outstanding Of course, Canada is a very large country, and the conference was regularly on the move, from the opening in Montreal to the closure in Vancouver, so that apparently more time was devoted to the study tours than was the case previously, but surely this is not a good reason for failing to circulate and to reprint investigations into the human consequences of the changing industrial environment of Canada which could make a contribution to our knowledge of these matters

The sociologist, indeed, might well complain that the emphasis on touring 'study groups' is misplaced What real knowledge of a very complex situation can such groups obtain in so short a time? The report of the Canadian study tours claims that the groups were capable of generating a "dynamic" that was "almost overwhelming" Conceivably, many of those who were caught up in this "dynamic" underwent a change in their manner of looking at the social environment But there is always a serious danger in such a circumstance that the individual concerned will mistake this experience for understanding As the report itself acknowledges, "the social process known as group dynamics can lead to a construction of worth-while design or to a pooling of ignorance" (p 69) Only if the group is trained beforehand in the techniques of social enquiry is it likely that it will make reasonably precise and objective discoveries There is no evidence on this occasion that the enthusiasm of the amateur was guided away from hasty generalization through the employment of the expert methodology of the professional

Consider, for example, a question listed in the discussion sheets which were provided as part of the study-tour programme as a guide to what might be 'usefully asked' of local informants—"Do many in the community think that some families prefer to draw unemployment insurance rather than work?" (p 478) This is apparently a quantitative question, involving at least two numerical variables, for which in principle there are precise answers. Were the conference members told about how such answers are obtained in a modern social survey? Were they made aware that a sampling procedure, utilizing statistics and at least a rudimentary notion of the mathematical theory of probability, is used, and is to be preferred, for good logical reasons, to the casual guesses of the man-in-the-street who believes he knows what his friends and neighbours think? Were they given any instruction at all which could help them to distinguish between the prejudices of one informant and the empirically based knowledge of another? Apparently not, for the list of questions themselves were regarded by some of the conference members as a strait jacket As one of them put it, "if these questionnaires had not been prepared, the group reports might have had more individuality and thrown light on subjects which may have been omitted" (p 76) No one seems to have stopped to ask him the crucial question—"But what sort of light?"

It cannot be too often reiterated that the study of the human consequences and social implications of technical and industrial change is beset by logical pitfalls and methodological difficulties of considerable complexity A survey of research in this area, presented to a conference sponsored by the International Social Science Council in 1959[2] pointed out that far too often expert social historians, economists, sociologists, social psychologists and social anthropologists leap to conclusions which are, as a matter of fact, not supported by the data in their investigations If this is so of the professional, how much more likely it is that the untrained amateur will be led astray by his enthusiastic desire for quick results! This should not be taken to imply that there is no place for the amateur in contemporary social science Of course there is, just as there is still some place for the amateur in astronomy, and even to some extent in nuclear physics But the part to be played by such people is clearly dwindling, and they can make no contribution except in so far as their enquiries can be fitted into the framework of established theory in these subjects

Nor should it be assumed that conferences such as these, bringing managers and trade unionists together from all parts of the Commonwealth and Empire, are valueless A few weeks of extensive travel and intensive intellectual and emotional stimulation make an impact on the participants which is not quickly eradicated Useful contacts and firm friendships are established, and the published reports serve not only to awaken recollections of a collective experience but also as a directory for future communications Such conferences also act to freshen psychologically people who have become a little dull in their pursuit of the everyday, industrial routine, and if they learn in the process that people accustomed to very different ways of life can nevertheless get along well together, so much is to the good The pity is that one of the aims of such conferences—the Duke of Edinburgh's idea, "to give them a chance to take a broad view of their responsibilities during the process of industrialization or during the further development of existing industrial communities" (p 21)—should have become clouded by failure to teach them the lesson of contemporary social science, namely, that the painstakingly acquired tools of social investigation are better utilized for this purpose than the traditional rule of thumb.

J. A Banks

AFTER THE SCIENTIFIC REVOLUTION

Inventing the Future

By Professor Dennis Gabor Pp 231 (London Secker and Warburg, Ltd , 1963) 21*s* net

WE should have realized a long time ago that it is really P G Wodehouse's Bertie Wooster who is riding the wave of the future, and that barring accidents the widely acclaimed disappearance of the Leisure Class looks like being followed, after only a very few years, by an overwhelming comeback The Age of Plenty is already dawning and, although at its first appearance, we are tempted to greet it as cheerfully as people who have spent a long cold night out of doors see the first rays of the Sun, we are already beginning to realize that by mid-day it's going to be a real scorcher No need to work, no diseases, no need to read, travel from any part of the globe to any other within a few hours—how in the world are we going to fill our time ?

Of course, in those old best-sellers whenever the sheer vacuity of Bertie Wooster's perennial leisure had led him into some particularly disturbing piece of mischief, he turned for advice to his ever-capable and far-sighted manservant Jeeves Dr Gabor has set himself nothing less than the task of playing Jeeves—and this time one who has first-rate scientific expertise at his fingertips—to the whole leisured world of the future An extraordinarily good job he makes of it This is a short book, only 190 pages of text and about another 30 of notes There are very few scientists, and practically no reasonably educated non-scientists, who would not get great profit from devoting to its reading the few hours which is all it demands On almost every page there is something which, if not always entirely novel, is put into a way which is fresh and thought-provoking and often witty

A great number of these points, of course, call aloud for discussion The book is so compressed that it is impossible to summarize all the numerous arguments it contains, or to indicate particular points of agreement or doubt In the broadest possible outline the main framework is made by the three major problems which mankind now faces of nuclear annihilation, of being swamped by a flood of babies, and of being bored to death About the first two Dr Gabor shows a robust, and reasonably convincing, optimism The equilibrium in the balance of nuclear power is, as he points out, a remarkably stable one as between the United States and the U S S R , and probably strong enough to absorb the potential threat of China long enough for that country's crusading ardour to die down to a manageable level The population explosion is perhaps more challenging, but technological advance in the production of foodstuffs is, or could be, rapid enough to give us a certain breathing space From a moderately long-term point of view there are clearly several ways in which the human birth-rate could be controlled, many of them involving social influences on individual behaviour which we, our generation, might find difficult to stomach but which our successors may easily take in their stride There is, after all, an extraordinary capacity for homœostasis in almost all biological systems, and if *Homo sapiens* succeeded in breeding itself out of a livelihood this is something almost no other species has been able to accomplish.

It is when he turns to the problems of an age of leisure and plenty that Dr Gabor becomes most stimulating I can perhaps best indicate the character of the book by a few quotations "Between 1947 and the end of 1961 the U S work force had expanded from 60 million to 71 million, but the total number of production line workers had decreased by 7 per cent . They have a good conscience, working so hard at their telephones and typewriters or rushing from one place to the other for urgent conferences This is just the wonderful thing in this modern system of waste that it makes people believe that they are useful" (pp 109, 110) " as C E M Joad said 'Work is the only occupation yet invented which mankind has been able to endure in any but the smallest possible doses' The truth is rather that in a country in which the economic game is played passionately, this threatens to produce a dull conformity, the very opposite of freedom" (p 135) "Stagnation, at whatever level remains an ugly word to intellectuals who have grown up in an epoch of material progress" (p 135) "In the first years of childhood probably not much harshness will be needed to educate citizens for the age of leisure but there can be little doubt that hardship will be a necessary component in the education of the adolescent" (p 138) "Western object-mindedness and work addiction is one extreme, Eastern quietism and introversion is another . . We must not give up hope that we shall be able to assimilate something from the East which will be better for the restless Western mind than alcohol or opium" (pp 140, 141) "There is no limitation to the number of those who can enjoy science other than their own ability to comprehend it My idea of the amateur scientist is that he shall be a *knower* not a *doer*" (p 144) "Certainly, the masculine valuation of strife and progress has created our civilization, it will just as certainly destroy it if it goes on much longer unmitigated by feminine principle" (p 149)

This last quotation brings me to the one point of criticism I should like to make of this book It is, in some rather indefinable way, a peculiarly impersonal work, rather like an engineer's rough drawings trying out a series of ideas for some major design I find it difficult to pin down exactly from where the impression arises; possibly from the fact that Dr Gabor scarcely mentions religion or any activities related to it, possibly again from the fact that although he values something that he refers to as a "feminine principle", he does not mention sexual activity and indeed scarcely refers to inter-personal relations, although surely religion, sex and personal relations have always in the past filled the greater part of the lives of those few individuals who have enjoyed ample leisure However, few people will—and I am sure the author would not expect them to—read this book in order to be told exactly how to solve the problems of the future What they will find in it is a most provocative list of problems with which mankind is likely to be confronted, and a large number of positive and buoyant suggestions for some of the things we might do about them

C H Waddington

THE FLOODTIDE OF MANKIND

Our Crowded Planet

Essays on the Pressures of Population Edited by Fairfield Osborn (Sponsored by The Conservation Foundation.) Pp 192 (London George Allen and Unwin, Ltd , 1963) 21*s* net

THIS volume, sponsored by the Conservation Foundation, comprises a series of twenty-one specially commissioned essays from authors of international fame long associated in their writings with varied aspects of the population problem In a brief introduction by Fairfield Osborn, we are reminded that the "inordinately rapid increase of populations . . faces everybody everywhere" The essays are all short, ranging from a little more than a thousand words to about five thousand, and one could scarcely expect anything new to be said in so restricted a space. There is, obviously unavoidably, a great deal of repetition most essays give figures for world population and rates of increase which vary considerably, and all are out of date according to the present issue of the *Demographic Yearbook of United Nations* Internal evidence suggests that some of the essays were written several years ago when the world's population was, according to p. 183, 2 75 'billion' [U S billion], increasing by nearly 50 million a year at more than 1 5 per cent That the present-day figures are 3 2 billion, 63 million a year and more than 1 9 per cent only serves to emphasize how we are, in fact, being overtaken by events, and gives point to the comment of Sir Charles Darwin (there is no indication of his death) that we are living "in what is a fantastically abnormal period of history and one which must inevitably end soon . the end to such things as affluent societies and welfare states, and our descendants will look back to the nineteenth and twentieth centuries as a golden age of easy life"

The essays are arranged in five groups Five in the first deal with population pressures on man's natural environment, and it is not difficult to guess the lines taken by Marston Bates, Darwin, Paul Sears, Frederick Osborn and Fraser Darling Marston Bates, with others later in the book, reminds us that the human animal evolved as part of the world biological system, he has become an "ecological dominant", and there must inevitably emerge some "wise principle of co-existence between man and nature" to end "his present cancer-like spree of reproduction" We are constantly reminded in these essays, indirectly rather than of purpose, of the isolation of the United States where the 'modern commoner thinks nothing' of an escort of a thousand slaves (that is, a motor-car developing 100 horse-power) (Sears), but where "many social workers to-day would lose their jobs if they were caught giving contraceptive advice" (Osborn) It is Osborn who brings out the advantages of "assortative mating" consequent on greater mobility, otherwise the inevitable trend of mankind using modern medical skills is the reverse of selective breeding among animals Osborn concludes that "public health authorities will some day accept responsibility for genetic defect as they now accept responsibility for controlling contagious disease"

Part 2 has seven essays dealing with population pressures on economic and political trends by Eugene Black, Earle Rauber, Lord Boyd Orr, Sir Solly Zuckerman, H S Commager, Grenville Clark and Arnold Toynbee In each case the author puts forward views already associated with him. Eugene Black tends to highlight the differences between the economist's and the scientist's basic thinking, though he too concludes, "unless population growth can be restrained we may have to abandon for this generation our hopes of economic progress in the crowded lands of Asia and the Middle East" At the same time he is not convinced that population growth will eventually outrun the development of the world's resources Lord Boyd Orr has been converted to the optimistic belief that "the present explosion of population is merely the birth throes of a new age of stabilized population in a world of peace and plenty" To this Sir Solly Zuckerman adds, "the problem of population pressure becomes simply a problem of politics and leadership", and Arnold Toynbee looks to a new and permanent United Nations Relief and Rehabilitation Agency to achieve world unity for production and distribution of food

Four important essays, making up Part 3, supply a valuable corrective to world generalizations by presenting case studies of India (M C Chagla), Japan (Chikao Honda) and Latin America (E Beltran) with the veteran W C Lowdermilk drawing on his wide experience in the less-developed lands Independent India in 1947 planned for a population in 1961 of 430,000,000, actually it reached 438,000,000—"a dark and dismal future for millions, bitterness and frustration, poverty and unemployment, political discontent and unrest" Voluntary sterilization, described as simple, painless and free, is advocated The miracle of Japan's population change with the 1957 natural increase of 0 887 per cent, the lowest ever recorded in Japan's modern demography, is attributed to conscious planned parenthood, but there is some doubt as to its permanence

The two essays on the population problem and religion are unsatisfactory. Bishop J A Pike of California, as a Protestant, attacks the 'official' Roman Catholic attitude which Father Robert Gannon, former President of Fordham, calls a "monolithic illusion" It is left to Bates to comment that inoculation is as 'unnatural' as contraception Finally Joseph Wood Krutch, André Maurois and Julian Huxley are left to consider population pressures on morals and ethics André Maurois is in no doubt of the terrible retrogression since 1914 basically due to the wild proliferation of men bringing forth unintelligent generations, and calls for a reversion of the tide. The history of mankind records examples of such great reversions. Christianity is one Julian Huxley looks to "the vision of evolutionary humanism, essentially religious", and we should devote ourselves with truly religious devotion to the cause.

A well-selected list of general and technical readings concludes this interesting collection, which, if it contains nothing new, summarizes in convenient and readable form the considered views of twenty-two leading thinkers It is most unfortunate that the publishers should print the names of sixteen of these on the dust cover, unhappily leaving out six authors, all non-British, who in fact have the most valuable contributions to make In the cause of international understanding this dust cover should be withdrawn at once

L DUDLEY STAMP

THE UNITY OF LIFE

The Unseen World

By Prof René Dubos Pp xi+112 (New York The Rockefeller Institute Press, London Oxford University Press, 1962) 35s net

In a foreword to this book, Detlev W Bronk explains that the Rockefeller Institute has decided to initiate an annual series of lectures similar to the famous Christmas Lectures at the Royal Institution This is welcome news, because there can be few establishments in the world with such a distinguished staff of scientists Dr Dubos is a microbiologist of international repute, and so well has he succeeded in presenting his subject that it is bound to fire off the imaginations of many young people, as yet undecided on their future careers The remarkable thing about this beautifully produced book is that it touches on so many interesting aspects of biology in so short a space. If it manages to send a middle-aged and somewhat blasé reviewer scurrying over to the library to find out more about lichens, cheeses, orchid seeds, the colour of tulips and the production of hæmoglobin in root nodules, it will surely capture many a young reader

Throughout the book one senses that Dr Dubos has a deep feeling about the fundamental similarity of different forms of life Many biochemical processes in micro-organisms are identical with those in higher animals and are often easier to investigate The electron microscope is beginning to show that there are also fundamental structural similarities The mitochondria of yeasts are not very different in form from those found in higher plants protozoa and man Even where apparent differences exist we now realize that these are often only modifications of a basic design The buildings may look different, but the bricks are similar. The association of enzyme system with various membranous components of the cell is well established, and it may be that mutations and adaptations in response to unusual environments are accompanied by ultrastructural changes. If so, micro-organisms would seem to be the best experimental material for this type of investigation. One must agree wholeheartedly with Dubos's statement "The biophysical and biochemical unity of life is certainly one of the largest contributions of modern science to philosophical thought".

In so short a book it is inevitable that some topics are discussed inadequately. There is an occasional loose statement, as, for example, in discussing Pasteur's work ". . . he found that one solution deviated polarized light to the right and the other to the left", but one sympathizes with the difficulty of trying to explain polarized light to a general audience. The section on antibiotics is very brief, and the birth dates of Florey and Chain are unfortunately interchanged. It is perhaps a pity that space could not be found for the contributions of John Tyndall, himself closely associated with the Royal Institution. His *Essays on the Floating Matter of the Air* published in 1881 are an excellent example of clear thinking and he must surely rank among the great pioneers of biophysics and microbiology. Not only did he observe the antagonism between some moulds and bacteria but he stressed the importance of species differences. In describing the contamination of bacterial cultures by *Penicillia* he writes "In every case where the mould was thick and coherent the Bacteria died, or became dormant, and fell to the bottom as a sediment . . . The turnip-infusion, after developing in the first instance its myriadfold Bacterial life, frequently contracts mould, which stifles the Bacteria and clears the liquid all the way between the sediment and the scum . . . The Bacteria which manufacture a green pigment appear to be uniformly victorious in their fight with the Penicillium". So near, yet sixty years too far. Dubos's book makes us wonder what great discoveries are being missed to-day.

R. Barer

ESSAYS OF GEORGE SARTON

Sarton on the History of Science

Essays by George Sarton. Selected and edited by Dorothy Stimson. Pp. xvi+383. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1962.) 80s. net.

GEORGE SARTON, first professor of the history of science at Harvard, died in 1956. For many years he had been one of the leading authorities on his subject, and the editor of this collection of his essays claims that for forty years his name was "practically synonymous with the history of science". So far as the United States is concerned, this statement is unlikely to be challenged.

Sarton was a man of great erudition, an exact and exacting scholar, to which accomplishments he coupled immense energy. He is probably best known as the founder of the international journal, *Isis*, devoted to the history of science, which he edited for some forty years, and to which he regularly contributed a valuable critical bibliography on the history of science and related subjects. He was, however, a prolific writer and, apart from his editorial work, was the author of a number of books and of numerous essays and articles on various aspects of his subject. Before his death, Sarton drew up a list of those among the latter that he considered worth re-publishing. All but three of the twenty-three articles included in *Sarton on the History of Science* were included in this list. Thirteen were published originally in *Isis*. The remainder appeared in a variety of publications for the most part not easily accessible. The selection has been made, and the articles edited, at the request of Sarton's literary executors, by Prof. Dorothy Stimson, whose name may be familiar to British readers as the author of *Scientists and Amateurs*, a short history of the Royal Society.

The essays have been arranged in three groups to illustrate the varying aspects of Sarton's work. Those in the first group emphasize his activities as propagandist for the study of the history of science, and among them is the last important article he wrote, an essay on the history of science contributed to the *Encyclopedia Americana* in 1956. Those in the second group illustrate his work as a historian of science proper. They are mainly biographical, and the subjects chosen range from an essay on Avicenna to one on the work of the twentieth-century scientist, H. C. J. Mosely. A long article on Leonardo da Vinci, not hitherto published in full, is included. The third group has been selected to illustrate Sarton's methods and procedure as a writer and editor. In this section there are articles on such diverse subjects as English as an international language, notes on reviewing learned books, the study of early scientific text-books, and the history of twentieth-century science.

Apart from the value of some of these essays as source material, for example, that on the sixteenth-century Belgian scientist Simon Stevin, this book forms a readable introduction to Sarton's work as a whole. As such it ought to be welcomed by British students of the history of science to whom his contributions to the subject are possibly not as well or, at least, as fully known as they deserve to be.

HOMAGE TO GEORGE PÓLYA

Studies in Mathematical Analysis and Related Topics

Essays in Honor of George Pólya. (Stanford Studies in Mathematics and Statistics, No. 4.) Edited by Gabor Szego, Charles Loewner, Stefan Bergman, Menahem Max Schiffer, Jerzy Neyman, David Gilbarg, Herbert Solomon. Pp. xxi+447. (London: Oxford University Press, 1962.) 80s.

PAPERS from sixty notable mathematicians testify to the respect and, more, to the affection in which Prof. Pólya is held by the contemporary mathematical world. His high professional competence is shown by an output of more than 200 research memoirs, the lucidity of his exposition is known to his readers as well as to those fortunate enough to have heard him lecture. But this is not all; every teacher of mathematics, every young research worker in the field of analysis, can find inspiration and assistance in those of his books in which he has dealt, explicitly or implicitly, with the modes of mathematical discovery and creation. In the middle 1920's, Pólya (in collaboration with Szego), in the two volumes of *Aufgaben und Lehrsatze aus der Analysis*, offered the young analyst a remarkable opportunity of sharpening the tools of his trade by studying the grouped sets of problems (with solutions) on most topics in analysis from the fundamentals of limit theory to complex variable and the analytic theory of numbers; here the novice could see how general theorems could be applied and sharpened in applications to special problems.

After the Second World War, Pólya began writing on the motivation and presentation of mathematical discovery. He emphasized the part played by intuition (perhaps better described as controlled guess-work), a part as important as that played by strict logical inference. Great mathematicians such as Gauss have delighted in publishing their discoveries in concise synthetic form; in recent years, research memoirs have been compressed to extremes in response to editorial demands for economy of space. The young student may marvel at the results, but he will not easily see how they were arrived at. In his books *How to Solve It* (Princeton, 1946) and *Induction and Analogy in Mathematics* (Oxford, 1954), Pólya shows by an opulent variety of examples how a mixture of inductive and analogical argument can lead not only to the conjectural theorem but also, often enough, to the lines on which a deductive proof may be founded. Take, as an example, Carleman's theorem, that if each a_n is positive

$$\Sigma(a_1a_2 \ldots a_n)^{1/n} < e\,\Sigma a_n$$

where, on the right, e is the best possible constant. Pólya's proof of this in the *Proc. London Math. Soc.* (24; 1926) may strike the casual reader as a *tour de force*, but the author's own dissection of his proof shows how naturally the argument flows from a plausible line of approach. Much of the work is within the limits of a good school course, and teachers who make use of his ideas need no longer fear that reluctant intellectual assent ('You've proved it, but I still don't believe it'), which is so often their meagre reward. Pólya has shown us how to convince our students that mathematics is as exciting, as imaginative, as æsthetically satisfying as any other field of intelligent enquiry. Britain needs more mathematicians; it will not get them by stressing utilitarian values, but it may get them by presenting Pólya's view of mathematics as a superb intellectual adventure.

MATHEMATICS IN THE U.S.S.R.

Recent Soviet Contributions to Mathematics

Edited by Dr. J. P. LaSalle and Dr. S. Lefschetz. Pp. viii + 324. (New York and London: The Macmillan Company, a Division of the Crowell-Collier Publishing Company, 1962.) 8.75 dollars, 66*s*.

THOSE who cannot make a direct study of Russian mathematics, because of linguistic deficiency, may find difficulty in assessing the true worth of its immense productivity. To help them, a panel of well-known American mathematicians has devoted a year to an intensive survey of Russian mathematical output, principally for the period 1957–60, and has now reported on some major topics in pure mathematics. The main headings are algebra, control and stability, functional analysis, numerical analysis, ordinary and partial differential equations, probability and information theory, and topology.

The editors have themselves added to the special reports a 'general appraisal'. The conclusions they draw are well worth consideration. While they regard the United States and the U.S.S.R. as world leaders of about equal strength, they believe that the U.S.S.R. can move more rapidly than the United States in the practical applications of mathematical theory, and may possibly surpass the United States in such matters as control theory, numerical analysis, and differential equations, perhaps because of the intense drive by the U.S.S.R. towards automation in industrial production. They emphasize that while the gap in the United States between mathematics and its applications is widening, mathematicians in the U.S.S.R. are not neatly segregated into the 'pure' and 'applied' categories; there, mathematicians, scientists and engineers work closely together, so that, for example, there are many engineers who understand and exploit the most recent of advanced mathematical techniques. Mathematicians themselves enjoy a high prestige and status. Excellent books are available at very low prices, the large number of mathematical periodicals means that room can be found for long expository articles as well as for the highly condensed specialist-to-specialist research memoirs. It is this breadth of view, coupled with motivated specialization, which accounts for the fact that in control theory the quality of work is as good as that in the United States while the quantity and number of participants is much greater, and that in the field of differential equations the lead is now indisputably with U.S.S.R. On the other hand, this may explain why certain topics are under-developed; Lefschetz, in his own report on topology, suggests that the reason why there has been no significant contribution to modern algebraic geometry in the U.S.S.R. is that the subject is self-contained and has no direct influence on applications to applied problems.

This appraisal gives the impression that the Russians have solved the problem of combining breadth of view with sharpness of specialist penetration in a mode which is no longer common in the United States or in Britain. How has this been done? Is Britain's examination system partly to blame? The old Tripos, with its many defects, at least knew no distinction between pure and applied mathematics. J. J.'s first paper was on the theory of numbers, A. R. Forsyth's on hydrodynamics. One thing seems certain: it is not enough for academics, industrialists or politicians in Britain to talk glibly about the need for more mathematicians, it is necessary to look to the kind of mathematicians that are wanted. Britain must have expert pure mathematicians who nevertheless do not despise the stimulus of application, and applied mathematicians who can exploit the most abstract and general theories of the pure mathematician.

T. A. BROADBENT

ATTITUDES IN INDUSTRY

Industrial Participation

Theory and Practice—a Case Study. By J. A. Banks. (Social Research Series.) Pp. 150. (Liverpool: The University Press, 1963.) 25*s*. net.

THE problem of getting employees at all levels in a business organization to participate in its smooth running is one which is frequently posed and seldom solved. In a case study of a factory employing some 500 male manual workers, J. A. Banks has attempted to discover the forces which influence participation in different departments of the factory, among employees with varying periods of service in the particular company, and on different shifts. As a measure of participation he uses the desire to seek promotion to the rank of supervisor, the willingness to seek responsibility by serving as a shop steward, and the extent to which employees were not only prepared but also actually participated in the company's formal joint consultation machinery.

The conclusions are not unexpected and confirm earlier studies of a similar nature. What matters most in influencing the degree to which employees are prepared to contribute to an organization's well-being is not the mechanics of joint consultation, not its technical efficiency, and not necessarily its social groupings. It is, quite simply, the inter-personal factors which continue to make an employee feel he is or is not wanted.

This is the essence of a study which takes a long time in the telling and which, throughout, bears an air of unreality. This is mainly because the statistical analyses are too small to command anything like the general import which Banks indicates and because of his excessive preoccupation with them. The author's lack of awareness of what is happening in industry is indicated in a reference to promotion. "Although there are signs," he writes, "that at the management level recruitment from outside is gradually replacing promotion from within, at the supervisory grade we still largely expect to recruit by promotion from the shop floor". This reads more like a lament from a charge-hand than an observation by a skilled industrial investigator. Does it need Lord Robbins, or the report of the Committee on Higher Education of which he was chairman, to persuade the author that the graduate recruit differs only from the secondary modern recruit in that his period of formal education lasts longer and that, until they start work, both must be considered as outsiders? Moreover, that, increasingly, supervisory jobs are being filled by graduates and their equivalents as part of their development on the way up?

T. H. HAWKINS

SHORT REVIEWS

Logic, Computing Machines, and Automation

By Alice Mary Hilton. Pp. xxi+427. (Washington, D.C.: Spartan Books; London: Cleaver-Hume Press, Ltd., 1963.) 72*s*.

MATHEMATICAL logic is an essential component in the basic theory of computors and automatic controllers. However, to-day these subjects are in their early stages and the most erudite specialist would find it impossible to write a book explaining adequately all the connexions between logic and these applications. It is, therefore, a very difficult undertaking to give some notion of these connexions to the general reader, which is what *Logic, Computing Machines, and Automation* sets out to do. The book is a succession of summaries of mathematical logic, some parts of mathematics, the operation and programming of computers, and a small section on automation. Parts of these summaries are quite good, but the real problem is to link them together so as to give the reader a coherent picture. Little attempt is made at this linking; for example, the reader has two pages in which to struggle with the ideas of material implication, conditional implication, and strict implication; if he succeeds in mastering them he then finds that they lead nowhere. A good exposition for the general reader remains to be written; when it comes it will be much less ambitious, and much more attuned to the way that people absorb difficult technical material.

J. J. FLORENTIN

Electrical Instruments and Measurements

By W. Alexander. Second edition. (Cleaver-Hume Electrical Series, No. 5.) Pp. 350. (London: Cleaver-Hume Press, Ltd., 1962.) 25*s*. net.

THIS book was first published in 1951 and has now been revised for the second edition. It is primarily intended for the use of technicians, and the small size of the pages makes it easy to carry about in one's pocket. The only obvious disadvantage of the small page size is that some of the detail of the diagrams and photographs is difficult to see clearly.

The book opens with a very readable chapter on fundamental principles and this is followed with simple descriptions of ammeters, voltmeters, wattmeters, power-factor meters, frequency meters, quantity meters and energy meters. The nature of the quantities measured is described with a minimum of mathematics and plentiful diagrams, and there are useful chapters on the testing of instruments and circuits. A few test questions and numerical answers are included. The material is generally well chosen, but the measurement of three-phase volt-amperes and power factor is inadequately covered and the possibility of obtaining widely different results according to the definition of volt-amperes does not appear to be mentioned.

Instrument transformers are discussed as a means of extending the range of voltage and current measurement, but the testing of these devices is not described. The only method of compensating errors given is "turns compensation" for ratio, and on p. 87 the author denies the existence of methods for compensating phase error, which is astonishing.

Apart from these minor blemishes the book is excellent and should prove very popular.

A. H. M. ARNOLD

Electronic Properties of Diamonds

By Prof. F. C. Champion. Pp. vii+132. (London: Butterworth and Co. (Publishers), Ltd., 1963.) 25*s*.

THIS scholarly small monograph on the present state of knowledge about the electronic properties of the diamond crystal is most welcome. There are two important research schools concerned with the electro-optical properties of diamonds, that of Prof. Ditchburn at Reading, and that of Prof. Champion himself at London, and as might be expected this account is authoritative. Diamond, despite it chemical simplicity, is a crystal which seems to exhibit an enormous range of physical structural complexities, and from the bewildering mass of published data the author has produced a readable summary which will be invaluable to all scientists (and there are many) engaged on the investigation of the physical properties of diamond.

The book is divided into two roughly equal parts. The first part consists of eight brief chapters which review a formidable amount of already reported experimental material concerning: (*a*) optical properties of theoretically perfect and of real diamonds, (*b*) electrical and photo-conductivity, (*c*) diamonds as scintillation and as conduction counters for radiations, (*d*) radiation damage to diamond; (*e*) semi-conducting diamonds, (*f*) electro-luminescence.

The second part is a novel contribution for a monograph of this size, since it is in effect an original attempt to explain a considerable number of the physical properties of diamond in terms of structural defects and energy-levels. Prof. Champion achieves a fair measure of success with his theory and accounts for numerous specific properties in some detail. Undoubtedly a stimulating section, much of which seems very sound to me.

A very useful brief monograph indeed.

S. TOLANSKY

The Application of Mathematical Statistics to Chemical Analysis

By V. V. Nalimov. Translated by Prasenjit Basu. Pp. ix+294. (Oxford, London, Paris and Frankfurt: Pergamon Press, 1963.) 84*s*.

THE title of this book will immediately catch the eye of any chemist seeking instruction in the use of statistics in his work. The newcomer to statistical methods will, however, find the book heavy going and would do well to obtain his primary background in the subject from some simpler English text-book. On the other hand, those chemists who already possess some knowledge of statistical methods will appreciate the value of a book applying statistics to their particular problems.

Our old friends, the Normal, Binomial and Poisson distributions, the '*t*' test and the χ^2 test, are all described with reference to chemical analysis. The analysis of variance is applied to the problem of variance between and within laboratories. The statistics of regression are applied to the standard graphs widely used in modern analysis and, in this connexion, the attention given to the correlation between the parameters of the regression equation is interesting as this correlation is not usually discussed in our elementary monographs. Another technique which may be fresh ground to some chemists is that of sequential analysis which is described here, oddly enough without reference to *Sequential Analysis* by Abraham Wald

There are various minor errors of either translation or printing which might confuse the uninstructed beginner, since the sense can only be recovered by a critical examination of the text A notable omission is that of the levels of significance from Table 6, pp 264–267

In discussing analysis of variance it is unfortunate that the author has chosen to describe what is clearly variation 'within columns' as variation 'between rows', a term which bears a quite different meaning in English text-books

I found the English somewhat stilted and prolix, but perhaps this is a common feature of translations Nevertheless, these various blemishes need not deter the prospective purchaser and the book will be an instructive addition to the chemist's bookshelf provided, as suggested here, it is not the only statistical text-book there

O F NEWMAN

Analytical Chemistry 1962

The Proceedings of the International Symposium held at Birmingham University (U K), April, 1962, in Honour of Fritz Feigl to Commemorate his 70th Birthday Edited by Philip W West, A M G MacDonald and T S West Pp x+411 (Amsterdam and London Elsevier Publishing Company, 1963) 90*s*

THIS book is a compilation of sixty-five lectures presented at the Feigl Symposium and the resulting discussions To fashion such a miscellany of papers on chemical analysis into book form, and at the same time preserve a certain continuity, presents difficulties, but the editors have surmounted these with considerable success.

After two introductory papers, including a biographical sketch of Dr Feigl, the first section of twelve papers deals with spot-testing and qualitative analysis It is in this section that most original work is reported on Three papers on semiquantitative spot-test methods and then fifteen papers on organic reagents and their applications to chemical analysis follow These latter groups of papers are mostly in the form of reviews

The second half of the book is devoted, apart from three miscellaneous papers at the end, to physico-chemical analysis comprising thirty contributions on electrochemical, radiochemical and optical methods, separation processes and titrimetric analysis Again, these papers are mainly reviews, most with a sizable and useful list of references One criticism of this section is possibly its lack of balance with six papers on polarographic techniques and four on atomic absorption This leads to a certain repetition especially within the contributions on the latter topic In contrast only one paper on gas chromatography appears

The book is well produced and remarkably free from typographical errors although C instead of c appears as the abbreviation for curie (pp. 23, 87 and 105) It can be recommended to analysts as providing an up-to-date account of most topics within the sphere of modern analytical chemistry

R WOOD

How Chemical Reactions Occur

An Introduction to Chemical Kinetics and Reaction Mechanisms By Edward L King (General Chemistry Monograph Series) Pp xi+148 (New York and Amsterdam W A Benjamin, Inc , 1963) 2 15 dollars paper-back, 4 35 dollars cloth back.

ABLE pupils in the sixth form, or students in their first year, will gain a great deal from *How Chemical Reactions Occur* It makes no attempt to introduce a large number of reactions, the few chosen are well known and are used to the full First the meaning of 'reaction mechanism' is established and attractive diagrams add to the clarity The rate laws are next introduced, and adequate space is given to defining the terms involved· rate, concentration and velocity constant Some methods of examining rates of reaction are given, and this subject is taken up again in a later chapter when very fast reactions are discussed The treatment of molecular collision frequency will appeal to many students, and the discussion of activation energy which follows is equally well done The remainder of the book is given to using the ideas so carefully introduced The reactions chosen serve ideally There are interesting chapters on catalysis and on the use of radioisotopes in the examination of mechanisms

Each chapter ends with a number of problems, some of them well worn, many quite novel There is an interesting glossary and a very detailed reading list Some of the books suggested demand a great deal more mathematical ability than the one under discussion requires Here is a book which will win its way into a great many personal libraries.

D C FIRTH

The Structure of Molecules

An Introduction to Molecular Spectroscopy By Gordon M Barrow (The General Chemistry Monograph Series) Pp xi+156 (New York and Amsterdam W. A Benjamin, Inc , 1963) 2 15 dollars paper back, 4 35 dollars cloth back

DR BARROW has written this account of molecular spectroscopy with a simplicity and clarity possible only from a born teacher, but since he is also one of the subject's chief practitioners, he makes no apologies for the difficulties involved in analysing spectra of all but the simplest molecules The monograph will be welcomed by first- and second-year students at universities and technical colleges

The book covers rotational, vibrational, vibrational-rotational and electronic spectra, and explains how bond-lengths, bond-angles and force constants can be determined to a high degree of accuracy The energy considerations of vibration and rotation are discussed in classical terms and the quantum limitations are imposed without recourse to the Schrodinger equation Sixth-form mathematics is all that is required from the student General practical details are given and each chapter gives an account of the possibilities of future research Each chapter begins with a survey of the material to be presented and concludes with a summary and with numerical calculations from the text

The introductory chapter deals with the nature of radiation the ways energy can be stored within a molecule and how the quantum laws are applied The final chapter on the electronically excited states of molecules will prompt the student to ask questions about the properties manifested by these entities

Dr Barrow retains a humility before his subject, and one marvels at "the way one is led very directly into the world of molecular dimensions", and how much of the geometry and movement within a molecule can be deduced from spectra

D M RUSSELL

Chemical Thermodynamics

By Prof J A V Butler Fifth edition Pp xvii+601 (London Macmillan and Co , Ltd ; New York· St Martin's Press, Inc , 1962) 25*s* net.

PROF BUTLER'S *Chemical Thermodynamics* requires little introduction It is a tribute to its popularity (perhaps more with university teachers than with their students) that the book has retained its position for so long and that its thirty-fifth anniversary should be celebrated with a fifth edition The bulk of the book remains largely unaltered, and the author is unashamed that up-to-date values have not been substituted for some thermochemical quantities because the original data well suit the author's purpose of illustrating his arguments and principles. This reflects the function of the book—

it is a text-book, and its role is to give the student the thermodynamic background required by a degree course and to be an introduction to more advanced treatises Part 1 covers the first two laws of thermodynamics, dilute solutions and electrochemistry, Part 2, with entropy, free energy, the third law, solutions and thermodynamic functions, is designed to be studied as a second course

There are two new chapters. One is an introduction to the thermodynamics of irreversible processes (such as transport across membranes), and the other (by Dr D. J R Laurence) is on the thermodynamics of polymers, and discusses the extensions necessary to account for the properties of polymer solutions, in which entropy considerations are naturally dominant, and the consequences which occur when solvent and solute are of a different order of molecular magnitude D M Russell

Pyridine and its Derivatives

Part 3 Edited by Erwin Klingsberg (The Chemistry of Heterocyclic Compounds a Series of Monographs, Vol 14, Part 3) Pp ix+914 (New York and London Interscience Publishers, a Division of John Wiley and Sons, 1962) 488*s*

THIS, the third and largest, part follows the format of the previous two and comprises four chapters on some functional derivatives of pyridine

A S Tomcufcik and L N Starker contribute to the first chapter (177 pp) on aminopyridines References to infra-red studies relating to the structure of these compounds are quoted up to 1952 Perhaps some note might have been included here to the later contributions made by Katritzky *et al*

The next two chapters are devoted to carboxylic acids The first is by E P Oliveto and includes an excellent account of their preparation reactions and functional derivatives The chapter concludes with a short account of some aspects of the naturally occurring derivatives of this group in vitamins and alkaloids The second chapter on acids, by J C Godfrey, is concerned with the carboxylate group as a side-chain in the pyridine nucleus The subject material is given the same systematic treatment as before

Pyridinols and pyridones, which are important intermediates in the armamentarium of the synthetic organic chemist, are adequately dealt with in the last chapter (382 pp) by H Meislich The aforementioned chapters are remarkably free from errors and each is well supplemented with tables and a comprehensive bibliography This is a most useful contribution to the chemistry of pyridine and maintains the high standard of the series

The high cost precludes its purchase by the vocational organic chemist, and any browsing involves the borrowing for the night or week-end from the works or academic reference library R Hull

Spectrometric Identification of Organic Compounds

By Dr Robert M Silverstein and Dr G Clayton Bassler Pp viii+177 (New York and London John Wiley and Sons, Inc , 1963) 64*s*

THIS is in many ways an unusual, but welcome, scientific publication The strongly didactic character of its presentation will appeal particularly to advanced students who are anxious to improve their knowledge of modern instrumental techniques and of their diverse applications

The book is of quarto size, the text printed legibly on good paper, and the tables and diagrammatic illustrations are all that one could reasonably expect Four earlier chapters are individually devoted to the fairly detailed study of each of four spectrometric methods The older, rugged techniques of infra-red and ultra-violet spectrometry are considered side-by-side with the more complex modern instrumental systems concerned with nuclear magnetic resonance and fragment mass spectroscopy The finer details of instrument design are left to more authoritative text-books, but sufficient information is given to provide the tyro with a clear picture of the functioning of a particular instrument and of the theoretical implications of the recorded data which it provides

In later chapters, the authors illustrate the powerful part which these techniques can play in the unequivocal identification of small (but pure) amounts of various organic compounds Tetramerous analytical exercises have been carried out with these instruments on various organic substances All the experimental data are clearly presented, the physical clues are marshalled and critically examined Conclusions are then drawn with a Holmesian precision and provide a composite molecular and structural diagnosis which could well excite the admiration of sterner and less-gullible observers than the susceptible Dr Watson Quantities of less than one milligram of unknown substance are adequate for all techniques with the exception of nuclear magnetic resonance, and only in the special instance of fragment mass spectroscopy does the original sample under examination become irrecoverable

Tables of numerical data are given which greatly simplify the interpretation of the many quatern spectra which the authors have provided for twenty organic compounds of various types Thus 26 pages are devoted to J. H Benyon's tables for the masses and isotopic abundance ratios for various combinations of carbon, hydrogen, oxygen and nitrogen, that is, values of the 100 per cent parent peak "P" and of $(P + 1)$ and $(P + 2)$ Similarly useful tabular data are provided for the other spectrometric disciplines described in this work The final chapter provides 10 sets of quatern spectra with Beilstein references, a most useful complementary student exercise

This book is reasonably priced and is certain to attract the attention of those who wish to revise their knowledge of the older techniques and to keep abreast of the surging tide of modern physical science D T Lewis

Les Cyclitols

Chimie, Biochimie, Biologie Par Prof Théodore Posternak (Chimie des Substances Naturelles) Pp 492 (Paris Hermann, 1962) 48 N F

THIS volume, one of the admirable series on the chemistry of natural products, deals with the monocyclic polyhydric alcohols in general, but its main concern is with the inositols and derived substances These are, of course, the most important of the natural cyclitols and constitute a large group of compounds which, however, are chemically relatively simple These range from the unsubstituted hexahydroxy*cyclo*hexanes through methylated derivatives to the complex lipids, the phosphoinositides *Meso*(myo)-inositol is a growth factor for many organisms including mammals, although its status as a vitamin, in man, is disputed

Prof. Posternak has devoted much of his research career to the chemistry and biochemistry of these compounds, and has now, fittingly, produced this scholarly work in which every aspect of the subject is discussed in a detailed but readable fashion The book is timely, because much of the chemistry is now well understood as a result of work in the intervening years since the previous major work in this field was published some fifteen years ago On the contrary, however, the biological involvement of these substances is not at all clear and one may expect that the book will give added stimulus to further work

This soft-covered, but sturdy, volume is beautifully produced References include those to work published in 1960 but a number of pages of addenda at the end of the book discuss more recent work It should find its way on to the shelves of all chemical and biochemical libraries D M Brown

Biological Receptor Mechanisms

Edited by J W L Beament (Symposia of the Society for Experimental Biology, No 16) Pp vi+372 (Cambridge At the University Press, 1962 Published for the Company of Biologists on behalf of the Society for Experimental Biology) 50s net

THIS volume can be recommended to all interested in the physiology of sense organs it is well produced and represents excellent value The editor defines biological receptor mechanisms as "mechanisms whereby living organisms transform or transduce the information in their environment" About one-quarter of the book is devoted to botanical problems.

Five articles concern aspects of the physiology of vision, with emphasis on the primary process of light-energy capture in vertebrates and on the optical characteristics of the arthropod compound eye An account of the dislocation theory of smell is followed by a survey of recent work on the chemoreceptive hair of insects The evidence for an electric sense in fish is reviewed Further contributions deal with animal temperature receptors, the ear, the labyrinth, and the electrophysiology of single mammalian mechano-receptors The problem of coding in primary receptor neurones is then discussed

The four botanical contributions are restricted to photosynthesis, non-photosynthetic effects of light on higher plants and on fungi, and 'gravi-perception'

This symposium is a valuable summary of progress made in the past decade The contributions are well illustrated and well documented, and achieve a uniformly high standard Unfortunately, since the zoological material is confined to vertebrates and arthropods, it is left to the imagination of the reader to establish a connexion between the botanical articles and the rest of the book Some animal physiologists may feel that the word 'perception' is abused by the botanists, and that photosynthesis is scarcely a receptor mechanism

D H SPROULL

Infectious Diseases of the Honey-Bee

By Dr Leslie Bailey Pp 176 (London Land Books Limited, 1963) 25s

THIS is the first book in English to be devoted entirely to diseases of the honey-bee, and it is both very comprehensive and interesting The first part deals with the biology of pathogens found in honey-bee colonies followed by the pathology, epidemiology and world distribution of the diseases they cause, in the second part, techniques of diagnosis and control are covered in detail There is also a chapter on non-infectious diseases and diseases of unknown origin

The author's style is for the most part clear and concise, and the photographs and diagrams illustrate the text very satisfactorily The seven graphs and histograms (all recording experiments by the author) are, however, not all presented in a form which can be immediately understood, and this is unfortunate in a book which is intended not only for scientists but also for beekeepers with some biological knowledge Certain other minor criticisms can be made of this otherwise very successful book For example, there are two contradictory statements about the harmfulness to bees of Frow's mixture for acarine disease (p 117), and the control of *Braula coeca* receives only one short sentence despite its relatively widespread occurrence On a few occasions, general statements are made about normal colony development without supporting evidence being provided, but these omissions are outweighed by the 390 references to original work on diseases quoted unobtrusively in the text and listed at the end

Dr Bailey has undoubtedly taken the right course in using his specialist knowledge to produce a book primarily for biologists, and it is to his credit that it will also be welcomed by beekeepers with an active interest in science

M DELIA ALLEN

The Compound Eye of Lepidoptera

Approach from Organic Evolution By Prof. N. Yagi and Prof N Koyama Pp 319. (Tokyo, Japan Maruzen and Co, Ltd, 1963) n p.

THIS is a very complete and fully illustrated account of the morphology of the compound eyes of the Lepidoptera, considered especially from the point of view of the evolution of the group

All features of the eye, both external and internal, are described in considerable detail and are illustrated by many diagrams and photographs The structures are then described in each of thirty-seven families representing most types of the order but rather heavily weighted on the side of butterflies and the larger moths For each group a phylogenetic diagram is constructed which shows relationships so far as these can be deduced from eye-structure alone It is perhaps misleading to refer to phylogenetic relationship when such a narrow range of structure is considered, but it is easy to extract the facts from the speculation The present account is much the fullest one available of the structure of the eyes of Lepidoptera.

Final sections deal with rhythmic migrations of retinular pigment and with the theory of image-formation in the compound eye The authors reach the same conclusion as Burtt and Catton did in 1962, that a number of separate images in numerous ommatidia are integrated and that image-formation does not depend on a pattern formed of lighter and darker dots, each dot corresponding to an ommatidium The volume constitutes an important contribution to our knowledge of the compound eye and of the morphology of the Lepidoptera

O W RICHARDS

California Desert Wildflowers

By Philip A Munz Pp 122 (96 plates) (Berkeley and Los Angeles · University of California Press, London : Cambridge University Press, 1962) 2 95 dollars, 24s

California Mountain Wildflowers

By Philip A Munz Pp 122 (96 plates) (Berkeley and Los Angeles University of California Press, London Cambridge University Press, 1963) -2 95 dollars, 24s

Early Uses of California Plants

By Edward K Balls (California Natural History Guides 10) Pp 103+8 plates (Berkeley and Los Angeles University of California Press, London Cambridge University Press, 1962) 1 75 dollars, 14s

CALIFORNIA Desert Wildflowers and *California Mountain Wildflowers* complete the author's attractively produced, non-technical, three-volume series which can be "placed in the glove box of the car or easily carried on a hike" The two slim volumes are identical in format and include an introductory section concerning the habitat and identification The majority of the species then dealt with are illustrated by clear line drawings and divided into groups according to flower colour Here, and in the comprehensive colour section also, the pages are divided into two columns, illustrations in the outer, and text, giving the common and botanical names, diagnostic features, habitat and distribution of each species, in the inner The selection of species has been well planned to avoid overlap between the volumes, to figure the interesting though not necessarily showy or common, and, in the case of complex groups of species, to illustrate one as an example and mention others closely similar Indexes are provided Together with their companion volume *California Spring Wildflowers* these guides are admirable for their purpose and should be of especial interest to the intending visitor to California who has a love of wild-flowers

Early Uses of California Plants is the tenth in a series of pocket-sized guides "for the student, traveler or sportsman who wants to know more about outdoor California"

About a hundred species are dealt with according to their chief use and grouped as 'food plants', 'drink plants', etc Many are illustrated by line drawings (without scale) and by eight pages of coloured and half-tone photographs of varying quality The booklet ends with an article on present-day uses, a bibliography, and an index of vernacular names A handy little volume for the tourist with an interest in ethnobotany D R HUNT

Selected Botanical Papers

Edited by Prof Irving William Knobloch Pp xiv+311 (Englewood Cliffs, N J., and London Prentice-Hall Inc, 1963) 32*s*

PAPERS mostly of a rather general and philosophical kind, selected to illustrate the purpose and methods of a number of different branches of botanical science, make up this botanical digest for first-year university students Emphasis is American and modern, but not exclusively so; Humboldt, Nehemiah Grew, Fabricius and Aristotle accompanying Merrill, Blakeslee, Erdtman and Went. As they appear in their 'digested' state, the papers are incomplete and I wish that more had been given of some of them instead of the irritatingly naive little catechisms at the end of each

The idea behind this book—that the first-year university course is too often no more than a background for subsequent more advanced courses, irrespective of whether the students will proceed to the latter, and that the first course should, therefore, be more broadly and more philosophically based—is a good one The editor's confidence in the assertion in his preface, that large proportions of first-year students (82 per cent is quoted for botanists) in certain universities in the United States "*never* go further" in their subjects, seems questionable if it is based purely on academic records It is possible to keep a worth-while interest in a subject without proceeding to advanced university courses in it J P M BRENAN

Symposium on the Impact of Man on Humid Tropics Vegetation

Goroka, Territory of Papua and New Guinea, September 1960 Sponsored by the Administration of the Territory of Papua and New Guinea and the Unesco Science Co-operation Office for South East Asia Pp 402 (Canberra A J Arthur, Commonwealth Government Printer, 1963)

THIS publication of the proceedings of the Goroka symposium (see *Nature*, 189, 24, 1961) should interest biologists, educationists and administrators throughout the tropics It deals with the effect of untutored man on his environment About forty papers are grouped under the seven headings of the physical and human background of the Far Eastern humid tropics, wild food, the effects of fire, of grazing, and of shifting cultivation, the secondary vegetation thus produced, and the consequences of these activities on land-management, human plight, and scenery

Many of the papers are illustrated with maps and half-tone plates, and each chapter ends with the verbatim discussion which took place at Goroka The scope is vast, the issues are various, and nowhere is there a clear picture of causation, because the few investigators in this enormous region from Thailand to New Caledonia are still obliged to study by observation and inference

The sponsors are to be congratulated for this permanent record of pioneer conclusions, which J S Womersley has ably edited I hope that the publication, which is the third on the humid tropics from the Unesco Science Co-operation Office in Indonesia, will influence Unesco not to overlook the clear-cut issue of the humid tropics in the re-arrangement of its overseas programme The humid tropics stand for a biological richness which man, as yet, can only deplete E J H CORNER

Pathogenic Organisms in Relation to Pasteurized Cured Meats

By J I Anderton (Scientific and Technical Surveys, No 40) Pp 158 (Leatherhead The British Food Manufacturing Industries Research Association, 1963) 40*s*

HAM is a product which has been produced for centuries past Relatively large-scale production, different methods of marketing and retailing and the apparent demand by (or gradual conditioning of?) the 'average consumer' for less heavily cured products have all played their part in bringing about various changes over the years In turn, the use of weaker brines, lower processing temperatures and the retailer's keenness to display the sliced product (with no guarantee that refrigerated storage conditions will be maintained until time of consumption) have been matters of concern to microbiologists in particular in recent years In *Pathogenic Organisms in Relation to Pasteurized Cured Meats*, Anderton has critically reviewed the published literature relating to this potential hazard

The first main section is entitled "Possible Sources of Contamination" and each of the main types of spoilage organism is discussed Anderton then proceeds to survey each of the main processes involved, such as the effects produced during curing, smoking, boning, trimming, heat processing and storage Other sections relate to the detection of food-poisoning organisms, bacteriological standards for canned hams and the effect of antibiotics Most microbiologists will be aware that contamination is liable to occur at virtually any stage in the manufacturing process This booklet will nevertheless be of considerable interest to them and should assist those of their number employed in industry, who may find it necessary to advise or warn processing staff who wish to make further changes in the manufacturing procedure In fact this survey amounts to a warning for the future rather than a post-mortem after the damage has been done Further, the attention directed to the gaps in the literature should be most useful to research workers in this field

Two pounds may seem to some a high price for a booklet with a thin cover When one considers, however, that the list of references at the end covers some seven pages it will be readily realized that its production represents a comprehensive survey of the literature of a 'delicate' subject D PEARSON

Brompton Hospital Reports

Vol 31, 1962 (A Collection of Papers by Members of the Staffs of the Hospitals for Diseases of the Chest (Brompton Hospital and London Chest Hospital) and of the Institute of Diseases of the Chest) Pp xii+292 (London Lloyd-Luke (Medical Books), Ltd, 1963) 15*s* net

VOLUME 31 of the *Brompton Hospital Reports* is again noteworthy for the collection of articles dealing with various aspects of the diagnosis and treatment of diseases of the chest as well as a number of studies concerned with the embryology, histology and anatomy of the respiratory tract The volume also contains an article by Dr H R Barrett which was delivered as an address to the American Association for Thoracic Surgery at St Louis, Missouri, in April 1962 It is concerned with the publication of scientific journals and shows that responsibility for the production of responsible publications rests as much with the readers as with the editors and publishers Much wise advice is given to would-be authors, while all editors will respect the propriety of the rejection slip sent to a young graduate by a Chinese mandarin It read "We have read your manuscript with boundless delight If we were to publish your paper it would be impossible for us to publish any work of lower standard and, as it is unthinkable that, within the next thousand years, we shall see its equal, we are, to our great regret, compelled to return your divine composition, and to beg you a thousand times to overlook our short sight and timidity" T H HAWKINS

The Solar Corona

Proceedings of International Astronomical Union Symposium No. 16, held at Cloudcroft, New Mexico, U.S.A., 28–30 August, 1961. Edited by John W. Evans. Pp. xi+344. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.) 100s.

THE thirty papers presented at the Cloudcroft symposium, and contained in this volume, provide a comprehensive review of the considerable amount of research on the solar corona which is at present being undertaken. Contributions have been grouped in three sections—"Local Physics of the Corona", "Coronal Phenomena", and "Larger Aspects of the Corona"—each of which is introduced by one or two review articles.

The first section, with the introductory paper by C. W. Allen, discusses such topics as the discrepancy in the coronal temperatures obtained by different methods, the ionization and excitation equilibria and coronal line emission, and possible heating mechanisms. Mention should be made of a paper on "Solar X-Ray Emission" by H. Friedman which gives a survey of some impressive results in this wave-length region, obtained from rocket and satellite work. The second section has two reviews, the fast and the slow phenomena being discussed by J. P. Wild and by M. Waldmeier respectively. The flare-associated phenomena and the relationship of the corona to prominences receive much attention. There are also two or three interesting papers on observational techniques which might have been better grouped under a separate heading.

The section on the "Larger Aspects of the Corona" deals with questions of general structure, and with the origin and nature of corpuscular streams. This is probably the aspect of the subject which is most speculative at present, but which is most likely to benefit in the next few years from rocket observations in interplanetary space. The review for this section was written by S. Chapman, while E. R. Mustel made a substantial contribution on the corpuscular streams and their relationship to regions of solar activity. The volume also contains short reports of nine informal discussions, which are useful in pin-pointing those problems most in need of attention. A further section contains five communicated papers which could not be presented at the symposium for want of time.

During recent years, the study of the solar corona appears to have entered a new phase, with new observational techniques providing a wealth of information from the X-ray region to the radio wave-lengths. These *Proceedings* provide ample evidence of the rapid increase which is occurring in our understanding of the corona as a consequence. D. J. FAULKNER

An Economic Geography of Oil

By Dr. Peter R. Odell. (Bell's Advanced Economic Geographies.) Pp. xii+219. (London: G. Bell and Sons, Ltd., 1963.) 22s. 6d. net.

AVAILABLE literature of the petroleum industry contains more than average references to essential economics. They are chiefly statistical, as they would necessarily be, and as such find a relatively limited appeal in the broader sense of the technology. The trouble with these books and essays is that they tend to date in a matter of a few years after publication because, in the oil world particularly, economic circumstances change so rapidly that the mathematics of supply, demand, refining, transport and distribution throughout the world can never be reduced to static formulæ. This book, however, is in a rather different category in that the stress is on basic geographical analysis of the activities of the world oil industry, not so much on purely present-day statistical data and hypothetical trends in the future. Coming from the pen of a lecturer in geography at the London School of Economics and Political Science, it would be anticipated that the discipline of geographical science applied to the primary commercial factors in the industry would break new and profitable ground. Although the book is designated as an introductory investigation, partly owing to limitations on space, also because of what the author modestly describes as "... my own inability to grasp and to bring out all the relevant factors which contribute to the geographical distribution of the production, refining and consumption of oil", there is little doubt that a more ambitious treatise on the subject would, at this juncture, probably have defeated its object.

The book is divided into four parts—(1) the pattern of world oil supply, (2) the pattern of world oil demand, (3) refining, transport and distribution, (4) conclusion—concerned with the oil industry and economic development. Part 1 embraces consideration of the industry's resources, the world pattern of production and the determining factors thereof. Part 2 discusses the pattern of oil consumption and the factors influencing this demand. Part 3 describes the pattern of refining and the determinants of refinery location, also transport and distribution. Part 4 is in itself quite a masterly exposition of the relationship of the industry to the countries within which its activities are at present located. Here the author quotes R. C. Estall and R. O. Buchanan: "Oil does not in general attract major industries to its source of origin ... major industrial concentrations are not a normal feature of oilfields as they have been of coalfields". The author accepts this point as valid both in the past and to-day, and he advances good reasons why this should be so.

The book is well written, and not overwhelmed with masses of statistics although well supported with outline maps, tables and diagrams. As an attempt to bring an extremely complex and ramified subject into assimilable proportions, it deserves praise. H. B. MILNER

Spirit and Man

An Essay on Being and Value. By Prof. Nathan Rotenstreich. Pp. 257. (The Hague: Martinus Nijhoff, 1963.) 20.75 guilders.

SPIRIT and Man is essentially a study in ethics. The outlook is contemporary, but with a well-balanced historical background. Novelty is scarcely to be expected, but the author makes several interesting observations. Examples are the limitations of calculating machines, the risk of obliterating creativeness and responsibility if systems of Government are too 'paternal', and the dilemma of true freedom in terms of detachment from man's immediate environment. Evidently, some of these questions are of importance to scientists, especially problems relating to team-work in research, and the delicate balance between policies dictated from outside, and the desire of the individual (sometimes) to follow his own inclinations.

The book is divided into three main parts: (1) dimensions, (2) features and (3) significance. In addition, there is an adequate index.

Naturally, the reader will expect a decidedly axiological slant, and in this he will not be disappointed. In fact, the writer sums up by declaring his purpose to be to establish man's worthiness as anchored in the fact that he is a subject, and that the value of his being so is not arbitrary, either anthropocentrically or otherwise.

The text, however, is marred by an excessive number of printer's errors (singulars for plurals, misplaced punctuation, careless spelling, and so forth). The proof-reading must have been much below the standard usually achieved by the publishers. In addition, the writer has the tiresome habit of using the phrase "to be sure" far too often, sometimes even twice on the same page. Nevertheless, it is a useful book in itself, and worth careful study.

nating between the PGE and PGF types. The main active constituent of Q was concentrated by this means into fractions 10–17 (concentrate S; 20 mg) of a 60-component fractionation (Fig. 4) and chromatographically resembled a PGF. Successive further fractionation with change in pH finally produced an acidic concentrate U ($\sim 0{\cdot}5$ mg) showing intense PGF-type activity corresponding to an equivalent content of 2 mg of PGF$_{1\alpha}$. A similar process applied to concentrate R led to concentrate V ($\sim 0{\cdot}5$ mg) with pronounced PGE-type activity, corresponding to an equivalent content of 0·2 mg of PGE$_1$.

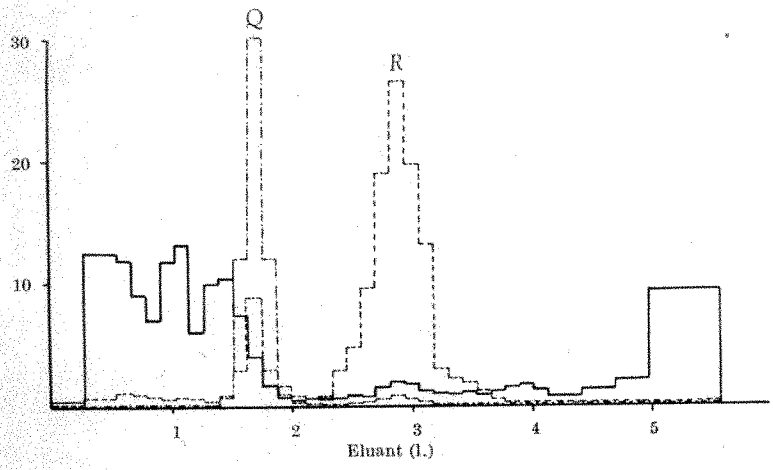

Fig. 2. Reversed-phase partition chromatography of concentrate P. Stationary phase: 70 ml. iso-octanol/chloroform (1 : 1) on 100 g of hydrophobic 'Embacel'. Moving phase: 47·5 per cent aqueous methanol. —— Weight distribution; abscissa units 1 mg/ml.; -·-·- bioassay on rabbit jejunum; abscissa units 6 μg PGF$_{1\alpha}$ equiv./ml.; - - - - bioassay on guinea pig uterus; abscissa units 15 ng PGE$_1$ equiv./ml.

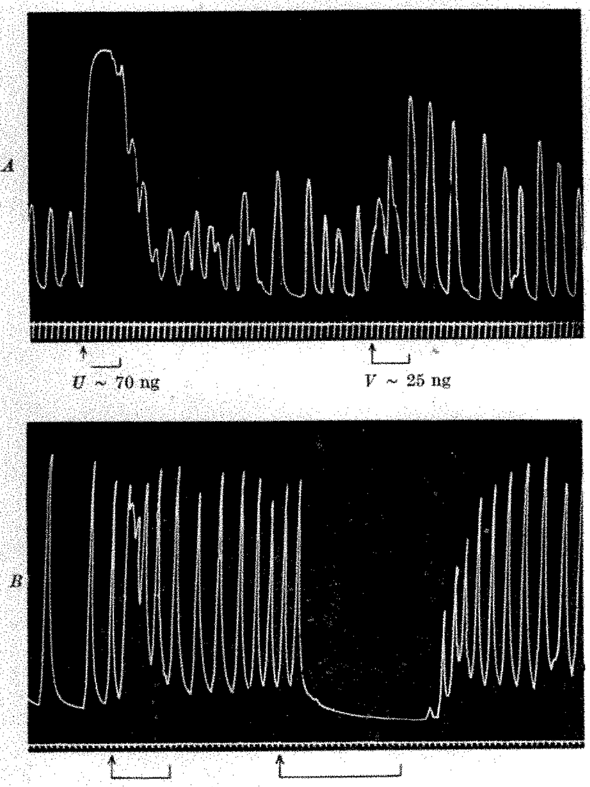

Fig. 3. Effects of menstrual stimulants on human myometrial preparation *in vitro* (bath-volume 4 ml.; time marker, 1 min). A, preparation showing good positive responses; B, preparation showing well-marked inhibitory responses to concentrate V

The next step involved the precise identification of the actual active principles in concentrates U and V. So far the tentative correlation with the two prostaglandin types had rested on the close parallel between the chromatographic behaviour and the type of biological activity. A routine chemical identification by preparation of derivatives was obviously impossible in view of the minute amounts of the concentrates U and V available. Accordingly, thin-layer chromatography comparisons were made between the concentrates U and V and authentic samples of PGE$_1$, PGF$_{1\alpha}$ and PGF$_{1\beta}$ kindly supplied by Prof. Bergström.

Concentrate U showed a single major spot by thin-layer chromatography which was readily detectable by the characteristic red-brown fluorescence in ultra-violet light which developed after its exposure to acid ceric sulphate, followed by moderate heat; this spot contained the physiologically active substance. Both PGF$_{1\alpha}$ and PGF$_{1\beta}$ gave this colour reaction and the former gave a thin-layer chromatography spot close to that given by this menstrual stimulant of concentrate U (Fig. 5a).

Treatment of concentrate U with diazomethane gave a relatively inactive product which most significantly showed the characteristic spot (thin-layer chromatography) at a slightly greater R_F value than that of authentic PGF$_{1\alpha}$ methyl ester (Fig. 5b). Location of this spot by an iodine spray[11] facilitated extraction of the active substance without damage. This product was then exhaustively methylated with diazomethane–boron trifluoride and examined by thin-layer chromatography. The major discrete spot behaved chromatographically in a manner exactly analogous to that shown by PGF$_{1\alpha}$ trimethyl ether methyl ester using the hexane–ether system.

At this stage, both the sample and comparison spots of the completely methylated products were extracted, after location by the iodine technique, and the minute amounts of product (~ 50 μg) examined separately by gas liquid chromatography. As may be seen (Fig. 6), the product derived from concentrate U and that derived from PGF$_{1\alpha}$ behaved very similarly, although not identically. By comparison of the relative retention volumes with those for standard fatty acids on this non-polar column the observed difference strongly suggested that the menstrual stimulant present in concentrate U was in fact PGF$_{2\alpha}$ which contains one more double bond than PGF$_{1\alpha}$ in the carboxylated side-chain.

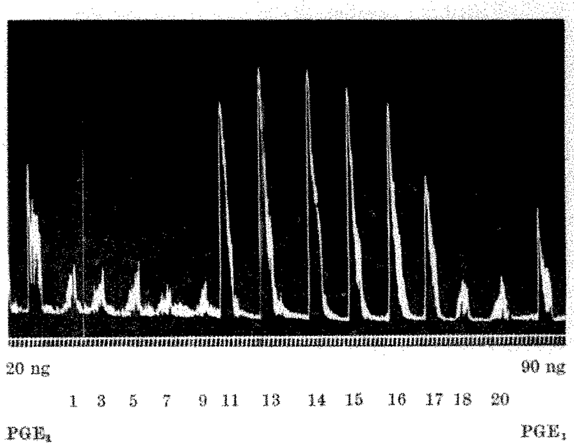

Fig. 4. Rabbit jejunum responses (bath-volume 4 ml.; time marker 1 min) to 1/1,000th aliquot of fractions 1–20 of reversed-phase chromatogram of concentrate Q showing PGF-type in fractions 11–17 (concentrate S)

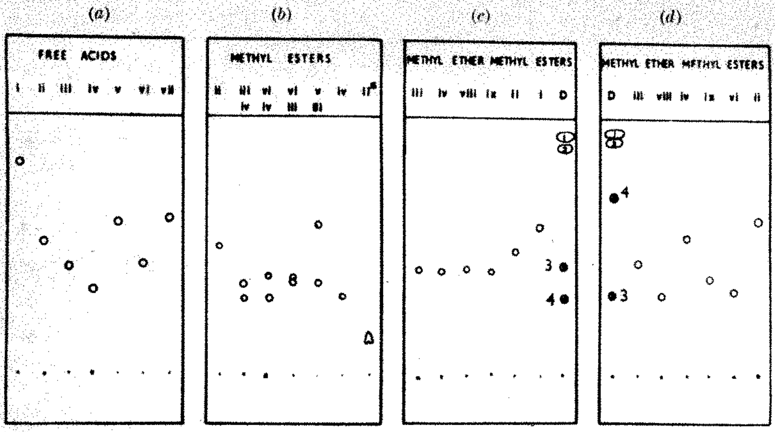

Fig. 5. Characteristic thin layer chromatograms on 0·2 mm layers of 'Kieselgel *G*' of prostaglandins and allied compounds. *a*, Chloroform/methanol/water, 60 : 10 : 0·5 v/v. Layers made up with 0·2 N oxalic acid pre-washed with developing solvent and developed in saturated atmosphere. *b*, As in (*a*) except that layers were made up normally and not pre-washed. Note tailing of phloionolic acid (ii*); *c*, Hexane/ether, 1 : 1; saturated atmosphere development. *d*, AnalaR chloroform in non-saturated atmosphere. Substances: (i) 15-hydroxypentadecanoic acid; (ii) 9,10,18-trihydroxyoctadecanoic (phloionolic acid); (iii) $PGF_{1\alpha}$; (iv) $PGF_{1\beta}$; (v) PGE_1; (vi) concentrate *U*; (vii) concentrate *V*; (viii) least polar borohydride reduction product from concentrate *V*; (ix) most polar borohydride reduction product from concentrate *V*. *D*, Dye marker mixture of (1) azobenzene, (2) sudan red, (3) *p*-hydroxyazobenzene, (4) *p*-aminoazobenzene

This was substantiated by the thin-layer chromatography behaviour of the trimethyl ether methyl ester derivatives of $PGF_{1\alpha}$ and of the menstrual stimulant using silver nitrate complex formation on the plates[12]. The relative change in R_F value on formation of the complex indicated that the menstrual stimulant contained an additional double bond as compared with $PGF_{1\alpha}$ and that this double bond was probably of the *cis* configuration.

Final confirmation of this identity with $PGF_{2\alpha}$ was obtained by mass spectrometric comparison of the trimethyl ether methyl ester derivatives of $PGF_{1\alpha}$ and of the menstrual stimulant.

As only small quantities of each compound were available (~ 10 μg), a special technique was utilized by which the compounds were introduced directly into the ion source. The spectra were obtained by an A.E.I. *M.S.*9 double-focusing mass spectrometer and were run and analysed by Dr. M. Barber and Dr. M. Elliott of A.E.I., Ltd., Manchester, and Dr. R. I. Reed of this Department, who report as follows.

"The spectrum of $PGF_{1\alpha}$ trimethyl ether methyl ester has already been reported[13] and our spectrum agreed closely (Fig. 7*B*). One interesting difference observed by us was the parent molecular ion M/e = 412 which was not previously reported.

"The spectrum of the concentrate *U* derivative was very similar (Fig. 7*A*). Up to M/e = 179 the two spectra are the same whereas above M/e = 249 the corresponding ions have a mass two units smaller in the menstrual derivative. The two compounds are therefore of similar structure, but the concentrate *U* derivative contains one more double bond. The cracking pattern is entirely consistent with the assignment of the structure $PGF_{2\alpha}$ trimethyl ether methyl ester to this concentrate *U* derivative."

Concentrate *V* was similarly examined by thin layer chromatography (Fig. 5*a*) and showed, after destructive spraying and heating, a pale-blue spot under ultra-violet light (a characteristic of the PGE family) at a position closely similar to that simultaneously obtained for an authentic sample of PGE_1; the activity of this spot was also shown to be of the PGE type.

Sodium borohydride reduction of an aliquot of *V* (equivalent to 6 μg PGE_1) and examination of the products by thin-layer chromatography revealed that the pale blue spot moving in the PGE region had been converted into two spots closely comparable in R_F value and colour to $PGF_{1\alpha}$ and $PGF_{1\beta}$. This chromatographic change was paralleled by the corresponding change in the type of physiological activity which was now only present in the PGF region of the plate.

The remainder of the concentrate *V* was similarly reduced and the PGF-type products purified using Bergström's second system. After conversion to the trimethyl ether methyl ester derivatives the two isomers were resolved by thin-layer chromatography on 'Kieselgel *G*' plates by means of chloroform (Fig. 5). In this system the $PGF_{2\beta}$ derivative migrates faster than the corresponding $PGF_{2\alpha}$ compound and, although the conditions are difficult to control, rather remarkable separations are possible. Final purification of each trimethyl ether methyl ester using the more consistent, but less selective, hexane ether system was followed by gas liquid chromatograph analysis of the products. One of the isomers was found to be identical with that obtained from concentrate *U* (that is, $GPF_{2\alpha}$) and the other possessed an R_F value in accordance with that predicted for $PGF_{2\beta}$. Thus the identity of the menstrual stimulant in concentrate *V* was confirmed as PGE_2.

The known occurrence of prostaglandins in human semen[9] made it highly desirable to exclude the possibility that this might be the source of the prostaglandins in our menstrual fluid samples. Accordingly, a number of specimens were examined which were known to be free from this possible adulteration, and which had been collected in menstrual cups in order to avoid any contamination from the usual absorbent materials. They showed physiological, chromatographic and chemical behaviour identical with those exhibited by the main collection.

The identification procedures described in this article were carried out on amounts of material ranging from

1 to 50 μg and demonstrate convincingly the power of modern separation and spectroscopic techniques when allied to physiological potency of such a high order.

The isolation of these two prostaglandins from human menstrual fluid adds this source to the several already described[9] for this class of compound. From our present results we cannot estimate their concentration in the secretory endometrium; but the yield of $PGF_{2\alpha}$ from menstrual fluid is comparable with that obtained by Bergström *et al.* from pig lung[14]. The quantity of PGE_2 is, however, much less than that of the PGE substances in human semen[9]. The 'menstrual stimulant' prostaglandins in the female may be thought of as homologous to the seminal prostaglandins in the male; however, the wide distribution of smaller amounts of these highly potent substances suggests that they may have some general type of action. For example, Vogt[15] has suggested that the smooth-muscle contracting long-chain hydroxy-acids may interact with calcium ions, and Clegg, Hopkinson and Pickles[16] have independently suggested a somewhat similar interaction with magnesium ions.

This work was carried out under the auspices of the Medical Research Council and the National Research laevelopment Corporation. We acknowledge with particuDr gratitude the generous provision of reference samples by Prof. Sune Bergström.

ANOMALY OF ALDOLASE IN PRIMARY LIVER CANCER

By FANNY SCHAPIRA, JEAN-CLAUDE DREYFUS and GEORGES SCHAPIRA
Laboratoire de Recherches de Biochimie Médicale, Hôpital des Enfants-Malades, Paris

RESEARCH in enzymology has been more extensive in experimental cancer than in human cancer, quantitative investigations not always being valid in post-mortem cases and biopsies not always being possible.

The discovery of multiple molecular forms of the enzymes named by Markert and Moller "isozymes"[1] enabled us to re-orient this research on a new basis. In the animal, Angeletti and Moore[2,3] have shown three peaks for glucose-6-phosphate dehydrogenase of mouse rhabdomyosarcoma, by chromatography on substituted celluloses, instead of one peak in the normal muscle; they have obtained analogous results on the acid phosphatase of the rat hepatoma, in which the chromatographic pattern is different from that of normal liver.

In man, Starkweather and Schoch[4], removing cancers of diverse origins a few hours after death, found that the distribution of the five isozymes of lactic-dehydrogenase, very varied in normal tissue, tended to become uniform and to predominate in one peak in cancer tissue.

The mode of action on the two substrates, fructose-1,6-diphosphate and fructose-1-phosphate, of aldolase from different tissues, and more particularly of hepatic aldolase, has given us a new approach for the enzymological examination of hepatomas.

One of us, with Payet[5], had, in 1960, pointed out that hyperaldolasæmia in the course of a primary liver cancer was not of the hepatic type, in the sense that the ratio of the two aldolase activities, fructose-1,6-diphosphoaldolase and fructose-1-phosphoaldolase $\left(\frac{\text{F-1,6-P}}{\text{F-1-P}}\right)$ was in the range of 3, instead of 1 or nearly 1 as in the hepatic type; this ratio of 1 being that found in the normal liver. We had at that time suggested the following interpretation: hyperaldolasæmia comes from the

tumour itself and it possesses, therefore, a type of aldolase which is different from that found in normal liver. In a preliminary investigation, we have found the ratio of these aldolase activities to be higher in the cancerous region than in the non-cancerous cirrhotic region.

Continuing this work on a new case of human hepatoma, we found a ratio of aldolase activities of 4·1 (ref. 6). We have compared this result with the work on fœtal liver of Hers and Eggermont[7] which we have confirmed.

The present work extends these results to eight cases of human hepatomas and to three experimental hepatomas and seeks to explain their significance.

The experimental tumour is that isolated by Zajdela[8]: an ascites hepatoma, transplanted to adult Wistar rats; the cells are collected seven days after transplant, washed, and homogenized. The samples of human liver are generally removed a few hours after death; some come from biopsy. Animal or human liver is homogenized in 10–20 volumes of water.

The assay for aldolase activity is carried out according to the technique of Sibley and Lehninger[9] which we have adapted (as a micro-method) to the assay for fructose-1-phosphoaldolase activity[10]. These results are expressed in μmole of substrate metabolized per min per g of wet tissue.

Table 1 summarizes aldolase activities of the normal human adult liver and the premature liver; Table 2 summarizes that of rat liver; Table 3 shows the activities of human liver during the course of different pathological states; Table 4, activities during human and experimental primary cancer.

The following facts emerge:

(1) The ratio of aldolase activities is 1, or near 1, in normal adult human or rat liver.

(2) This ratio does not vary *post portem*. It remains equal to, or very near, 1 during benign fructosuria and during the course of viral or toxic hepatitis.

(3) In fœtal liver (human or animal) the ratio of aldolase activities rises to 2 or 3. It rises also, although more slightly, in cirrhosis (M, 1·63 ± 0·21); and much more, as shown by Hers[7,11], in fructose intolerance: we found it to be between 4·6 and 6·7 in four cases.

(4) In human hepatoma, Table 4 shows an anomaly of aldolase, comparable with fructose intolerance because the ratio of the activities is 5·48 ± 1·17 (with the extreme values of 2·2 and 13·0). In the experimental hepatoma of Zajdela, this ratio is between 20 and 50.

The elevation of the ratio of aldolase activities $\frac{\text{F-1,6-P}}{\text{F-1-P}}$ is constant in hepatoma. However, one finds too an increase of this ratio in cirrhosis, in fructose intolerance and in fœtal liver.

The concomitant fibrosis does not explain the rise of this ratio in the course of hepatoma; not only is cirrhosis inconstant, and often moderate in hepatomas, but also in pure cirrhotic liver the ratio rises to an average of 1·6; it is significantly different from the ratio of aldolase activities in hepatoma ($P < 0.02$).

What is the significance of this modification of aldolase activities ?

(1) According to Kaletta-Gmunder, Wolf and Leuthard[12] there exist, in liver, two aldolases, F-1,6-P aldolase and F-1-P aldolase. According to this hypothesis, one would simply find a more rapid disappearance of the second enzyme in cancer. However, one may put forward several arguments against the hypothesis of two enzymes differentiated by their action on two substrates distinct and present in the normal adult liver: a constant ratio of the two activities in several animal species[13] and also a constant ratio during purification and after crystallization[14]; the impossibility, at least at present, of really separating these two activities, either by chromatography[11] or electrophoresis[13].

(2) The comparison with fœtal liver or liver of fructose intolerance brings to mind the ideas of Greenstein[15], for whom the tissular dedifferentiation of a cancer is accompanied by a dedifferentiation of the enzymatic pattern which tends towards a common type. One could suppose that the new enzymatic specificity (proved by the elevation of the ratio of aldolase activities) is expressed by a dedifferentiation at the molecular level. Aldolase would become of the fœtal (or perhaps even embryonic) type in the course of hepatoma: one may notice that in the experimental hepatoma of Zajdela the F-1-P aldolase activity has almost disappeared, and the ratio rises a great deal, meaning, perhaps, a greater dedifferentiation.

Our observations may be compared with those of Starkweather and Schoch[4], who noticed a tendency towards uniformity of the isozymes of the lactic dehydrogenase in cancer of diverse origins.

(3) Hepatic aldolase and muscular aldolase are certainly different; the immunological investigations of Blostein[16] have confirmed this. We can then wonder whether during cancer there appears a new enzymatic specificity, making a molecular disease. However, Nisselbaum and Bodansky[17], examining the properties of the isozymes of lactic dehydrogenase of normal liver and hepatoma, could not show any difference of specificity.

(4) If we accept the hypothesis of Hers that the fœtal aldolase is distinct from the adult aldolase, we

may postulate that in the normal adult this aldolase exists only in trace amounts because its synthesis is repressed by the gene which has become predominant over adult aldolase (in the same way the synthesis of fœtal hæmoglobin is repressed by the gene of the β-chain of adult hæmoglobin).

In cancer the biosynthesis of adult aldolase would be inhibited and also that of the other enzymes very differentiated. The embryonic form of the enzyme would cease to be repressed and could be synthesized in abundant amounts. Such a situation would be comparable with the increase of the biosynthesis of fœtal hæmoglobin in β-thalassæmia. It could be generalized in cancer: all the specialized enzymes of a tissue would disappear, suppressing the repression on the embryonic forms, less differentiated, of the same enzymes.

Further investigations are obviously necessary to appreciate the significance of these facts. In any event, they give arguments for generalizing the concept of the loss of specificity of the enzymatic (or more generally proteic) constituents of tissue in cancer, this loss of specificity being a true molecular lesion.

This work was supported by grants from l'Institut National d'Hygiène, la Caisse Nationale de Sécurité Sociale, le Centre National de la Recherche Scientifique, la Délégation Générale à la Recherche Scientifique, France, the Muscular Dystrophy Associations of America, Inc., New York, and the Damon Runyon Memorial Fund for Cancer Research (grant *DRG*.742).

We thank Profs. Baylon, Debray, Fauvert, Kaplan, Masseyeff, Minkowski, Payet, C. Quenum and Royer, and Drs. J. C. Larroche and Orcel, who supplied us with the samples and gave us the clinical and pathological information. We thank also M. Zajdela for supplying the experimental hepatomas.

AFFINITY OF ANDAMANESE RECENT STONE INDUSTRY

By PRATAP CHANDRA DUTTA

Anthropological Survey of India, Indian Museum, Calcutta, 13

I HAVE recently given detailed accounts of the technology and typology of the stone artefacts recovered from a kitchen-midden site at the Beehive Island in Middle Andaman[1,2]. I have also reported[3,4] the results of my excavation of the kitchen-midden at the village of Chouldari, near Port Blair, in South Andaman. The scope for instituting a study on the affinity of the Andamanese recent stone industry is a rather restricted one, the yield of the artefacts being from a single site. The collection nevertheless provides no less than an important indicator permitting such an attempt. It is now time that an investigation in this line be taken up in view of the present ethnographic interest of the Andamans.

The Andaman Archipelago, comprising some 204 islands and islets, between 10° and 14° N. and 92° and 94° E., is situated in the south-eastern part of the Bay of Bengal. The geographical situation of the Andamans in the mid-waters is highly significant because of its somewhat intermediary position between the mainland of India and that of the Far East Islands including the Malaya Peninsula, both claiming to belong to two main divergent lithi-cultural zones. It would be really interesting to know the probable affinities in the past, if any, of the Andamanese artefacts with either of those two main divergent cultures.

It has already been shown[1,2] that the Andamanese stone artefacts, which have been regarded as belonging to the mesolithic culture, represented a recent flake industry based on blades. The implements are small and were fabricated out of the siliceous rocky elements. While classifying the tool types (Table 1), it emerges that of the major types those constituting the industry were blades, points, scrapers, flakes and plenty of by-products; some true microliths, such as blunted back blade, bladelets, lunates, perforators, also formed part of the collection. The implements (Fig. 1) are mostly primitive showing the crude nature of the workmanship. The ratio of occurrence of finished tools (33 per cent) to by-products (67 per cent) is roughly 1 : 2, which favours the view that the site was possibly a factory site. It is certain that the site was continuously inhabited in the past by the originators of this industry resulting in the formation of the kitchen-midden mound of considerable dimensions.

On the basis of the evidence put forward in course of an exhaustive investigation of the industry[2], one cannot escape the conclusion that the Andamanese stone industry represented a flake and blade industry so characteristic of the mesolithic culture; and the circumstances reported on by me[2], coupled with the material excavated, led to the assumption that the economy of the people was based primarily on hunting and collecting. Other concomitants of this industry were mainly the coiled pottery, fractured and split-up animal bones belonging to *Sus andamanensis* and mollusc shells of Gastropoda and Lamellibranchia, the details of which have already been given[4] elsewhere.

From an examination of the artefacts it is apparent that no such affinity of the present series could be drawn with the types represented in the Indian sub-continent due, no doubt, to the diversity of material techniques. It has been claimed by some investigators[5-12] that the development of the Indian microlithic industries is broadly similar, in some regions, to the types represented in the North African Capsian, Oranian and Sebilian, East African Wilton and, in others, to Natufian of Palestine.

The features of the Andamanese recent stone industry, though lacking in confirmatory details, indicate that the industry shows a considerable resemblance in character

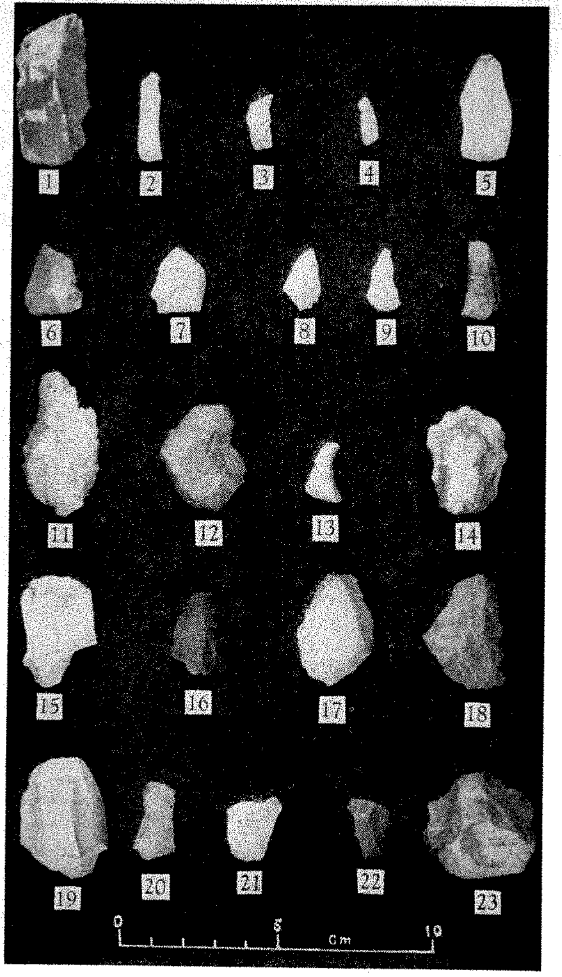

Fig. 1. Nos. 1–5, 10, 13, 20 blades; 6–9, points; 11, 12, 14, 15, 17, 18, scrapers; 21, trapeze; 16, 22, flakes; 19, 23, cores

with the Toalean and allied flake and blade industries of the Far East Islands and South East Asia, claiming, of course, nothing as to their coevality in time.

The flake and blade industry was classically developed in south-western Celebes[13], which included artefacts, such as flakes, blades, knives, arrow-heads and some true microliths. This particular industry is more commonly known as Toalean after the existing Toal Aborigines of Celebes. The flake and blade industry has also been found in the Djambi District[14], on the east coast of Sumatra[15], and on the Bandung Plateau in western Java[16,17]; and van Heekern[18] also traced a related industry of secondary importance, associated with the Sampung Bone culture, in western Java. Evans[19] reported on the occurrence of mesolithic flakes in Borneo, whereas Sarasin[20] recorded the flake industries of the Lesser Sunda Islands, and later, Verhoeven[21] discovered implements belonging to the flake and blade industry in West Flores.

The site at Tanjong Bunga, which is situated at the tip of the Malayan Peninsula, yielded so far the only Malayan artefacts[22] which could possibly be recognized as representative of the flake and blade culture. The obsidian implements from Luzon[23] and the artefacts, such as scrapers, small knives, awls and crude points from Rizal Province[24] of the Philippines, belonging to the mesolithic culture, are comparable with the present series.

Clark[25], like others, also observed "that these industries came to be identified with hunting peoples of Negrito stock . . .". The Aborigines[26–38] of the Andaman Islands are a very dark, very short, brachycephalic people having pepper-corn pattern of hair and infantile characteristics.

In this context, attention should be directed to the ethnic affiliation of the Andamanese. To mention the view of Lapicque[39], who worked intensively on the problem of Negritos of South East Asia including Andamans, that the people of the Andamans bear similarities in physical features with Negritos of South East Asia. Martin[40] and Sullivan[41], both of whom examined the craniological evidence, discussed in detail the racial affinities of Andamanese with the Semang of Philippines and were of opinion that the people of Andamans and Philippines originated from the same racial stock. Nippold[42] also sought a common origin of the people of both groups of the Islands from South East Asian pygmies.

But how and when they came to inhabit these widely separated Islands from the mainland of Asia is still a matter of controversy. Kaudern's[43] observations, however, based primarily on Molengraaff's[44] researches on the rise and fall in sea-level during the prehistoric period, suggested that the migrations of the pygmies occurred directly from Asia to both the Andamans and the Philippines in the Quaternary Age during glacial periods.

It may, therefore, be admitted that the recent stone industry of the Andamans, which represented a flake and blade industry of the mesolithic stage of culture, was broadly similar in character to the Toalean and allied flake and blade industries of the Far East Islands. It seems, however, in all probability, when more material becomes available, that the Andamanese industry may bring to light some genetic relationship with those of the Far East Islands including South East Asia. The geography and the environment of the Andaman Islands are such that they caused the survival of the mesolithic stage of culture and the hunting and collecting economy from the early period down to comparatively recent times.

LETTERS TO THE EDITOR

ASTROPHYSICS

Active Dark Filaments and Type III Bursts

At the Ondrejov Observatory, simultaneous observations of a spectrohelioscope by L Krivsky and radiometers at 231 and 260 Mc/s by A Tlamicha were made, showing a clear time coincidence between a type of group of bursts, even when the duration is short, and active dark filaments without flare in more than 15 cases during 1960–62 This type of group of bursts referred to as type N_A (and N_B) (ref 1) is a group of short duration bursts without remarkable enhancement of base-level

In order to identify the spectral type of these bursts, the same type of groups of bursts recorded at the Tokyo Astronomical Observatory with a polarimeter at 200 Mc/s has been compared with the spectral data (15–210 Mc/s) obtained at the Dapto Station, Sydney The foregoing type of bursts seems to be the group of type III bursts Almost all the identifications were made by using a list of the spectral observations *Spectral Classification of Solar Activity*, Dapto, Sydney, but some of them were already identified with type III bursts by a direct comparison with the spectral records by the courtesy of the Sydney group, and also these bursts are almost unpolarized as the type III bursts at 200 Mc/s usually are

In order to certify the correlation between the active dark filaments and type III bursts, active prominences and active filaments (without flare) observed in 1960 with a spectrohelioscope has been compared with radio activities observed with an interferometer and a polarimeter at 200 Mc/s at the Tokyo Astronomical Observatory Even though the number of the optical observations is quite small, a good coincidence in position is found in 5 of 6 cases between the active prominences (and active filament) without flare and groups of type III bursts at 200 Mc/s occurring in the periods of the optical activities The number of association of the type III bursts with the optical activities is 8 out of 21 despite the fact that the high-frequency cut-off for type III bursts may sometimes occur below 200 Mc/s and that the radio waves from the extreme limb may not be observed (Table 1)

Table 1

Active prominences	No of events	No of association	Type III group at 200 Mc/s Coincidence in position	No observation in position	No coincidence in position
Prominence	20	7	4	2	1
Filament	1	1	1	0	0
	21	8	5	2	1

During the periods of the active prominences and active filaments already mentioned, 27 out of 33 cases have type III groups given in the list of *Spectral Classification of Solar Activity*, Dapto, Sydney, in some frequency ranges between 210 Mc/s and 15 Mc/s, although chance coincidences may be included and also the sensitivity of the spectrometer is not enough to record weaker type III bursts

These results may support a statistically significant, but small, correlation, which has been shown by G Swarup, P H Stone and A Maxwell[2], between surges without flares and fast-drift bursts observed with spectrometers The correlation is probably better if more weaker type III bursts were able to be recorded C S Warwick[3] has shown a good correlation between large ascending prominences and radio activities at 200 Mc/s J P Wild and H Zirin[4] have reported that, in some cases, limb surges were associated with groups of type I bursts These groups of bursts shown in their paper, however, seem to us to be groups of type III bursts

In order to derive a more definite conclusion, we should like to point out the importance of observations of active dark filaments and active prominences with spectrohelioscope using line shifter, taking a direct contact with radio observations with interferometer, more sensitive spectrometer and polarimeter Both the starting and the location to be observed by the helioscope can be determined by radio observations

We thank Mr Kai for help in the determination of radio positions

PHYSICS

Sodium-24 produced by Cosmic Radiation

Cosmic radiation produces several radioactive nuclides by spallation of atmospheric argon Some of them have been detected, first phosphorus-32 in rain-water[1], then sulphur-35 (ref 2) and afterwards phosphorus-33 (ref 3) Sodium-22 was also found[4] in spite of its very low yield caused by the large mass difference compared with argon-40 Furthermore, Winsberg[5] succeeded in finding the short-lived nuclide chlorine-39 (55 min half-life)

The success in detecting sodium-22 and chlorine-39 suggested that it might also be possible to find sodium-24 (15 h half-life) which had not so far been detected It was to be expected that the production rate would be of the same order as that of sodium-22 and that the yield in rain would be sufficient for measurement

Indeed sodium-24 has been detected in several rains for the first time during the work recorded here

A detector had to be designed with an appreciable efficiency and a very low background Nearly 100 per cent of sodium-24 decay by β^--emission ($E_{\max}$ 1 4 MeV) to a 4 12-MeV level of magnesium-24 The de-excitation from this level to the ground-state is associated with a γ-cascade of 2 75 MeV and 1 37 MeV The 2 75-MeV ray was measured by a 4 in × 2 in sodium iodide (Tl)-crystal with a bore-hole of 2 in diameter and 0 5 in depth The 1 37-MeV peak cannot be used because it is obscured by the 1 28-MeV peak and the Compton distribution of the 1 79-MeV sum peak of sodium-22 always present at the same time To reduce the background the β-radiation is measured in coincidence by a flow counter which extends into the bore-hole of the crystal Except for the bottom the detector is surrounded by a guard counter in anticoincidence to eliminate the effects caused by cosmic ray mesons The whole detector unit is screened by 5 5 in lead The counting efficiency of the arrangement is 1 4–1 7 per cent (depending on the β-absorption in the sodium chloride layer of the sample), the background being 0 22 c p h or 0 003 c p m The crystal itself has a counting efficiency of 4 per cent and a background of 72 c p h or 1 2 c p m

Rain-water was collected over an area of 8 6 m^2 and put through an ion-exchange column of 6 cm diameter and 52 cm length filled with 'Dowex' cation exchange resin, 50 × 8, 50–100 mesh The sodium was eluated selectively by 0 67 N hydrochloric acid A first fraction of effluent amounting to 4 0 l was discarded, the subsequent fraction of 2 9 l contained about 98 per cent of the sodium The eluate was evaporated to dryness, dissolved again, and aluminium chloride added Aluminium was precipitated with diluted ammonium hydroxide Na^+ remained in solution whereas other ions, if present, were precipitated almost entirely with the aluminium hydroxide The solution containing the sodium was evaporated to dryness Finally, the ammonium salts were removed by heating The sample was transferred to the counting device as crystallized sodium chloride

The sodium-24 was identified not only by its γ-radiation but also by its life-time The decay was measured for three half-lives The results exclude an essential error in measurement (exceeding the statistical error) caused by possible spurious contributions of thorium *B* and its daughters (2 62-MeV peak)

Three samples were measured on June 7, 1963, from 248 l of rain-water an activity of 0 18 ± 0 02 d p m /l or 235 ± 25 atoms/l , on July 4, 1963, from 203 l of rain-water an activity of 0 35 ± 0 03 d p m /l or 455 ± 40 atoms/l , on October 7, 1963, from 330 l of rain water an activity of 0 19 ± 0 03 d p m /l or 245 ± 40 atoms/l

The fact that the concentration does not vary considerably with season confirms that the stratospheric contribution if any is small

According to Lal and Peters[6] a tropospheric production rate of about 6×10^6 atoms/m^2 year can be estimated for sodium-22 in the geomagnetic latitude of Heidelberg and therefore for sodium-24 also When the concentration values given here are converted to mean annual rainfall at Heidelberg, a deposition of about 2×10^5 atoms/m^2 year is obtained for sodium-24 Because of the short half-life it was to be expected that only a small fraction of the produced activity could be detected at ground-level

I thank Prof O Haxel and Dr G Schumann for facilities for this work and for advice

Measurement of Surface Tension by Interferometric Means

FOR a sessile drop of liquid of surface tension, density and radius of curvature R_0 at the vertex, the differential equation[1]

$$y'' = (2+\beta y)\,[1+(y')^2]^{3/2} - \frac{y'}{x}[1+(y')^2],\ \beta = g\rho R_0{}^2/\gamma$$

for drop shape (Fig 1) in terms of the co-ordinates measured from the vertex and scaled with respect to R_0, has recently been solved numerically on a digital computer by Staicopolus[2] and the *Fortran II* programme is available The method used is more accurate than the elaborate approximation procedure of Bashforth and Adams[1] and, although not mentioned by Staicopolus, the results are also more accurate than Porter's[3] values of $\gamma/\rho gr$ as a function of h/r The results allow γ and r/R_0 to be related to h and r through a polynomial expression in $z = (r/h - A)/C$

A and C being constants, 1 5922 and 0 5922 respectively

The accurate expressions plus further use of the computed data enable γ to be determined for small drops and bubbles using an interference microscope to obtain r/h from r/R_0, thus avoiding the usual requirement of a direct accurate measurement of h with its attendant difficulty[4]

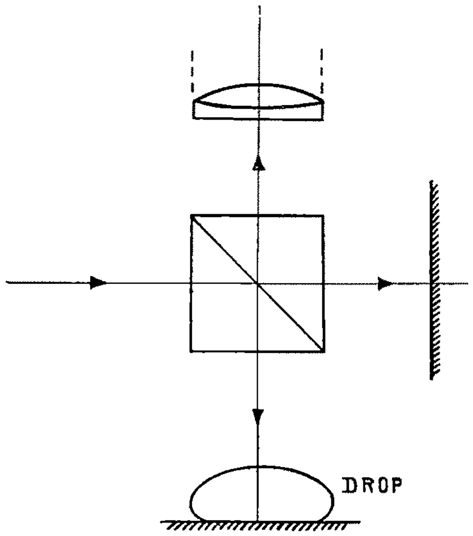

Fig 1

From a measurement of r and R_0 and the digital computer results, h/r can be determined accurately to four decimal places after fitting an expression $z = f_2(1 - r/R_0)$ in the same way as the inverse form[2] $r/R_0 = f_1(z)$ A fourth-order polynomial (Table 1) gives this accuracy for small drops where $r \sim 0(R_0)$ This method improves on h/r determined from r/R_0 assuming the elliptical approximation[5] for the surface above the plane of greatest section, since that approximation does not always hold to the accuracy required

Table 1

Polynomial coefficients

$$z = (r/h - A)/C = \sum_{n=0}^{4} a_n\,(1 - r/R_0)^n$$

a_0	−1 0000
a_1	2 2755
a_2	−0 3056
a_3	0 2620
a_4	0 0571

Having obtained h/r from $z = f_2(1 - r/R_0)$ the value of γ is found by substitution into the polynomial expression $\gamma = g\rho R_0{}^2/B(z)$ given by Staicopolus[2]

An interference microscope (Fig 1), embodying the Michelson principle[6], was used at times 26 in measurements on small samples of glycerol and related liquids The formulæ for the radius of curvature by Newton's rings were used since it is relatively simple to show that for small drops or bubbles ($r \sim$ 0 5 mm) the curved surface over the small region (radius 0 07 mm) at the vertex which is observed in the interference microscope may be taken as spherical to the required degree of approximation, that is, the actual surface and the assumed spherical surface do not differ by more than a small fraction of a wave-length of light

The method of least squares was used to determine R_0 from the experimental observations made using the green 5461 Å line from a mercury 198 lamp The accurate magnification for the reduction of measurements made on photographic plates was obtained by repeated measurements on a 1-mm scale photographed alongside the drop and which was precision ruled into 10 divisions on a metrological ruling engine at the National Standards Laboratory, Sydney

For typical cases of small sessile drops, 1 mm radius, of glycerol, r was measured to ± 0 0001 cm and R_0 to ± 0 00005 cm, allowing γ to be determined as 61 5 ± 1 dynes/cm at 25° C

The method is particularly useful when only small samples are available. It also applies to sessile bubbles and allows the surface tension between a liquid and a gas to be measured conveniently under difficult conditions sometimes encountered.

The experimental observations were made while I was at the Commonwealth Scientific and Industrial Research Organization, Sydney.

OCEANOGRAPHY

Measurements of Equatorial Currents in the Gilbert Islands Area, July – August 1963

IN a recent article, Montgomery[1] reviewed the observations of the equatorial undercurrent, a current which has been recorded at least seasonally in each ocean. This easterly flow is found near the equator, usually below a westerly surface current; the easterly velocity maximum is located within the thermocline. Measurements in the central Pacific Ocean have shown the undercurrent commonly to be separate from the easterly surface flow of the equatorial countercurrent to the north, to be symmetrical about the equator, to be relatively steady, and to have a maximum velocity of two to three knots. In the western Pacific Ocean, on the other hand, the data indicate that the undercurrent is by comparison less strong and less steady, is commonly not symmetrical about the equator, and is often joined to the equatorial countercurrent by a continuous layer of easterly flow. Montgomery chose the Gilbert Islands, which cross the equator at 174° E., as the natural dividing line between the central and western regions of the equatorial Pacific Ocean. This chain of islands apparently forms the only sizeable obstruction to the flow of the undercurrent between New Guinea and the Galapagos Islands, a distance of some 8,000 miles.

The previous measurements of the current happen to have been made mostly well to the east or west of this dividing line, with few data from the vicinity of the Gilbert Islands and no measurements within the inter-island channels themselves. To provide a first look at this interesting area, a programme of water sampling and current measurements was added to the hydrographic survey carried out in the Gilbert Islands during July–August 1963 by H.M.S. *Cook*, the Royal Navy surveying ship, in the south-west Pacific Ocean.

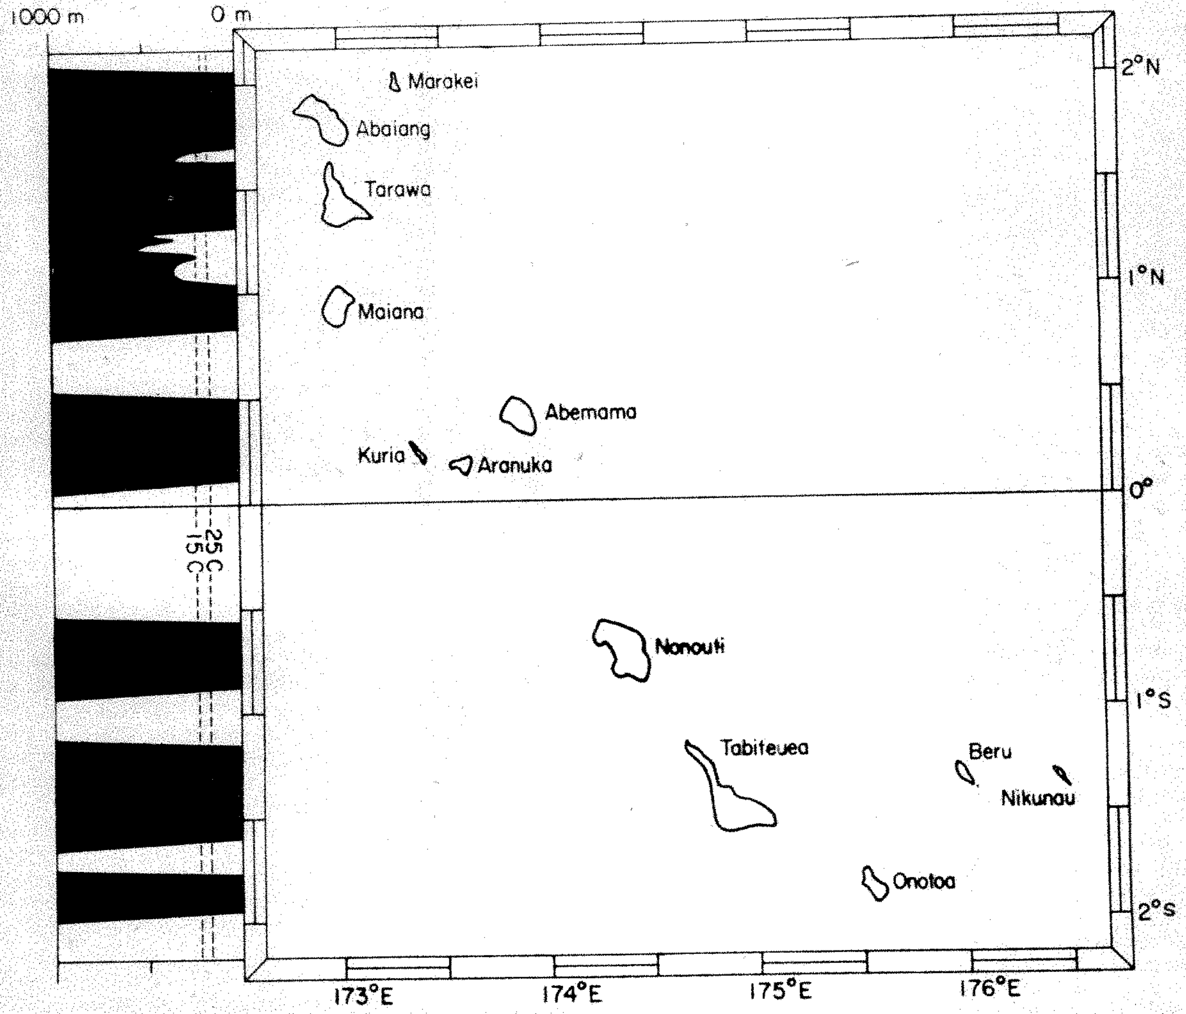

Fig. 1. Right panel, chart of the central Gilbert Islands. The approximate outlines of the shoal areas are shown; the small islets, which mostly lie along the eastern reefs of the atolls, are not depicted. Left panel, profile of the island chain, from the sea surface to a depth of 1,000 m, projected on a meridional plane. Latitude scale same as for right panel; vertical exaggeration 200. Isotherms for 15° C and 25° C are from bathythermograph data taken along 169° 34′ E. Fig. 1 is drawn from U.S.N.H.O. chart No. 0119 and from unpublished recent surveys by H.M.S. *Cook*

The Gilbert group includes both atolls and lagoonless coral islands. Of varied size and shape, the islands rise only a few feet above sea-level and for the most part fall away steeply (and often with spectacular suddenness) to oceanic depths. A chart of the central Gilbert Islands is shown in Fig. 1. This figure also includes the profile of this portion of the island chain, between the sea surface and a depth of 1,000 m, as projected on a meridional plane. The positions of the 15° C and 25° C isotherms included on the profile were observed on a meridional section at the longitude of Ocean Island, some 250 miles west of the Gilbert Islands (see following). These isotherms define the extent of the main part of the thermocline in this region; it is seen that there are no extensive obstructions in the inter-island channels at depths which would interfere with zonal flow at the level of the thermocline.

While the Gilbert Islands lie within the limits of the easterly trade winds, light airs and calms are much more common than in the region along the equator in the central Pacific Ocean. (During the cruise reported here, calms or light airs were reported on 31 of the 46 days spent in the general vicinity of the island group.) The surface currents, while generally setting toward the west, are notorious among island navigators for the occasional occurrence of strong sets in unpredictable directions, causing difficult landfalls on these low islands (personal communications and experience). It should also be noted that the spring tide range in these islands is of the order of 2 m, so that one might expect occasionally to find tidal currents influencing the flow in the vicinity of land.

In the expectation of complex flow in the neighbourhood of the islands, it was decided that H.M.S. *Cook* should first look for the undercurrent by occupying a meridional section well upstream (westward) from the island chain. This section was made along 169° 34′ E., the longitude of Ocean Island (a small, isolated, raised coral island at 0° 53′ S., which H.M.S. *Cook* had, in any event, to visit for bunkers). Stations were occupied every 30 miles from 2° S. to 3° N., with serial measurements of water properties and currents to 800 m. Following completion of the meridional section, three 24-h stations were occupied along the same longitude, approximately at 1° 00′ N., 0° 15′ N., and 0° 30′ S. During each of these three stations the drift of the vessel relative to an anchored beacon was measured by radar. Serial current measurements to 400 m were repeated every 3 h, with serial measurements of water properties to 800 m at the beginning and end of each 24-h station.

The bathythermograph data from the meridional section demonstrate the equatorial spreading of the thermocline associated with a geostrophic undercurrent[1]. The vertical separation between the temperatures of 15° C and 25° C was 60 m at 2° S. and 45 m at 2° N., but at the equator it reached a maximum of 88 m. Preliminary examination of the data from each of the three 24-h stations reveals that easterly flow was present in the thermocline, the mean eastward component not exceeding 1 knot at any depth. While the details of the surface current will have to await a thorough analysis of the effect of the wind on the ship, it can be said that the surface current, regardless of direction, was uniformly slower than the current in the thermocline, and also that during the station at 1° N., which had a preponderance of calms and light airs, the mean surface current had an eastward component.

After completion of the work at 169° 34′ E., H.M.S. *Cook* returned to the Gilbert Islands, where two further 24-h stations were occupied, one in the centre of the Maiana–Kuria channel and the other in the centre of the Aranuka–Nonouti channel. The mean flow in the thermocline was easterly at both stations, with the eastward component not exceeding 1 knot. The surface currents were weaker than the sub-surface flow, and under calm conditions in the Maiana–Kuria channel the surface current had an eastward component.

This work has done little more than make a first identification of the equatorial undercurrent in the Gilbert Islands. It is clear that this area would be a fruitful one for further studies of the equatorial circulation, and of the undercurrent in particular.

The participation of one of us (E. D. S.) in this programme was supported by the U.S. National Science Foundation and Office of Naval Research.

X-ray Emission Spectroscopic Investigation of Sealing of Anodic Oxide Films on Aluminium

'Sealing' of oxide coatings produced on aluminium and its alloys by anodic treatment in sulphuric acid solutions is the reaction between the amorphous alumina (containing about 15 per cent sulphate) and boiling water or aqueous metal salt solutions. X-ray emission spectroscopy provides a new and useful technique to study the sealing reaction through its quantitative and quick determination of the content of various elements such as aluminium and sulphur in the film and their changes on sealing. Sealing action in metal salt solutions of nickel acetate, cobalt acetate or potassium dichromate can be assessed by the increasing metal ion content of the sealed film. Typical results are discussed here.

The emissivity radiation strength under standard examination conditions is affected by: (*a*) element volume concentration in the oxide film; (*b*) film thickness; (*c*) absorptivity of the film (including action of the water or metal salts taken up in the sealing operation). The volume concentration of the element examined is not changed significantly by sealing since chemical dissolution of the film is very slight, and no volume change can be detected (by normal metallographic techniques). The influence of film thickness remains essentially constant once a minimum film thickness is attained. (Rough calculations indicate that with aluminium and sulphur, 90 per cent of maximum intensity is attained with film thickness of about 4μ.) This leaves absorptivity as the major variable during an examination of sealing. Thus, with anodic coatings produced under standard conditions to an adequate film thickness and sealed in various ways, the aluminium and sulphur counts will decrease on sealing in water, compared with values for the non-sealed film, and will vary with the degree of sealing, that is, with differences in the take-up of water.

The X-ray emission spectroscopy technique has been applied successfully in a study of sealing. A General Electric X-ray spectrograph (*XRD*–5) was employed using the following spectral lines, aluminium *K*–α (8·34 Å), sulphur *K*–α (5·37 Å), nickel *K*–α (1·66 Å), with operating conditions standardized to yield 4,000 c.p.s. for high purity (99·993 per cent) aluminium spectrographic standard.

Aluminium (99·998 per cent) foil samples in groups of 10 panels each were anodized in 15 per cent sulphuric acid solution at 25° C and 15 amp/ft.^{2} for 45 min to yield oxide films with coating weights of 4·5 mg/cm^2 (film thicknesses of about 20μ). Individual weighed panels from a group were sealed in de-mineralized water (*p*H 6·0, 100° C) or nickel acetate solution (nickel acetate 5 g/l, boric acid 5 g/l, *p*H 5 0, 100° C) for varying periods up to 3,000 min The weight gain on sealing was determined, followed by X-ray emission spectroscopy determination of aluminium, sulphur and nickel intensities Panels were stripped of all oxide by treatment in the conventional phosphoric acid–chromic acid solution (A S T M *B* 137-45) at 100° C for 10–15 min, the aluminium panel weight determined and the unsealed coating weight and the per cent weight gain on sealing calculated

The change in aluminium and sulphur radiation intensities as the oxide film was thinned by progressive chemical dissolution in the phosphoric–chromic acid solution was also investigated A group of panels was anodized and sealed together, and then individual panels were immersed in the hot acid solution for varying periods of 15 sec–15 min followed by examination by X-ray emission spectroscopy The loss in weight during dissolution treatment was determined by weighing, after which the samples were treated further to remove the oxide completely The percentage weight of film dissolved was calculated for individual panels

The gain in weight during water sealing (Fig 1) rose with time, but at a steadily decreasing rate, up to 3,000 min, a period more than 50 times longer than the sealing period in commercial use for films of this thickness The aluminium intensity decreased, rapidly at first, and then at a slowly decreasing rate The intensity was linear with the percentage gain in weight on sealing The sulphur emission intensity also decreased, but to a lesser degree and was not linear with the gain on sealing

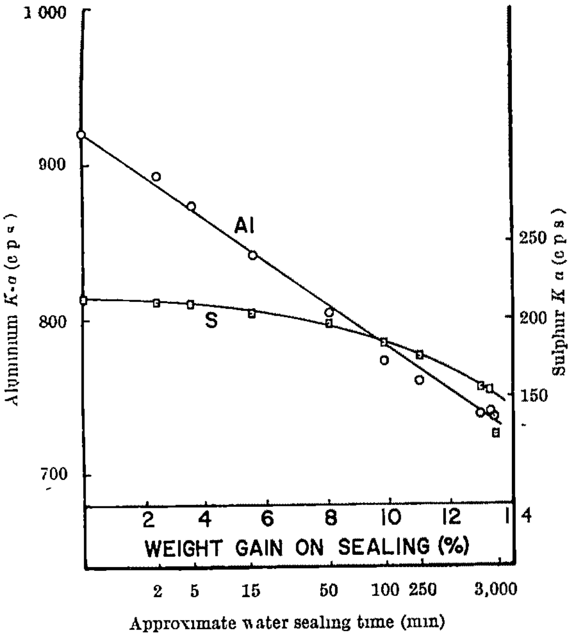

Fig 1 Effect of water sealing time on X-ray emission spectroscopy intensities for aluminium and sulphur (100° C, *p*H 6 0)

The results obtained with nickel acetate solution sealing (Fig 2) were very different from those from water sealing The gain in weight on sealing for the maximum period used (250 min) was much higher than in water sealing (24 per cent versus 11 per cent) due to precipitation of nickel salts during sealing in addition to water take-up The aluminium intensities decreased linearly with percentage gain in weight on sealing during sealing for up to about 30 min and then decreased more slowly Nickel intensities increased linearly during the entire sealing period but with a change in rate after about 30 min of treatment The addition of specific surfactants to the nickel acetate solution has been found to modify greatly the effect of sealing on the X-ray emission spectroscopy values Further work is required to confirm and explain these results

The effect of progressive dissolution of the film on the aluminium and sulphur intensities is illustrated by Fig 3 The values for unsealed films were aluminium, 920, sulphur, 230 c p s These were much higher than the

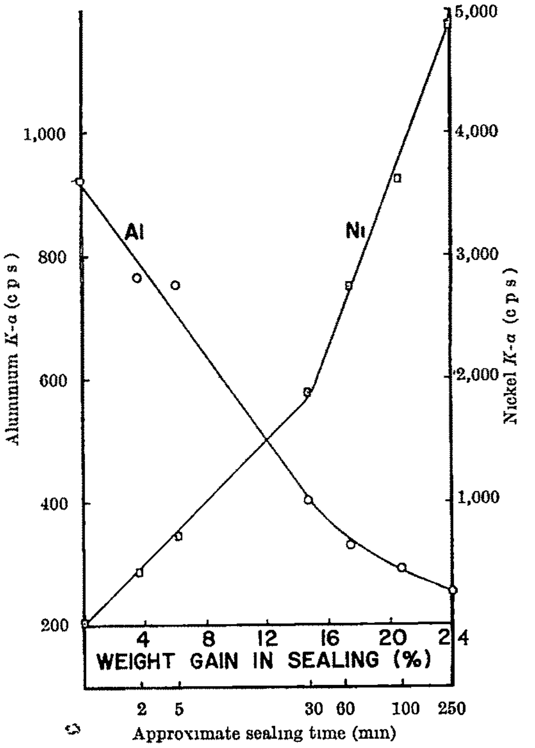

Fig 2 Effect of sealing time in nickel acetate solution on X-ray emission spectroscopy intensities for aluminium and nickel (nickel acetate 5 g/l, boric acid 5 g/l, *p*H 5 0, 100° C)

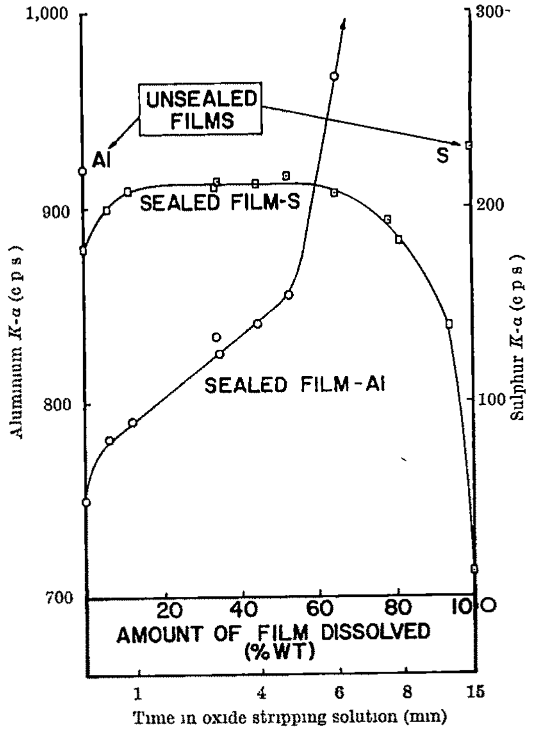

Fig 3 Effect of progressive chemical dissolution of water-sealed anodic oxide film on X-ray emission spectroscopy intensities for aluminium and sulphur (sealed 250 min, 100° C, *p*H 6 0)

counts determined on the samples which had been water-sealed for 250 min, namely, aluminium, 750, sulphur, 180 c p s As individual samples were 'stripped' for increasingly longer periods the aluminium intensity rose to 855 with accompanying loss in weight of about 50 per cent of the oxide film With further stripping the intensity climbed very sharply due to increasing contribution not of the oxide film but of the aluminium substrate which was not screened out by the greatly thinned oxide film

The change in sulphur intensities with increasing dissolution of the film showed an initial rise to a value which was maintained until the increasing thinness of the oxide coating caused a decrease (as compared with the rise with aluminium intensities)

The initial rise of both aluminium and sulphur intensities appears to be due to the presence of a 'skin' of oxide which was sealed to a greater degree than the underlying bulk film The depth and degree of this effect increased with sealing time Similar effects have been noted in work with oxide films sealed in nickel acetate solution Dissolution in the chromic–phosphoric solution probably causes non-uniform thinning due to differential action associated with the pore structure of the anodic oxide coating Non-uniform attack of barrier layer films by the same solution has been discussed by Altenpohl[1], Franklin[2], and Stirland and Bicknell[3] Examination of the location of the dissolution action and of the 'skin' effect is continuing

MINERALOGY

A Mercury Mineral from the British Isles

WE have recently discovered small quantities of cinnabar (HgS) in the galena–calcite–fluorite ore-bodies of Rutland Cavern, Matlock Bath, Derbyshire The mineral occurs in cavities, most often in fluorite, as a brick-red deposit associated with smithsonite ($ZnCO_3$) and iron-staining, and under the microscope appears as minute red specks dusting the surface of smithsonite and fluorite This is the first recorded occurrence of a mercury mineral from the British Isles Since our discovery cinnabar has also been identified on a specimen from Peat Pasture, Greenhow Hill, Pateley Bridge, Yorkshire, in the collection of Sir Arthur Russell, Bart

We thank the staff of the British Museum (Natural History) for carrying out the identifications

CHEMISTRY

'Ageing' of Silica Suspensions in Water and its Influence on Flocculation by Polyacrylamide

IT has been found that silica and certain silicates undergo a slow change of surface properties when kept in water, their suspensions becoming resistant to flocculation by polyacrylamide For example, fresh 1 per cent suspensions of the high-purity, amorphous silica 'Aerosil' (Degussa, Germany) are rapidly flocculated by a 0 004 per cent solution of polyacrylamide of high molecular weight, such as 'Cyanamer *P* 250' (American Cyanamid Co , New York), but, after standing for a certain time, 'Aerosil' suspensions can no longer be flocculated, even by larger amounts of polyacrylamide (for example, 0 08 per cent) Fig 1 shows the times required to develop resistance to flocculation in various solutions

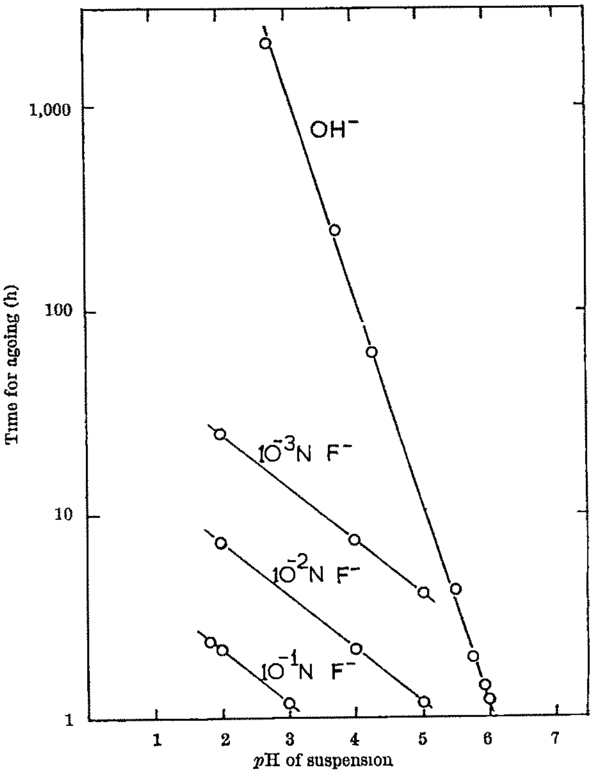

Fig 1 Times of ageing of silica, in aqueous suspensions, required to develop complete resistance to flocculation by polyacrylamide

The 'ageing' effect has been proved not to be due to dissolution of silicic acid or to changes of surface area The silica can be restored to its original (flocculable) condition by heating it to 300° C, this treatment removes chemisorbed water present as silanol groups, whereas removal of physically adsorbed water at lower temperatures does not reverse the ageing Infra-red spectroscopy on samples heated to various temperatures showed that a band at 2 74μ, which has been ascribed to single hydroxyl groups[1], is present in the original and in the 'rejuvenated' silicas but not in the aged forms dried at temperatures below 300° C This band also disappears in fresh silicas that have been flocculated by polyacrylamide

Polyacrylamide is strongly adsorbed by fresh silicas but not by aged ones Adsorption evidently occurs by hydrogen-bonding on to silanol groups, because flocculation was inhibited when competing hydrogen-bonding agents such as alcohols, amides, ketones and ureas were added, furthermore, the relative molar effectiveness of these agents was found to be independent of the concentration of polyacrylamide, and their order of effectiveness agreed closely with their interaction values with silicic acid[2]

Powdered quartz and talc showed a similar ageing, whereas alumina, bentonite and kaolinite showed no ageing, remaining sensitive to flocculation Ageing therefore appears to be associated with surfaces that are predominantly siliceous in composition

In the *p*H range 2–6, the rate of the ageing process is proportional to the concentration of hydroxyl ions (Fig 1) Fluorides also accelerate ageing, though less strongly than OH^-, while chloride is quite ineffective The rate with fluoride is roughly proportional to $[F^-]^{\frac{1}{2}}$

and depends somewhat on *p*H, presumably because hydrogen fluoride is not fully dissociated

From this evidence two conclusions may be drawn

(1) Flocculation of silica by polyacrylamide occurs by hydrogen-bonding adsorption on silanol groups of a particular type—probably isolated OH-groups

(2) Ageing of silica in water is a chemical reaction in which these active groups disappear

A co-ordination number of silicon above four can occur in the presence of hydroxyl or fluoride ions[3], also, an increase of number of OH-groups carried by each silicon atom in the surface layer has been found[4] Although it is not yet clear why adsorption of polyacrylamide is thereby prevented, the hydrogen-bonding ability of surface silanol groups must be involved The presence of a co-ordinately bonded hydroxylic layer seems a plausible hypothesis[5]

The ageing phenomenon may also have important implications for the biological action of silica, fresh silica is flocculated by a very small amount of human saliva, while aged silica is not

One of us (O G) thanks the University of Buenos Aires for a fellowship held during the course of this investigation

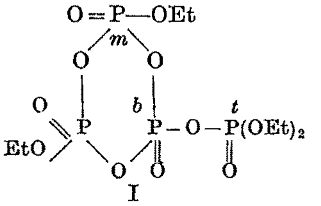
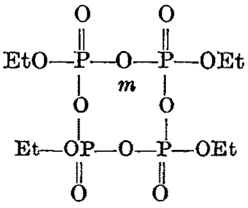
Structure and Mechanism of Hydrolysis of the Product of Reaction of Phosphorus Pentoxide and Ethyl Ether

THE product of reaction of phosphorus pentoxide and ethyl ether which has the composition of a metaphosphate ester $[PO_3(C_2H_5)]_n$ has been the subject of recent discussion Ratz and Thilo[1] have shown that the product of hydrolysis of this ester could result from the splitting of a mixture of the two following compounds



I

and



II

However, the nuclear magnetic resonance spectrum obtained by Van Wazer[2] on the crude compound shows the presence of three peaks, the chemical shifts of which are characteristics of terminal (*t*), middle (*m*) and branched (*b*) phosphorus atoms, but in the proportions P_t = 25 per cent, P_m = 72 per cent, P_b = 3 per cent The inequality of P_b and P_t seemed to rule out the proposed structure

The use of this compound as an activating agent in a number of condensation reactions[3] has indicated its extraordinarily high reactivity towards OH groups and raised the question of the mechanism of the condensation reaction The titration of a solution of the polyphosphate ester in water immediately after dissolving shows two primary acid groups for each initial P_4O_{10} molecule (Fig 1, curve 1) Pollmann[4] has examined the changes in infra-red spectra of a solution in chloroform on addition of small quantities of water and suggested an opening of a ring based on the disappearance of a broad peak attributed to cyclic metaphosphate

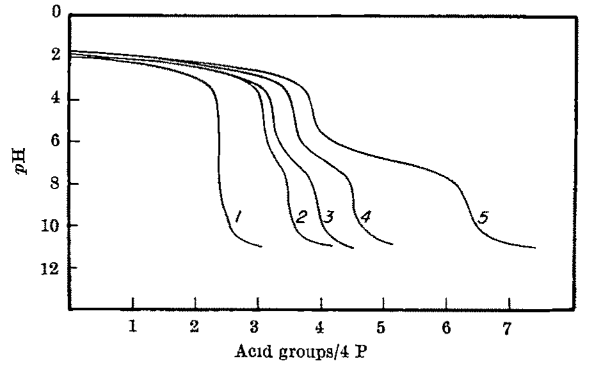


Fig 1 Titration of the polymetaphosphate ester in water as a function of time (1) immediately after dissolving, (2) after 6 h, (3) after 24 h, (4) after 52 h, (5) after boiling for 1 h

The nuclear magnetic resonance technique seemed suitable for a fine analysis of the structure and mechanism of hydrolysis of this compound We have used a Varian spectrometer operating at 24 5 megacycles/sec Phosphoric acid (85 per cent) was used as an external standard and no attempt was made to measure the chemical shift with an accuracy of better than ± 2 p p m

A first attempt to reproduce Van Wazer's experiment on an undiluted sample prepared a few days before the observation has given the result shown in Fig 2 The chemical shifts are identical to those published by Van Wazer $\delta P_t = 16$, $\delta P_m = 29$, $\delta P_b = 42$, and the proportion only slightly different from his with an unequal proportion of P_b (6 per cent) and P_t (32 per cent)

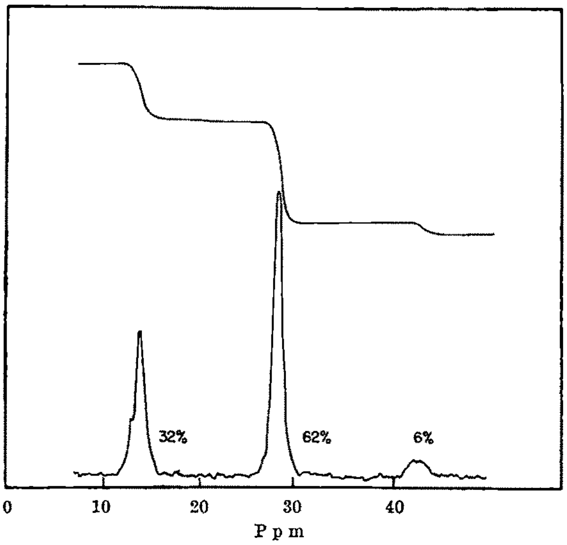

Fig 2 Nuclear magnetic resonance spectrum of a crude sample of polymetaphosphate ester and integration curve (no solvent)

To prevent a partial hydrolysis during the storage or the transfer of the viscous material into the narrow tube, we have introduced directly into the tube a freshly prepared chloroform solution of the compound in the absence of humidity, and evaporated part of the solvent under vacuum The spectrum so obtained (Fig 3*a*) and its integral (Fig 3*f*) show approximately equal proportion of P_b and P_t and therefore permits structure I The relative amounts of phosphorus in structures I and II can then be calculated

$$C_{I} \sim 2 \times (15 + 13 \text{ per cent}) = 56 \text{ per cent}$$
$$C_{II} \sim 44 \text{ per cent}$$

The changes of the spectrum on addition of small quantities of water (Fig 3*b*, *c*, *d*, *e*) reveal the following features

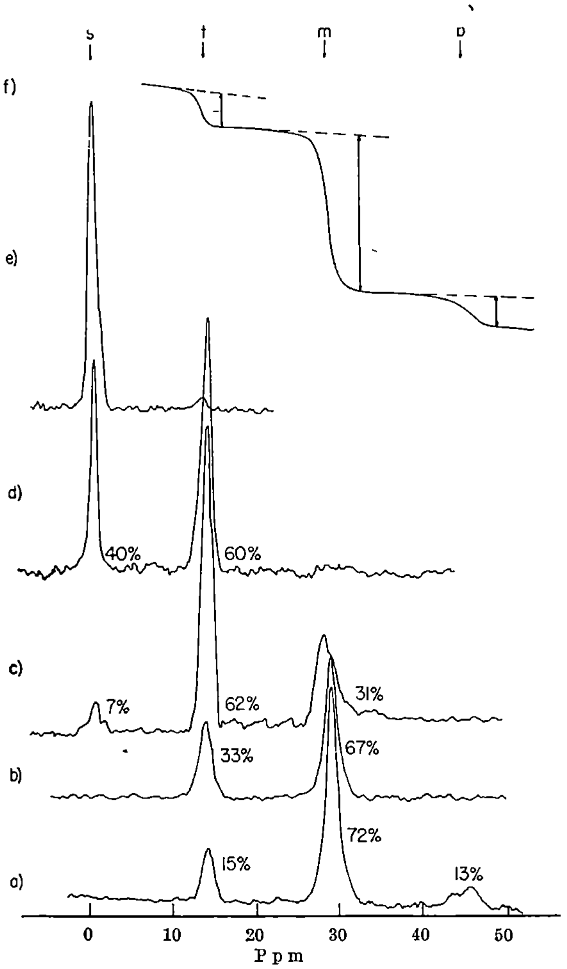

Fig 3 Nuclear magnetic resonance spectrum of a concentrated solution of freshly prepared polymetaphosphate ester in chloroform *a* and *f*, Sample in absence of water and its integral, respectively, (*b*) with less than one equivalent of water per 4 P, *c*, with a large excess of water after 5 h, (*d*) with an excess of water after 20 h, *e*, with an excess of water after boiling (each trace may be at a different amplification)

(*a*) In a first step (*b*) the P_b peak disappears and the P_t peak increases while P_m remains practically constant No resonance corresponding to orthophosphate derivatives appears

(*b*) In a second step (*c*) the concentration of P_m decreases and the concentration of P_t increases until both are roughly equal

(*c*) The concentration of P_t becomes higher than P_m and a small quantity of orthophosphoric derivative (P_s) is found (*c*) followed by a disappearance of P_m with increasing amounts of P_s(*d*)

The same experiment performed with ethyl alcohol gives the same pattern of results From the relative amounts of the different species of phosphorus during these three steps, the following conclusions are drawn

(*a*) The structure I is more sensitive to hydrolysis than structure II The first bond to be split is the bond connecting the 'branched' phosphorus to another phosphorus of the ring

(*b*) The ring opening of structure II follows until transformation of the two compounds into two linear tetrapolyphosphates (P_t/P_n = 1) is complete

(*c*) The hydrolysis of the tetrapolyphosphate proceeds preferentially through formation of two pyrophosphate structures This observation fits with the rate of appearance of secondary acidities evident in Fig 1

It is probable that the relative amounts of structure I and II depend on the preparation and could account for some variation in the behaviour of this material in polycondensation reactions However, a ratio of the order of 1 1 can be expected from the original structure of P_4O_{10} and the observed higher stability of structure II towards hydrolysis

Proton Magnetic Relaxation and Protein Hydration

WE have found that ovalbumin dissolved in water decreases the proton spin–lattice relaxation time T_1 and proton spin–spin relaxation time T_2 and we show that this effect is due to an increase of correlation time of part of the water molecules The correlation time τ can be defined as the mean time of persistence of the angular position of a water molecule and is simply related[1] to the Debye dielectric relaxation time τ_d, $\tau = \tau_d/3$ According to the theory of nuclear magnetic relaxation by Solomon[2], T_1 and T_2 are functions of τ In some cases τ can be expressed as a function of the macroscopic viscosity of the liquid[1], but in the case of protein solutions such an explanation is not possible as was shown by Hennel *et al* [3]

The measurements of T_1 and T_2 of ovalbumin reported here were made at 20° C in magnetic field of 3,288 1 gauss using the Carr–Purcell[4] and Meiboom[5] spin echo techniques Recrystallized ovalbumin from hen's egg-white was used and also some measurements were done on a solution of fresh egg-white Care was taken to ensure that the investigated material was sufficiently free from any paramagnetic ions, which could exert a spurious effect on relaxation To remove such ions, versene (ethylenediamine tetraacetate sodium salt) was added to the protein solution in a dialysis bag and dialysis was performed against distilled water The efficacy of this method was controlled

The results obtained show that the reciprocal of relaxation time increases linearly with the concentration

$$1/T_1 = 1/T_{1w} + k_1 c \qquad (1)$$

$$1/T_2 = 1/T_{2w} + k_2 c \qquad (2)$$

where T_{1w} and T_{2w} are respectively the spin–lattice and spin–spin relaxation times of dialysate, practically equal to values for distilled water exposed to the air $T_{1w} = T_{2w} = 2\ 7$ sec The concentration c is expressed in g of dry protein contained in 1 g of solution The constancy of k_1 and k_2 at different concentration is evident from Table 1

Table 1 VALUES OF k_1 AND k_2 OBTAINED FOR OVALBUMIN AT 20° C AND 14 Mc/s

Concentration ($c \times 10^2$)	Fresh k_1	Fresh k_2	Denatured k_1	Denatured k_2
2 32	2 93	7 15	12 1	89 2
4 69	2 77	5 91	12 0	105 5
5 36	3 06	5 92	12 7	109 5
6·03	2 73	7 30	10 3	87 6
7·30	3 08	7 44	13 6	109 0
8·85	3 33	7 25	12 0	97 8
9 46	3 59	6 66	14 3	104 5
mean	3 07	6 80	12 4	100 4

In order to give an explanation of the obtained behaviour of T_1 and T_2 we assume that the protons present in a sample consist of 3 groups (*A*) Protons situated in water molecules which either do not belong to the solvation layer of any protein molecule or, if they do belong, are bound such a way as to enable them to change their position in relation to the protein molecule The correlation time of water molecules of this type is not affected by the presence of protein and is equal to that in pure water (B) Protons situated in water molecules bound to the protein molecules in a rigid, irrotational[6] way and having, therefore, the same correlation time as the protein molecule itself (C) Protons of the protein molecules having very short T_1 and a rather slow exchange rate[7] with the surrounding water escaped our observation

We have, therefore, to consider only groups A and B If there were no proton exchange between these groups one would observe two separate relaxation times T_a in group A and T_b in group B We assume that such an exchange exists and is so fast that the time of life of a proton in any of the two groups is shorter than T_a or T_b In such a case we shall observe single resultant relaxation time T_1 given by the following equation[8]

$$1/T_1 = p_a/T_{1a} + p_b/T_{1b} \tag{3}$$

where p_a and p_b are the fractions of time spent by a proton in groups A and B respectively They are proportional to the amount of water in each group Let w be the mass of water of group B per 1 g of dry protein Then, at low concentration ($c \ll 1$), we have $p_a = (1 - wc - c)/(1 - c)$ and $p_b = wc/(1 - c)$ and remembering that $T_{1a} = T_{1w}$ we obtain from (3)

$$\frac{1}{T_1} = \frac{1}{T_{1w}} + c\left[\left(\frac{1}{T_{1b}} - \frac{1}{T_{1w}}\right)w - \frac{1}{T_{1w}}\right]$$

This is the linear equation (1) where

$$k_1 = \left(\frac{1}{T_{1b}} - \frac{1}{T_{1w}}\right)w - \frac{1}{T_{1w}} \tag{4}$$

In a similar way we obtain

$$k_2 = \left(\frac{1}{T_{2b}} - \frac{1}{T_{2w}}\right)w - \frac{1}{T_{2w}} \tag{5}$$

Expressing T_{1b} and T_{2b} as functions of τ by means of equations (33) of Solomon's paper[2] and substituting this into equations (4) and (5), we obtain a set of two equations which can easily be solved for w and τ by means of a graphical method (The use of equations (33) which are obtained for isotropic random motion is an approximation only, because the shape of the ovalbumin molecule is ellipsoidal with an axial ratio of about 5 and therefore the motion of the irrotationally bound water molecules cannot be regarded as isotropic) Assuming for k_1 and k_2 the mean values given in Table 1 and the value[9] $b = 1\ 515$ Å for interproton distance in water we obtain for ovalbumin

$$w = 1\ 60 \times 10^{-2}, \qquad \tau = 1\ 03 \times 10^{-8} \text{ sec}$$

For egg-white we find $k_1 = 3\ 62$ and $k_2 = 9\ 13$, which yield

$$w = 1\ 97 \times 10^{-2}, \qquad \tau = 1\ 20 \times 10^{-8} \text{ sec}$$

These values of τ should be comparable with 1/3 of the Debye dielectric relaxation time of the protein According to data given by Edsall[10], $\tau_d/3 = 1\ 6 \times 10^{-8}$ sec for the shorter axis and $\tau_d/3 = 6 \times 10^{-8}$ sec for the longer axis of the ovalbumin molecule In view of the obvious shortcomings of the model this agreement is satisfactory

The amount of water irrotationally bound to the protein is in agreement with the results of Buchanan *et al* [6], who found $0 < w < 0\ 07$ from the dielectric constant of ovalbumin solution at very high frequency

We have found that denaturation of protein by keeping a sealed sample at 100° C for 10 min causes an increase of k_1 and k_2, leading to values $k_1 = 12\ 4$ and $k_2 = 100\ 4$ for ovalbumin, and $k_1 = 10\ 36$ and $k_2 = 61\ 43$ for egg-white These values yield $w = 12\ 3 \times 10^{-2}$ and $\tau = 3\ 25 \times 10^{-8}$ sec for ovalbumin and $w = 8\ 7 \times 10^{-2}$ and $\tau = 2\ 63 \times 10^{-8}$ sec for egg-white, showing that the amount of irrotationally bound water increases as a result of denaturation This may be caused by unfolding of the polypeptide chains and exposing a greater number of polar groups to the surrounding water The increase of irrotationally bound water does not preclude that the whole amount of solvation water decreases

We thank Miss K Caputa for her help in preparing the samples and making measurements

BIOCHEMISTRY

Preparation of a Low Molecular Weight Component with Lactogenic Activity from a Limited Chymotryptic Digest of Ovine Prolactin

THE limited digestion of ovine pituitary lactogenic hormone by chymotrypsin has recently been investigated in this laboratory[1,2] It was found that preparations of prolactin showed lactogenic activity even after 50 per cent digestion with the enzyme Ultracentrifugation investigations revealed that the prolactin core contained a component[3] which had a sedimentation coefficient close to that of the non-treated hormone The digest also contained another protein fraction which sedimented more slowly than the bulk of the material[3] This communication is concerned with the purification and properties of this latter low-molecular-weight component

Prolactin was digested and fractionated by a method essentially the same as that previously described[3] The hormone[4] (3 5 g) was digested to an extent of 50 per cent by incubation with bovine chymotrypsin (Armour Co , Lot No 381092) at 27° C in a *p*H 8 4 buffer containing 0 1 M sodium bicarbonate and 0 01 M *tris* (*tris*(hydroxymethyl)aminomethane) buffer The protein concentration was 1 per cent and the enzyme to substrate ratio was 1 300 The reaction was stopped by carefully adding dilute acetic acid in the cold with continuous stirring until the *p*H of the mixture was 3 The mixture was then dialysed against 0 1 M acetic acid After dialysis the protein was submitted to counter-current distribution in 2-butanol–0 35 per cent dichloroacetic acid[4] The main peak (which had a distribution coefficient of 1 67) was then submitted to chromatography on DEAE (diethylaminoethyl)-cellulose (Schleicher and Schuell Co , Lot No 1196) in *tris* buffer of *p*H 8 2 and ionic strength 0 01 After a prior washing of the column with 0 055 M sodium chloride, two fractions were obtained by elution with 0 1 M sodium chloride (Fraction I) and 0 25 M sodium chloride (Fraction II) Both fractions were again submitted to chromatography on DEAE-cellulose under identical conditions, dialysed and lyophilized

Fig 1 illustrates the results of experiments in which these and other fractions were studied by gel-filtration on 'Sephadex *G*–100' Untreated monomer prolactin (molecular weight 23,000)[3,5] emerged from the column after an elution volume of 50 ml (Fig 1*a*), whereas aggregated

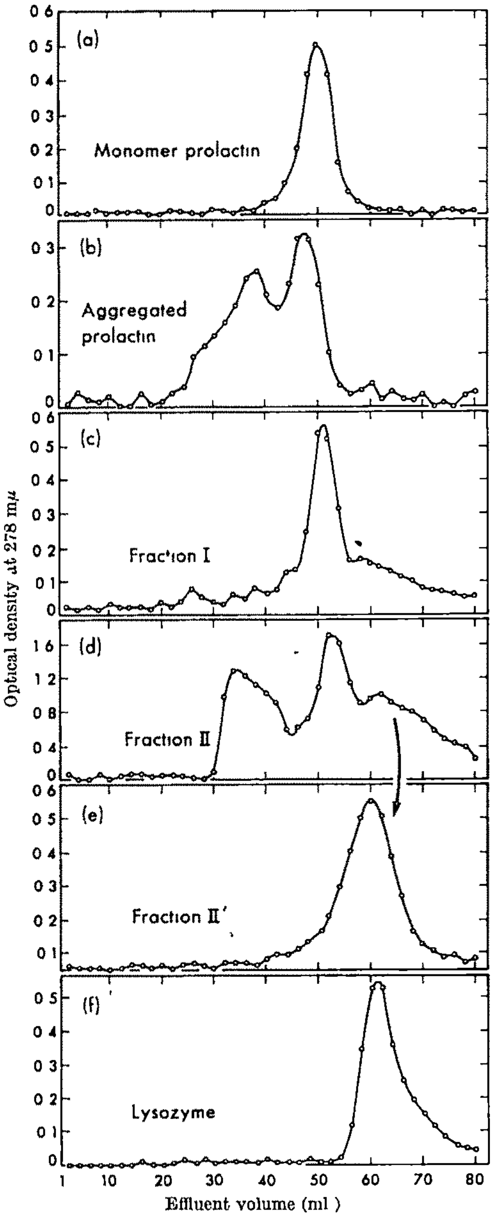

Fig. 1. Gel-filtration on 'Sephadex G-100' in 0.2 M ammonium acetate buffer of pH 8.2 at 20° C. Column size, 107 × 1.6 cm. Fractions of 2 ml. were collected. Flow-rate, 12 ml./h. a, 5.1 mg prolactin monomer (see ref. 3, Fraction A_1), b, 8.6 mg aggregated prolactin (see ref. 3, Fraction C), c, 7.0 mg Fraction I, d, 60.4 mg of Fraction II, e, 10.0 mg of Fraction II′, f, 3.3 mg of egg white lysozyme (Armour Co. Lot 381-187)

prolactin gave rise to multiple components (Fig. 1b). Fraction I, which emerged after the same elution volume as monomer prolactin (Fig. 1c), appeared mainly as a single peak. In contrast, Fraction II appeared to contain three components (Fig. 1d), including one which emerged from the Sephadex column after an elution volume of 60 ml. The latter component (which was designated Fraction II′) was purified by repeatedly submitting it to gel-filtration on 'Sephadex G-100' under the same conditions. Finally, it gave the elution pattern shown in Fig. 1e. In order to obtain a rough estimate of the molecular size of Fraction II′, a sample of egg white lysozyme (molecular weight approximately 14,000) was studied by gel-filtration on 'Sephadex G-100'. Fig. 1f shows that lysozyme was eluted from the column after about the same elution volume as Fraction II′.

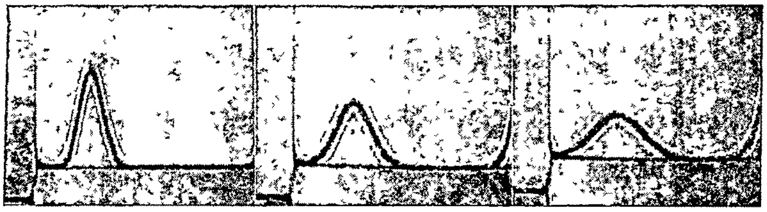

Fig. 2. Sedimentation of Fraction II′ in the ultracentrifuge at 52,640 r.p.m. and 22° C, 13.5 mg protein/ml. solvent, 0.1 M sodium bicarbonate buffer of pH 8.4, sedimentation from left to right, pictures taken at the following intervals after attainment of full speed: 4, 20 and 56 min, artificial boundary-forming cell used

Bioassay of Fraction II′ by means of local crop sac-stimulation in the pigeon[6] showed that it had approximately one half the lactogenic potency of the undegraded prolactin. The result of sedimentation velocity analysis of Fraction II′ in the ultracentrifuge is shown in Fig. 2. In 0.1 M sodium bicarbonate buffer of pH 8.4 the protein sedimented as a single boundary and the sedimentation coefficient ($S_{20,w}$) was found to be 0.88 S, whereas the untreated prolactin monomer has a sedimentation coefficient of 2.18 S under the same conditions[5]. Further investigations on this low molecular weight component possessing lactogenic activity are in progress.

Identities of the Fatty Acids derived from the Polymyxins and Colistin

Hausmann and Craig[1] first demonstrated that the peptide antibiotic polymyxin B was not homogeneous but could be separated by counter-current distribution into two components, polymyxin B1 and polymyxin B2. On hydrolysis, in addition to the amino-acids αγ-diaminobutyric acid, leucine, phenylalanine and threonine, polymyxin B1 gave (+) 6-methyloctanoic acid, which had previously been isolated and characterized by Wilkinson[2]. Polymyxin B2, although containing the same amino-acids gave an optically inactive acid, $C_8H_{16}O_2$, not identical with n-octanoic acid but which was not otherwise characterized.

We have now demonstrated by gas chromatography that the foregoing C_8 and C_9 acids are present, although in different proportions, in the crude fatty acids derived from polymyxin B, polymyxin E and colistin. In each chromatogram the presence of a trace (less than 1 per cent of the total acid) of a third acid was observed, which has been identified tentatively as n-octanoic acid. By counter-current distribution polymyxins B1 and B2 and polymyxins E1 and E2 were obtained. From the acid hydrolyses of polymyxins B1 and E1, (+) 6-methyloctanoic acid was isolated and characterized. Polymyxins B2 and E2 gave optically inactive acids, $C_8H_{16}O_2$, each of which was converted to an optically inactive amide, shown by the melting point, mixed melting point and infra-red spectrum to be identical with the amide of synthetic isooctanoic acid Further proof of identity was obtained by comparison of the gas chromatograms of the methyl esters and paper chromatograms of the hydroxamates of the natural and synthetic acids

Uncoupling Action of Chloramphenicol as a Basis for the Inhibition of Ion Accumulation

SUTCLIFFE[1] has reported that the bacteriostat chloramphenicol at concentrations of 2 g/l effectively stops ion accumulation by tissue slices of red beet root and carrot root Respiration and protoplasmic streaming were unaffected The concentration of chloramphenicol required was much higher than that needed for inhibition of protein synthesis in most bacteria (2,000 versus about 10 μg/ml.), but the necessity for high concentrations in plant and animal systems is commonly observed[2]. Sutcliffe assumed that chloramphenicol was acting as a specific inhibitor of protein synthesis, as in bacteria, and interpreted the results as evidence for a close relationship between the process of protein synthesis and salt accumulation as suggested by Steward[3] Jacoby and Sutcliffe[4] later showed chloramphenicol to inhibit uptake of carbon-14-labelled glutamic acid, glycine and proline by carrot tissue The incorporation of the amino-acids into protein was inhibited in short-term experiments, but glycine and proline incorporation was not affected in long-term (24 h) experiments Net protein synthesis was inhibited

This work of Sutcliffe's could have great theoretical importance, and we have accordingly included chloramphenicol in studies of calcium uptake by isolated mitochondria from etiolated maize shoots The experiments were patterned somewhat after those of Brierley *et al* [5] and Vasington and Murphy[6] About 100 g of 3½-day shoots (*Zea mays*, *WF*9 × *M*14) were ground in a cold mortar with about 250 ml of 0 25 M sucrose + 0 05 M potassium dihydrogen phosphate + 0 005 M ethylenediamine tetraacetic acid (EDTA) adjusted to *p*H 7 5 with *tris*(hydroxymethyl) aminomethane (*tris*) Mitochondria were isolated by centrifugation in the cold between 2,000*g* for 6 min and 12,000*g* for 15 min, and were washed once in the grinding medium and once in 0 25 M sucrose Final suspension was in 0 25 M sucrose The mitochondria were incubated for 10 min at 30° C with the additives listed in Table 1 Ice-cold 0 5 M sucrose was layered below the reaction mixture, and the mitochondria centrifuged through the sucrose The pellet was suspended in water and assayed for radioactivity A complete report on the properties of these mitochondria in absorbing calcium is being prepared For now it can be noted that except for some non-specific adsorption the calcium uptake is dependent on respiratory energy or ATP and is accompanied by phosphate, much as with animal mitochondria[5,6]

Chloramphenicol proves to be an inhibitor of calcium binding by mitochondria at concentrations in excess of 0 4 mg/ml At 1 6 mg/ml , which is in the range of concentration used by Sutcliffe, the extra calcium-binding mediated by substrate is virtually eliminated (Table 1)

However, it was difficult to imagine any appreciable protein synthesis occurring in these isolated mitochondria in the absence of added amino-acids In attempting to find an explanation we noted that the inhibitions of calcium binding were very much like those we had obtained with the uncoupling agent, 2,4-dinitrophenol Although chloramphenicol is not considered to be an uncoupling agent, it was conceivable that at these high concentrations some uncoupling of oxidative phosphorylation might occur

Table 1 INHIBITION OF CALCIUM-BINDING IN MAIZE MITOCHONDRIA BY CHLORAMPHENICOL

Substrate	Chloramphenicol	Total ^{45}Ca (c p m /mg N)	Substrate mediated binding (c p m /mg N)
–	–	26,400	—
+	–	65,900	39,500
+	0 8 mg/ml	45,100	18,700
+	1 6 mg/ml	29,000	2,600

Media contained 625 μmoles sucrose, 6 25 μmoles MgCl$_2$ 0 25 μmoles CaCl$_2$ + ^{45}Ca, 17 μmoles phosphoric acid neutralized with *tris*, 0 1 ml ethanol, 0 6 μmoles NAD, 0 4 μmoles thiamine pyrophosphate, 0 1 μmoles coenzyme *A*, 20 μmoles succinate + 40 μmoles pyruvate (as substrate where indicated), 0 335 mg mitochondrial N, and water to a volume of 2 5 ml The *p*H was adjusted to 7 5 with *tris* Chloramphenicol from Parke, Davis and Co (listed as 1,000 μg/mg) was dissolved in ethanol, and equivalent ethanol was added to controls The ethanol is slightly inhibitory to calcium-binding Specific activity of calcium was 172 c p m /mμ mole

Table 2 UNCOUPLING OF OXIDATIVE PHOSPHORYLATION BY CHLORAMPHENICOL

Chloramphenicol	Uptake O$_2$ (μ atoms)	Uptake PO$_4$ (μmoles)	P/O
None	16 8	29 2	1 74
0 8 mg/ml	14 8	8 8	0 59
1 6 mg/ml	9 1	1 3	0 14

Warburg vessels contained 425 μmoles sucrose, 5 μmoles MgCl$_2$, 40 μmoles succinate, 40 μmoles pyruvate, 42 μmoles phosphate, 100 μmoles KCl, 6 5 μmoles ATP, 0 6 μmoles NAD, 0 4 μmoles thiamine pyrophosphate, 0 1 μmoles coenzyme *A*, 2 5 μmoles EDTA, 100 μmoles glucose, 25 KM units hexokinase, 0 1 ml ethanol, 0 320 mg mitochondrial N, and water to 2 5 ml The *p*H was adjusted to 7 5 with *tris* Reaction was at 30° C for 15 min Chloramphenicol was added in ethanol as in Table 1, with equivalent ethanol in all vessels The ethanol is slightly inhibitory to phosphorylation

Table 2 shows that uncoupling does occur with concentrations of chloramphenicol which inhibit calcium binding. Oxygen uptake is definitely depressed at 1 6 mg/ml In some experiments 0 8 mg/ml chloramphenicol did not affect oxygen consumption, but phosphorylation was always lowered

Uncoupling agents such as dinitrophenol are known to inhibit salt accumulation by plant tissues[7], although the mechanism of inhibition is subject to various interpretations[8] Uncoupling could also reduce an endergonic process such as protein synthesis. Hence the effects of high concentrations of chloramphenicol ascribed to inhibition of protein synthesis might be due to inhibition of ATP synthesis The fact that respiration rates of tissue are not altered by chloramphenicol (or are even accelerated[1]) would be expected over a certain concentration range if the compound were uncoupling oxidative phosphorylation The depression of mitochondrial respiration by 1 6 mg/ml chloramphenicol (Table 2) is the result to be expected from high concentrations of uncoupler, dinitrophenol in excess of 10^{-4} M also depresses oxygen consumption of these mitochondria Calo *et al* [9] have reported variable effects of chloramphenicol on potato tuber tissue respiration, including an inhibition of 25 per cent

These experiments led us to the opinion that the inhibition of salt accumulation in plant tissue by high concentrations of chloramphenicol could be due to uncoupling of oxidative phosphorylation rather than to the action of the compound as a specific inhibitor of protein synthesis

Third Component Participating in the Superprecipitation of 'Natural Actomyosin'

IT has been shown that the superprecipitation of 'natural actomyosin' is subtly controlled by a minute amount of calcium ions[1-3], the superprecipitation is promoted or depressed by the increase or the decrease of calcium ions in the reaction medium respectively This unique action of calcium ions not only affords the basis for the relaxing mechanism of chelating agents[2] as well as physiological relaxing factor[3], but also appears to be closely associated with the link between excitation and contraction[4]

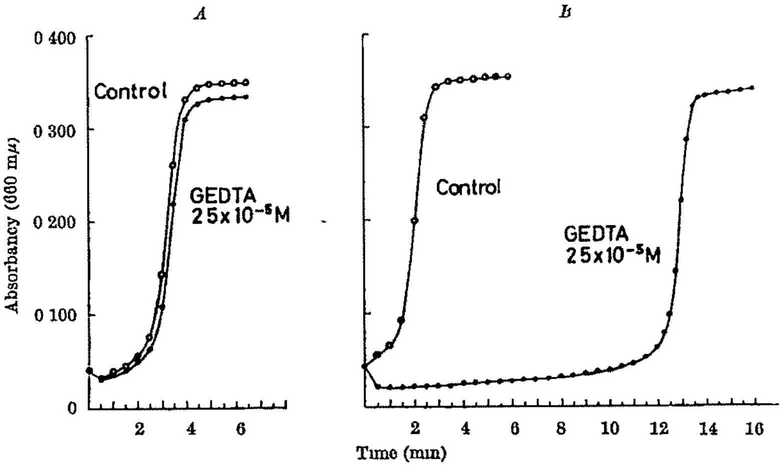

Fig 1 Effect of tropomyosin-like protein on the response of trypsin-treated 'natural actomyosin' to a chelating agent The suspension of 'natural actomyosin', 2 mg/ml , was incubated with trypsin, 10 μg/ml , for 20 min at 20° C After stopping the reaction by trypsin-inhibitor the actomyosin was centrifuged and resuspended for use *A*, The effect of glycoletherdiaminetetraacetic acid (GEDTA) on the trypsin-treated 'natural actomyosin', 0 78 mg/ml , *B*, the effect of GEDTA on the trypsin-treated 'natural actomyosin' plus purified tropomyosin-like protein, 0 08 mg /ml The method for measuring the superprecipitation followed those described in a previous paper (ref 3) For response of untreated 'natural actomyosin' to GEDTA see ref 8

In view of these findings and considerations it is interesting to enquire into a well-known fact[5-8], first noticed by Perry and Gray, that the reconstituted actomyosin is insensitive to the relaxing action of the chelating reagents, in other words, the reconstituted actomyosin lacks an important property of 'natural actomyosin' responsive to calcium ions

Muscle mince was first extracted with Guba-Straub solution according to the routine procedures of actin preparation, then the residue of filtration was exhaustively washed several times at 0° C and finally extracted by water containing 1 mM sodium bicarbonate at about 20° C for 4 h By filtration we obtained a very viscous solution, which was free of myosin and native actin, though it might contain some denatured actin If a fraction of the solution is added to the reaction mixture, the reconstituted actomyosin now behaves like 'natural actomyosin' in its response to calcium ions and chelating agents

Further purification of the active principle was made as follows solid ammonium sulphate was added to the original solution up to 40 per cent saturation Then the supernatant was dialysed against 0 2 mM sodium bicarbonate to eliminate the ammonium sulphate, and the volume of the solution was reduced by evaporating water under vacuum Then the concentrated solution was dialysed against 0 2 mM sodium bicarbonate to reduce its ionic strength below 0 02 Further dialysis against water acidified slightly by carbon dioxide precipitated the essential component After centrifugation the residue was dissolved again by adding a small amount of water by the aid of sodium bicarbonate The protein solution thus obtained has all the properties of tropomyosin found by Bailey[9,10] in every respect· (*a*) the amino-acid composition[9,11], (*b*) the relationship between viscosity and ionic strength[9], (*c*) the sensitivity to trypsin digestion[12]; (*d*) the binding to *F*-actin measured by flow birefringence[13], (*e*) the pattern of ultracentrifuge[10]; the preparation is not yet completely homogeneous but only one peak is appreciable which undoubtedly corresponds to that of tropomyosin In spite of these evidences, usual tropomyosin preparation according to the original method of Bailey[9] is not effective So far, it is not yet decided whether the active principle is the 'native' tropomyosin itself or not

The foregoing facts suggest that the calcium-sensitive nature of 'natural actomyosin' is due to the presence of the active principle in it As noted here, the factor is very sensitive to trypsin digestion Therefore, it is interesting to know whether the nature of trypsin-treated 'natural actomyosin' would become similar to that of reconstituted actomyosin and the addition of the active principle would recover the previous properties of 'natural actomyosin' Fig 1 shows one of the results along this line They are in good accordance with the expectation, indicating that 'natural actomyosin' functionally consists of three protein components—actin, myosin and the factor described here Essentially the same results were obtained with myofibrils

The interaction between actin and myosin in the presence of adenosine triphosphate undoubtedly represents the basic mechanism of muscular contraction However, if we are interested in the physiological contraction of living muscle, where calcium-sensitive property of contractile elements would be of primary importance, the role of the protein factor mentioned here, which resembles tropomyosin in many respects, would be highly evaluated

Details of this communication will be published elsewhere[14].

Cellulase in Tomato Fruits

A CELLULOLYTIC enzyme that reduces the viscosity of sodium carboxymethylcellulose (CMC) solution was found in sodium chloride extracts of ripe tomato fruits using the method of Bell *et al* [1] for determining activity. This is a viscometric method devised for detecting low enzyme-levels by measuring the change in drain time of solutions in Ostwald-Fenske pipettes during a 20-h period

Further extractions were made to compare the activity in the pericarp (wall tissue) and in the locular material (placenta, seeds, jelly and juice) Both salt and non-salt extracts were made The salt extracts were prepared by dissolving 5 g of sodium chloride in 100 g of the blended tissue, holding for an hour at room temperature, and centrifuging out the solids. Non-salt extracts were prepared similarly

In a separate set of salt extractions of the pericarp the activity of an aliquot held in boiling water for 5 min was compared with a non-boiled portion

The salt extracts of the pericarp reduced the drain time during a 20-h period an average of 37 0 per cent, while the non-salt extracts produced essentially no change (Table 1) However, salt had little effect on the extraction from the locular material, which was higher in activity than the pericarp The small difference due to salt with the locular material is probably due to the high juice content of this portion, which would probably contain the enzyme in solution from the breakdown of the cells around the seeds The extracts held in boiling water were found to be inactive

Table 1 PERCENTAGE DECREASE IN DRAIN TIME OF SODIUM CARBOXYMETHYLCELLULOSE DURING A 20-H REACTION PERIOD WITH TOMATO FRUIT EXTRACTS

Extract	Loss in drain time (%)
Pericarp	0 5
Pericarp plus NaCl	37 0
Locular	54 0
Locular plus NaCl	56 7
Pericarp plus NaCl	38 7
Pericarp plus NaCl, boiled	0 0

These results explain why Tracy[2] was unable to detect cellulase in tomato fruits although he did find the enzyme in many portions of the tobacco plant and in several other plants He used expressed sap, which if taken from the pericarp only is shown here to be extremely low in activity In addition, he used a short reaction time of 15 min, which was much too short a period to determine the very low activity

The fact that a cellulolytic enzyme is present in tomato fruits is extremely important in studies on fruit softening since the effect of the cellulolytic enzyme must be assessed as well as the effect of the pectolytic enzymes

Detection of Phosphorothioate Pesticides

THE use of Gibbs's reagent[1] (2 6-dichlor- or 2 6-dibrom-*p*-benzoquinone-4-chlorimine (DBQC)) for locating certain organic thiophosphate pesticides on paper chromatograms was reported by Menn, Erwin and Gordon[2] The reagent forms coloured derivatives with a variety of compounds in aqueous alkaline solution, but the development of a red colour in neutral or slightly acid conditions appears to be quite specific for the P→S group, certainly when linked with solubility of the test substance in petroleum solvents The application of thin-layer chromatography with such a positive identification system offers the possibility of a rapid screening test for these pesticides in toxicological samples

Using a commercially available silica gel/plaster of Paris mixture having a *p*H 6 5 (determined as a 10 per cent suspension in distilled water) only a weak colour reaction was given with quite large quantities of various thiophosphate pesticides on spraying the developed place with 0 5 per cent DBQC in *cyclo*hexane and heating at temperatures up to 120° C However, if hydrochloric acid is added to the mixture used to prepare the plate, to give about *p*H 4, very intense red spots are obtained after spraying and heating to 100° C for 5–10 min, the background remains virtually colourless at this temperature The colour of the spots slowly changes to orange but is then stable for several days, the red colour may be restored by lightly spraying the plate with water

So far as can be ascertained, the reaction is given by all organic phosphorothioates and phosphorodithioates 1 μg produces a very distinct spot with the limit of detection about 0 1–0 2 μg Typical R_F values in benzene-1 2-dichlorethane (1+1) are methyl parathion 0 78, 'Delnav' (2 spots) 0 60 and 0 53, 'Asuntol' 0 37, and 'Diazinon' 0 25

Some variation in the quantity of hydrochloric acid required (which can be determined by titration to *p*H 4) may probably be needed with different silica gels, although a two-fold excess does not seem to cause any adverse effect Normally 10-g silica gel *G* (containing 13 per cent plaster of Paris) is stirred with 10 ml water and 10 ml 0 1 N hydrochloric acid, and the plate (0 75 mm layer) dried at 90°–95° C for 30 min

A concentrated benzene or petroleum ether extract of crops or foodstuffs can usually be applied directly to the plate since interfering substances (which give dark brown or black stains on colour development) remain at or near the origin spot With petroleum ether extracts of stomach contents there is sometimes more interference, but adequate purification can be achieved by partitioning with acetonitrile and spotting the acetonitrile extract.

PHYSIOLOGY

Oxygen Depletion of a Limited Reservoir by Human Conjunctiva

ALTHOUGH the passage of oxygen across the tear-cornea interface is perhaps the best-known example of a direct pathway[1–3] from atmosphere to tissue, other superficial areas can also be demonstrated to receive oxygen in similar manner

An ocular tissue particularly interesting in this respect is the conjunctiva A significant flux across its air-exposed surface might not be unexpected since the maximum oxygen tension of its endogenous[4] vessels can be no more than that of arterial blood, 100 mm mercury, which is considerably less than that of air (155 mm mercury) Also bulbar conjunctiva, especially in close proximity to the cornea, might serve as an oxygen pathway between the atmosphere and the cornea

To measure oxygen flux across the air-conjunctiva interface, a flat surfaced polarographic oxygen electrode (Clark type[3,5], membrane covered) unit, 6 mm in diameter, was placed in direct contact with unanæsthetized human bulbar conjunctiva The polyethylene membrane, fitted over the entire end of the housing served both as an oxygen reservoir and the limiting boundary for a thin layer of *p*H 9 borate buffer solution (0 1 M in potassium chloride) bathing the platinum-reducing electrode This membrane ensures good electrical stability and is the oxygen reservoir of known volume for quantitative analysis By using a 12μ-thick membrane as the oxygen reservoir directly below a 25μ-diameter oxygen cathode, the observed drop in current is almost entirely controlled by the decrease in oxygen tension of the membrane and tissue immediately below the cathode

Current from the electrode was measured with a Beckman model 160 physiological gas analyser and was recorded on a Sanborn model 297 recorder unit The time for 90 per cent response for the entire system was 2 sec

The electrode assembly was allowed to stabilize in air-saturated isotonic saline, maintained at 35° C, for several minutes before each measurement Temperature artefact due to cooling of the electrode while on the conjunctiva was found to be minimal since the polyethylene membrane over the platinum cathode, being small in volume, came quickly to local tissue temperature (35° C) as noted from a thermistor attached to the electrode assembly

Fig 1 shows partial pressure of oxygen in the polyethylene membrane plotted against time while the electrode assembly remained in contact with the conjunctiva, 3 mm distant and 15 mm distant from the edge of the cornea (limbus) This figure provides data from which the rate of oxygen tension decrease in the polyethylene can be calculated These oxygen tension decrease rates can then be converted to ml /sec of oxygen flow from the polyethylene membrane using the Henry's Law constant for oxygen in polyethylene[6], namely, 0 053 c c (S T P)/c c polyethylene atmosphere Because of the relative thinness of the membrane compared with the diameter of the platinum cathode, this flow rate is also the rate at which the conjunctiva withdraws oxygen from its epithelial cells when these cells are in contact with a limited oxygen reservoir, provided by the air-saturated polyethylene membrane

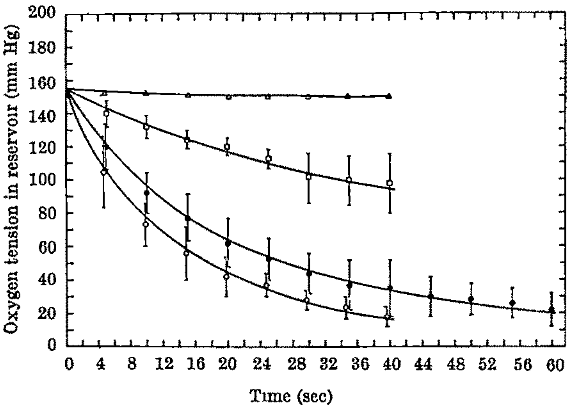

Fig 1 Reservoir mean oxygen tensions plotted against time for bulbar conjunctiva 3 mm (open circles) and 15 mm (closed circles) from cornea For comparison, similar tensions from the forearm (squares) and a synthetic leather surface (triangles) are given

The best estimate of the initial uptake of oxygen by the conjunctiva from this air-saturated membrane at a distance 3 mm from the cornea is 1 9 µl /cm²/h taken from the slope of the appropriate curve at the origin in Fig 1 The range due to scatter of data was 1 6–3 7 µl /cm²/h Rates of uptake at a point 15 mm from the cornea were not found statistically different. For comparison, similar measurements were taken on another air-exposed surface, the forearm—this curve is also given in Fig 1 The initial rate of uptake (at onset of local clamping) for this surface (pO_2 = 155 mm mercury) was 0 55 µl /cm²/h The previously reported value[3] for *in vivo* human cornea was 4 8 µl /cm²/h

Also given in Fig 1 is the control response for the electrode when placed against a moist surface impermeable to oxygen, in this case a soft synthetic leather surface Oxygen consumption of the electrode was in this way found to be negligible

Oxygen diffusion from air into the conjunctiva is too complicated, because of the continuous supply of oxygen by arterial blood and the simultaneous withdrawal by venous blood and tissue consumption, to be described by known solutions of the diffusion equations However, two highly over-simplified models of the air-conjunctiva system permit a very approximate calculation of oxygen flux at the air interface so that some measure of the validity of our experimental data can be obtained

In the first model we assume that for a few seconds after touching the air-saturated polyethylene membrane to the conjunctiva, the surface of the conjunctiva remains at 100 mm mercury, oxygen tension (arterial blood) Diffusion theory then predicts[7] a fall of oxygen tension at the electrode side of the membrane to one-tenth of the initial tension in time equal to 0 94 l^2/D_M, where l is the membrane thickness and D_M is the diffusion coefficient of oxygen in the membrane Fig. 1 gives $D_M = 3{\cdot}8 \times 10^{-8}$ cm²/sec Using this D_M we can calculate the oxygen flux across the membrane-conjunctiva interface for the model we have chosen Unfortunately, this model predicts an infinite flux at zero time, but after 5 sec the predicted flux, from a curve given by Crank[7], is 9 µl /cm²/h, after 20 sec the rate is 3 1 µl /cm²/h and after 30 sec the rate is 1·8 µl /cm²/h These calculated fluxes for the model are in rough agreement with the measured initial flux of 1 9 µl /cm²/h

A second possible model treats the conjunctiva as the surface of a semi-infinite medium with an initial oxygen tension of 100 mm mercury then suddenly exposed at its surface to a constant oxygen tension of 155 mm mercury The oxygen flux per unit area is $\Delta P k_t \sqrt{D_T/\pi t}$, where ΔP is the difference in oxygen tension (55 mm mercury), k is the solubility of oxygen in the tissue, D_T is the diffusion coefficient of oxygen in the tissue, and t is time[7] For this calculation the diffusion coefficient and solubility of oxygen in tissue was assumed to be the same as in 25 per cent protein solution, namely, $D_T = 1 \times 10^{-5}$ cm²/sec and $k_t = 2{\cdot}1 \times 10^{-5}$ ml O_2/ml tissue mm mercury The oxygen flux predicted by this calculation is 7 3 µl /cm²/h at 1 sec, 2 3 µl /cm²/h at 10 sec, and 0 7 µl /cm²/h at 100 sec These values are in reasonable agreement with our experimental value of 1 9 µl /cm²/h for the initial rate of oxygen withdrawal from a limited reservoir

It appears then that we have indeed observed the movement of oxygen into the body across two air-exposed surfaces, the conjunctiva and the skin of the forearm In retrospect our results are not surprising because even in the absence of oxygen utilization the oxygen tension in the body cannot be greater than that of arterial blood 100 mm mercury, and is probably less The gradient between air with an oxygen tension of 155 mm mercury and the body at 100 mm mercury causes a movement of oxygen into all air-exposed surfaces This oxygen is probably not an important source for the body, except in the case of the cornea[3], because it is a minute fraction of the total supply needed At 2 square metres body area and our observed rate of 0 5–2 µl /cm²/h, there is only about 0 01–0 04 l./h moving across the air-skin interface This rate may change at specific locations under pathological conditions of the skin The flux-measuring method we have described may have diagnostic value in these circumstances

HÆMATOLOGY

Limiting Factor in the Assay of Aldolase

Recently, investigations were carried out on the activity of aldolase in blood serum and plasma following whole-body irradiation[1]. Before starting further experiments it seemed necessary to determine whether the aldolase assay to be applied in these investigations can be performed with the same accuracy in blood and plasma. For this purpose the following investigations were carried out. Blood was withdrawn from the heart of guinea pigs by puncture and mixed with sodium oxalate to prevent clotting.

One part of this oxalated blood was hæmolysed by adding saponin; in another part plasma was separated by centrifugation. From these two samples and from the oxalated whole blood 1 : 2, 1 : 4, 1 : 8 serial dilutions were made. In each of these dilutions and in the undiluted (1 : 1) sample, aldolase activity was determined using a Unicam *S.P.*500 spectrophotometer, by the method of Tovarnicky and Voluyskaya[2], as modified by Ananyev and Obuchova[3], being based on similar principles to those used by Y. A. Sibley and A. L. Lehninger[4].

Thus, the blood samples were hæmolysed before the determination of activity of aldolase either by addition of saponin or simply by dilution with distilled water.

The results of these determinations show (Table 1) that the activity of aldolase of the plasma decreases with the degree of dilution. On the other hand, the activity of aldolase of the saponinized blood remains constant, being independent of the degree of dilution.

In oxalated whole blood, the aldolase activity never reached the activity found in diluted samples; even the activity of the 1 : 2 dilution was in some cases lower than the activity of the 1 : 4 and 1 : 8 dilutions.

This latter phenomenon found in non-saponinized oxalated whole blood might have its origin in the fact that the undiluted (1 : 1) and sometimes even the 1 : 2 diluted blood samples were not entirely hæmolysed before the aldolase assay. In some cases the aldolase activity of the 1 : 8 dilutions—saponinized and non-saponinized—show a moderate decrease.

To elucidate the cause of this discrepancy between the degree of dilution and aldolase activity, longer dilution series were made from 1 : 1 to 1 : 32 and 1 : 64, and in one part of these dilution samples aldolase activity was determined without centrifugation and in another after centrifugation at 4,000 r.p.m. for 10 min.

From Tables 2 and 3 it can be seen that activity of aldolase has the same value before and after centrifugation of the diluted samples and that, beginning with the 1 : 16 dilution, the activity of aldolase of all blood samples decreases with the degree of dilution. Consequently the

factor causing the discrepancy between activity of aldolase and degree of dilution is not bound to the stromata but is in the supernatant of the hæmolysed blood, and that from the 1 : 16 dilution this factor causes no discrepancy between activity of aldolase and dilution.

Whether the factor, limiting aldolase activity in whole blood, is the manifestation of enzyme equilibria, or a distinct substance, is to be a subject of further investigation.

These investigations show clearly that: (1) a factor liberated from blood cells by hæmolysis limiting activity of aldolase causes discrepancy between aldolase activity and grade of dilution; (2) the aldolase assay of Tovarnicky and Voluyskaya as modified by Ananyev and Obuchova giving reliable results with blood serum and plasma cannot be applied to whole blood.

Fundamental Function of Ac-globulin and Lipid in Blood Clotting

EVER since the last century when Alexander Schmidt introduced the idea that the clotting of blood can be due to a fibrin ferment which he named thrombin, efforts have been made to understand how this enzyme arises from prothrombin. He already had the view that lipids are concerned, but never knew about Ac-globulin, which is a plasma constituent important for the generation of thrombin activity in association with lipids.

For the purpose of finding out more about the way Ac-globulin and lipids function, work in this laboratory has been directed at the isolation of Ac-globulin from bovine plasma. Even though this endeavour has received constant attention since 1947, we still cannot describe a procedure for obtaining the Ac-globulin as pure as desired for a plasma protein. It is a labile substance. We can, however, achieve 1,000-fold purification in terms of plasma proteins, and by the criteria of immuno-chemistry and the ultracentrifuge (Fig. 1) the product is mainly Ac-globulin and hence very useful for kinetic investigations. Meanwhile thrombin has been purified[1]. A second enzyme was found in prothrombin[2,3] and obtained in pure form[4] (Fig. 1). The substrate, prothrombin, has been available in this laboratory as a purified protein for many years[5] (Fig. 1). With methods of analysis and the strategic proteins (Fig. 1), namely, prothrombin, thrombin, autoprothrombin *C* and Ac-globulin, it was possible to perform some instructive experiments.

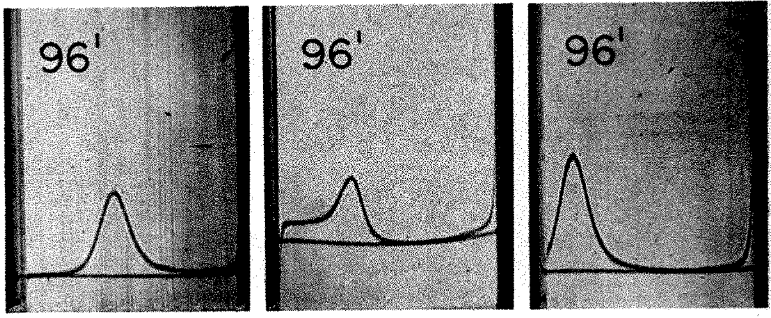

Fig. 1. Ultracentrifuge patterns of purified bovine prothrombin (left), Ac-globulin (centre), and autoprothrombin *C* (right) after 96 min in a 'Spinco' model *E* ultracentrifuge at 50,740 r.p.m. at 20° C. Concentration of protein was 10 mg/ml. We thank Dr. Charles R. Harmison for help in obtaining the ultracentrifuge data

We have come to the conclusion that the conversion of prothrombin to thrombin is fundamentally an autocatalytic process in which either enzyme from prothrombin may be the catalyst. The Ac-globulin alters the substrate specificity of the enzyme so that there are different degradation products of prothrombin when Ac-globulin is present from where it is absent. The lipids are nonspecific in their function and accelerate the complex interactions of the enzyme with substrate.

Considering the experimental facts, the simplest mixture of two proteins was autoprothrombin *C* and prothrombin. The prothrombin became changed to autoprothrombin I (ref. 6). With the same solvent, which contained calcium ions and also Ac-globulin, the prothrombin was converted to thrombin and autoprothrombin III (Fig. 2). Each of these end-products is a substance which we have isolated as a single component. Now when crude cephalin, as commonly prepared[7], was also added to the prothrombin + autoprothrombin *C* + Ac-globulin + calcium ions, the products of the reaction remained the same, but the rate at which they appeared depended on the concentration of lipid used (Fig. 2). Under suitable conditions the yield also increased.

These ideas can be represented by the following equations:

$$\text{prothrombin} \xrightarrow{\substack{\text{calcium ions}\\ \text{autoprothrombin } C}} \text{autoprothrombin I}$$

$$\text{prothrombin} \xrightarrow{\substack{\text{calcium ions}\\ \text{Ac-globulin}\\ \text{autoprothrombin } C}} \begin{array}{c}\text{thrombin}\\ +\\ \text{autoprothrombin III}\end{array}$$

$$\text{prothrombin} \xrightarrow{\substack{\text{calcium ions}\\ \text{Ac-globulin}\\ \text{autoprothrombin } C\\ \text{lipid}}} \begin{array}{c}\text{thrombin}\\ +\\ \text{autoprothrombin III}\\ \text{(rapidly)}\end{array}$$

The quantities of Ac-globulin, autoprothrombin *C*, and lipid in relation to the prothrombin were also varied in all kinds of proportions, including those in which com-

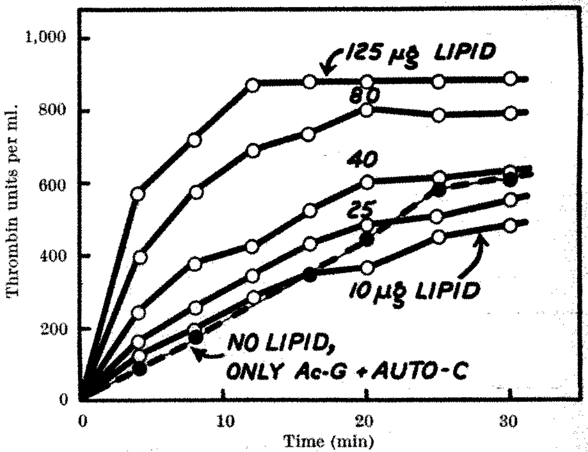

Fig. 2. Activation of purified prothrombin (2,900 U/ml.) at *p*H 7·2 and 28° C with Ac-globulin (80 U/ml.) and autoprothrombin *C* (45 U/ml.) with calcium 0·025 M is represented by lower broken line. No thrombin was formed with autoprothrombin *C* or Ac-globulin alone. The same activation mixture was studied by adding 10, 25, 40, 80 and 125 μg lipid/ml. Assays for prothrombin (ref. 10), thrombin (ref. 10), autoprothrombin *C* (ref. 7) and Ac-globulin (ref. 11) were carried out by previously described methods

plete activation of the substrate occurred in only a few minutes. In a typically slow activation, such as the top curve of Fig. 2, the μg proportions of prothrombin to autoprothrombin *C*, to Ac-globulin and to lipid were respectively 1,500 : 100 : 50 : 125.

Similar to circulating blood, where prothrombin, Ac-globulin, and calcium ions are side-by-side in the plasma medium, they can be together as concentrates in test tubes without changing. The enzyme autoprothrombin *C* does, however, use prothrombin as a substrate and degrades it to autoprothrombin I. The Ac-globulin changes the specificity of the enzyme and prothrombin becomes thrombin + autoprothrombin III instead of autoprothrombin I. The lipid does not change the basic events but alters the rate at which the enzyme does its work. Lipid presumably presents surface interfaces in terms of hydrophilic and hydrophobic structures. Orientation of the protein molecules occurs. The power of the lipid in terms of the rapidity of the reaction is really very impressive. Each component, be it calcium ions, lipid, autoprothrombin *C*, or Ac-globulin, has its purpose and function. What then can be a descriptive term for the function of Ac-globulin? We think the best one introduced thus far was by Ware, Murphy and Seegers[8], who called it a 'co-autocatalyst'. This is what it is in the sense of autoprothrombin *C* coming from prothrombin and catalysing the conversion of prothrombin to thrombin provided Ac-globulin is there. It cannot properly be called a coenzyme since these generally are small molecules and Ac-globulin is a protein.

Landaburu and Seegers[9] stressed their concept of the importance of thrombin in the conversion of prothrombin to thrombin. We have also performed many experiments with that enzyme. The general perspective is the same as with autoprothrombin *C*. First, the simplest combination of thrombin and prothrombin yields autoprothrombin II (with autoprothrombin *C* the product is autoprothrombin I). Then by adding Ac-globulin the enzyme specificity changes and the mixture of prothrombin + calcium ions + thrombin + Ac-globulin yields thrombin and autoprothrombin III. The further addition of lipid does not alter the reaction products, but speeds up their rate of formation and under appropriate conditions may increase the yield. Thus, either enzyme from prothrombin functions in autocatalytic events and Ac-globulin is the co-autocatalyst.

PHARMACOLOGY

Site of the Vascular Reponse to Thermal Injury

THE increase of vascular permeability in response to a number of types of mild injury—including thermal injury—is biphasic, consisting of a transient immediate phase, usually lasting 20–30 min, and a delayed phase which comes to a maximum several hours later[1–3]. The alteration of a vessel wall is demonstrable in animals with carbon particles or a vital dye in the circulating blood: in one case the carbon is deposited between the vascular endothelium and the basement membrane under it; in the other, dye-stained plasma exudes into the surrounding tissues. Majno *et al.*[4,5], applying these methods to the rat cremaster muscle, showed therein that venules and fine capillary vessels were readily distinguishable by their characteristic distribution and size, and that, according to the type of injury, venules alone or both venules and capillaries might be affected. We used Majno's technique to locate the site of vascular change during the response to mild thermal injury. A heated copper disk 9 mm in diameter, as used by Wilhelm and Mason[3] in their investigation of thermal injury to the dorsal skin of the rat trunk, was applied to the scrotal skin.

The permeability responses of the cremasteric vessels were similar to those of the dorsal skin. Since, however, the heat had to penetrate the full thickness of the scrotum, they were less intense for a given disk temperature, and they varied more widely in repeated tests because of the varying thickness of the scrotum, not only from animal to animal, but also as a result of unavoidably differing degrees of stretching of the skin during heating. As in the vessels of the trunk, short exposures of 5–10 sec at 54° C in animals under light anæsthesia induced only the immediate response, involving vessels over the whole of the heated area; whereas longer exposures, 40–60 sec, induced an immediate response, often confined to the edges of the heated area, followed by a delayed response involving vessels over the whole area. Moreover, the longer the application the sooner was the onset of the delayed phase.

Fig. 1 records the biphasic time-course of the response to 54° C for 40 sec in the cremaster muscle. Either pontamine blue (65 mg/kg) or 'Pelikan' ink, 1·0 ml./kg, after partial clearance by centrifugation for 30 min at 8,000*g*, was given intravenously when the thermal lesion had reached the desired age. Each point on the graphs represents the mean response in at least three animals. The exudation of dye was estimated by inspection as a percentage of the maximum blueing obtainable with the disk at 54°. The deposition of carbon in the vessels was determined by examination at a magnification of 18 times, and its amount estimated as the percentage of vessels affected, in terms of the total number of vessels

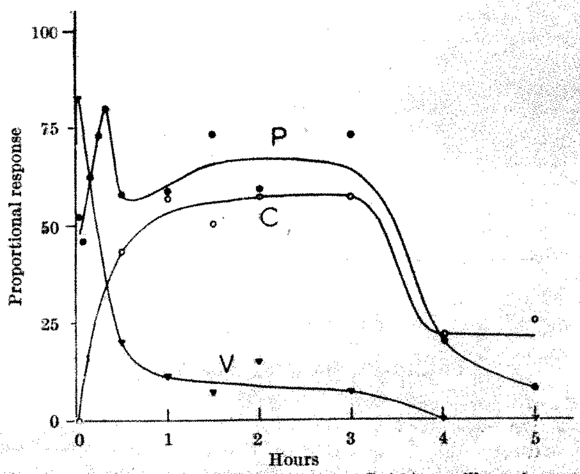

Fig. 1. *P* (●), permeability increase; *C* (○), capillary damage; *V* (▼), venular damage

of each class per unit area revealed by filling all the vessels with an ink–gelatine mixture.

C and *V* in Fig. 1 refer to the deposition of carbon in capillaries and venules respectively. The permeability (*P*) increase is biphasic, and the two phases are strikingly and unequivocally distinguished by the site of vascular damage; in the immediate phase it is venular, in the delayed phase it is capillary. The lag between the venular damage as revealed by carbon and by exudation of dye is noteworthy, and is under investigation by a more detailed analysis of this early phase. A similar but smaller series of tests on the skin of the trunk of mice, in which Prof. L. Kreyberg's strain of hairless (*hrhr*) mice[6] were used to facilitate application of the disk and subsequent observations, gave analogous results—an immediate monophasic response to 54° for 5 sec, associated with venular deposition of carbon and a biphasic response to 54° C for 20 sec. As in the rat, the immediate phase was venular; and in the delayed phase, capillary damage predominated. This clear distinction between venular and capillary damage was first observed by Majno[5], after local application of agents—such as heat, organic solvents and acids—capable of injuring the vascular wall directly. In the lesions induced by each of these agents there was a central area in which capillaries and all other vessels were damaged (direct injury), and around it a ring of venular damage, which he attributed to secondary liberation of endogenous permeability factors, such as histamine (indirect, or mediator-induced injury).

The importance of these observations is two-fold. First, the cremaster technique, and that with hairless mice, offer a means of distinguishing the sites of vascular damage in many forms of injury. We have briefly tested a number of bacterial toxins and living bacteria. All induced a venular followed by a capillary phase, and with some there was in addition a persistent involvement of numerous small veins (not venules) during both phases. In Dr. Majno's laboratory, Dr. Cotran (personal communication) has obtained essentially the same results. Secondly, the demonstration that the major, delayed phase of increased permeability may be associated with purely capillary damage raises doubts about the participation in that phase of some of the endogenous permeability factors proposed as mediators of inflammation[7,8]. In Dr. Majno's hands and ours, histamine, serotonin, bradykinin, globulin *PF* (ref. 8) and lactic acid induce venular changes of short duration. None of these substances, in some instances even when injected repeatedly, induced the capillary change that characterizes the delayed permeability phase of thermal injury. There is clearly at least a *prima facie* case against their participation in this phase of the vascular response to injury.

PATHOLOGY

Thalidomide and Neoplasia

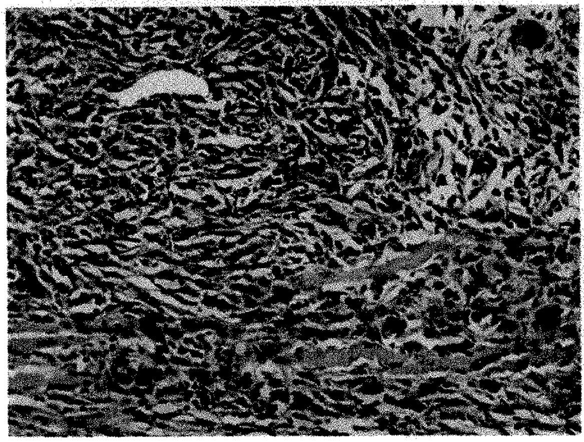

Fig. 1. Sarcoma penetrating voluntary muscle in a mouse injected repeatedly with thalidomide suspended in arachis oil

EARLY in 1962 Prof. Alexander Haddow suggested that we should test thalidomide for carcinogenicity. Accordingly, 20 male mice of the Chester Beatty stock strain were injected subcutaneously in the flank once weekly with 15-mg thalidomide suspended in 0·2 ml. arachis oil. A similar number of mice was injected weekly with arachis oil only and a further group left untreated. Injections of thalidomide were stopped at 57 weeks (total dose of thalidomide = 855 mg), but injections of arachis oil were continued for 90 weeks.

At the time the injections were stopped in the thalidomide-treated mice rapidly growing masses were observed at the injection site in two of the five surviving mice. One of the tumours proved to be a moderately well-differentiated spindle cell sarcoma and the other a more anaplastic sarcoma (Fig. 1). The latter was transplanted subcutaneously into five mice of the same stock strain: the transplants grew progressively in three. The mouse which bore the more anaplastic tumour also had an adenomatous tumour of the lung. No tumours were seen in the 15 mice which died prior to the fifty-seventh week, nor in the remaining three mice which survived beyond that time. One mouse in this group is still alive. No injection-site tumours have arisen in the arachis oil-treated controls, eight of which survived beyond the fifty-seventh week, and three of which are still alive. Two mice in this group were found to have both malignant lymphoma and parenchymal cell hepatomas at post-mortem; such neoplasms occur not infrequently in untreated mice of the same strain. Fifteen of the untreated controls died prior to the development of the first injection-site tumour in the thalidomide-treated group; two with malignant lymphoma. No other neoplasms were seen in these mice, four of which are still alive.

As part of another experiment designed for a different purpose, one male and two female mice were injected subcutaneously daily for seven days each week with 7·5 mg thalidomide in 0·1 ml. arachis oil until they had received a total of 220 injections (total dose of thalidomide = 1·65 g). During the eleventh month one of the females developed a spindle cell sarcoma at the injection site. The remaining two animals developed no tumours and were killed at 12 months.

While we are confident that the three injection-site sarcomas seen in these experiments may reasonably be attributed to thalidomide treatment, we stress that the carcinogenic effect is very weak. Despite the injection of very large doses the incidence of tumours was low and the induction-time long. Furthermore, we point out that the method of administration was not that used when thalidomide was used pharmaceutically. This communication is presented solely because it is felt that our observations may have some basic importance and implications. There is no case for extrapolating the findings to the human situation, and no reason to suspect that thalidomide administered orally in much lower doses, or acquired via the placenta, has any influence on the likelihood of developing neoplastic disease.

There is another cogent reason for doubting the biological significance of the experimental results presented here Certain types of biological activity, in addition to teratogenicity[1], are commonly found in association with carcinogenicity, particularly antimitotic activity, tumour-inhibitory activity, and mutagenicity If thalidomide possesses such activities it does so only in small degree The suggestion that thalidomide may possess tumour-inhibitory activity[2,3] met with negative results in practice Bach *et al* [4] saw no inhibition of two transplantable mouse tumours, and, at the Chester Beatty Institute, we saw no inhibition of growth of the transplantable Walker rat carcinosarcoma 256 in response to thalidomide administered orally or intraperitoneally in repeated large doses Roath *et al* [5,6] observed "an inhibition of some aspects of cellular activity" in leucocyte cultures exposed to thalidomide, but the significance of their findings has been disputed[7] Luers[8] found no evidence that thalidomide causes mutations in *Drosophila*

This investigation was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research Royal Cancer Hospital) from the Medical Research Council, the British Empire Cancer Campaign, the Tobacco Research Council, and the National Cancer Institute of the National Institutes of Health, U S Public Health Service

IMMUNOLOGY

Template Requirement in the Primary Antibody Response

In most considerations of the role of the antigen in antibody formation the assumption is made that a template is either formed or activated A template, by definition, is a system whereby many replicas are produced The need for a template is based largely on the secondary response in which large quantities of antibodies are produced in response to small quantities of antigen over a long period of time This, indeed, does appear to require a template I wish to question whether the information available indicates that primary antibody formation requires a template

In earlier papers[1-3], we have discussed quantitative aspects of the antibody response In one of these papers[2] a graph was constructed relating antigen dosage to antibody response for diphtheria toxoid and poliovirus in man The secondary responses showed much more antibody formed than antigen administered 10^{-12} moles of diphtheria toxoid/kg produced about 10^{-6} moles of antitoxin/l while 10^{-14} moles of poliovirus/kg produced about 10^{-12} moles of antibody/l The primary responses were in marked contrast to this 10^{-9} moles/kg of toxoid produced about 10^{-9} moles of antitoxin/l and 10^{-14} moles/kg of poliovirus produced about 10^{-14} moles of antibody/l

It is true that serum protein antigens do not appear to follow this pattern For example, rabbits given a primary intravenous injection of 8×10^{-8} moles/kg of bovine-γ-globulin produced 6×10^{-6} moles/l. of antibody[4] Similarly, chickens given 2×10^{-7} moles/kg of bovine or human-γ-globulin produced respectively 2×10^{-5} and 1×10^{-5} moles/l of antibody while 4×10^{-7} moles/kg of bovine or human albumin produced 2×10^{-5} and 1×10^{-5} moles/l of antibody[5] In all these cases the amount of antibody formed is approximately two orders of magnitude greater than the amount of antigen given It should be stressed, however, that serum proteins given as single injections are always used in considerably larger doses than are antigens of microbial origin This raises the question as to whether a primary response is being measured or a combination of primary and secondary responses The latter concept gains some support from the fact that a secondary response to bovine-γ-globulin is only about twice the primary response[4]

While such calculations cannot be precise, it is difficult to believe that two antigens used in very different amounts, of different origins and of different antigenicity should both produce in the order of 1 molecule of antibody for 1 molecule of antigen as a purely accidental phenomenon If on primary immunization this is true, then a template need not be postulated While direct use of the antigen for a single moulding of antibody is attractive, this appears inconsistent with present-day knowledge of protein synthesis mediated by RNA The clonal selection theory sees antigen as playing a purely stimulatory part in the replication of lymphoid cells already producing the specific antibody It is difficult to see how this would be consistent with a 1 1 ratio of antigen and antibody

Active Immunization of a Human Being against Cobra (*Naja naja*) Venom

Because of the complexity of venom proteins and their great local and systemic effects, active immunization has been confined to animals utilized in the production of commercial antivenins In work recorded here, the feasibility of a safe and practical method of immunization of man against snakebite has been explored

Parrish and Pollard[1] found that immunity against the effect of snakebite did not exist among 14 human subjects, each of whom had been bitten twice or more by crotalid snakes However, the development of a persistent immunity might not be anticipated in this group because envenomation occurred from 2-year to 14-year intervals, and the members of the group were also treated with antivenins following snakebite The first observation of active immunization against snakebite was reported by Haast and Wiener[2] A subject (human) was given repeated injections of crude cobra venom over a period of 2 5 years A maximal injection of 40 mg of venom was tolerated, this quantity of venom is lethal in the absence of immunity Immunological tests were not performed with the serum or globulin to determine the degree of protection afforded by these injections, but the 40 mg immunizing dose of venom he tolerated is significant

Wiener[3] described in one human subject the titre rise and persistence effected by repeated injections of Australian tiger snake venom This subject survived the bite of a snake of this species with little difficulty subsequent to his immunization

In this laboratory, in an attempt to measure the development of neutralizing antibodies, a human subject

Table 1 IMMUNIZATION SCHEDULE OF HUMAN SUBJECT

Days	0	6	10	14	20	27	33	40	47
Dose	0 050 mg	0 100 mg	0 150 mg	0 500 mg	0 250 mg	0 350 mg	0 500 mg	0 750 mg	1 mg
Days	54	61	72	86	100	30-day rest	138	130	145
Dose	2 mg	4 mg	6 mg	8 mg	10 mg	30 day rest	6 mg	8 mg	10 mg

was given 17 injections containing increasing amounts of Indian cobra (*Naja naja*) venom. Venom solutions were passed through a 'Millipore' filter and then added to an equal volume of a 4 per cent sodium alginate adjuvant (Colab Laboratories, Box 66, Chicago Heights, Illinois) The 17 injections were given over a period of five months (Table 1) 10 ml of blood was withdrawn from the subject after the fourth, seventh and tenth injections 500 ml of blood was withdrawn after the eleventh injection and 1 litre after the seventeenth Globulins were separated from serum by ammonium sulphate precipitation, and the antivenin titre was determined by neutralization of *Naja naja* venom in 18–20 g Swiss mice Identical neutralization tests were conducted by a commercial laboratory (Table 2)

Table 2 DRIED GLOBULIN RESTORED TO FLUIDITY 1 G PLUS 8 0 C C DILUENT FOR ANTIVENIN NO 349207

Venom, LD_{50}	168 mg (1 LD_{50} = 0 00595 mg)
Neutralization	Globulin versus venon
	1 c c of human globulin solution as prepared here neutralizes 36 LD_{50} cobra venom (0 244 mg neut /c c)

The results of this work show a development of active immunization against cobra venom 1 ml of the globulin solution neutralized 30 mouse LD_{50}'s (0 244 mg venom) Since it required 100 ml of whole blood to produce 1 g of the crude globulin, it is estimated on a blood volume basis that 40 g are present in the subject's circulation This circulating globulin alone, therefore, should neutralize a dose of 100 mg cobra venom This calculation does not take into account the extravascular globulins present in the area of envenomation, which themselves are capable of venom neutralization

The subject receiving cobra venom was under observation by a physician Periodic blood and blood chemistry examinations were conducted to determine possible pathological conditions arising from the injections Examination of the subject during and after the injections indicated the absence of pathological response to the venom except for local swelling and pain, which persisted from one to three days in the area of injection For a 2-week period after the fifteenth injection of venom the subject's blood pressure was elevated slightly

The potential advantages of active immunization of man against envenomation have been recognized for many years The presence of locally necrotizing enzymes in some venoms still presents a formidable obstacle However, in venoms with little or no local toxicity it appears that man may be safely immunized

I thank Wyeth Laboratories, Marietta, Pennsylvania, for their assistance in neutralization tests described here

RADIOBIOLOGY

Cæsium-137 Content of Fresh-water Fish in Finland

INVESTIGATIONS of the diets of the Finnish Lapps[1,2] have revealed that fish is the second important source of radiocæsium for several Lapp groups Unexpectedly, high radiocæsium values, especially in pike, were obtained in the first analyses of Lapland fish[2] Therefore it seems important to carry out substantial research on the hydrospheric chains of fall-out nuclides both in Lapland and other parts of Finland In the following the results of our fish analyses up to the present time are briefly reported These include analyses of cæsium-137 and potassium in 23 samples of fish from the Finnish Lapland and a number of samples from 2 lakes in southern Finland

The fish were caught during the period 1961–63 The main part of the samples, 21 in number, were taken from Lake Inari (28° E , 69° N), one sample from the Kemi river (24° E , 66° N) and one from the Nakkala river (24° E , 69° N) The samples taken for comparison are from southern Finland, from the Pyhajarvi (23° E , 61° N) and Nasijarvi (23° E , 62° N) lakes, and were caught in the spring of 1963 In addition, we have analysed 3 fish samples from the Varanger fjord on the Arctic Ocean (30° E , 70° N), caught in May 1962 At the fishing place the fish were weighed and their lengths were measured After this the entrails and heads were removed and the fish were soaked in formalin so as to preserve them Later a scale sample was taken for age determination Also, the 'teeth' of the gill arches of the whitefish were counted in order to determine the subspecies The fresh weight of the samples was usually 1 5–2 kg The fish were dried at 100°–110° C They were ground and their activity was measured in a cylindrical plastic container, the diameter of which was the same as that of the crystal on which it was placed The volume of the container was 0 5 l

The 512-channel pulse-height analyser was made by the Finnish Cable Works, and Harshaw's 3 in × 5 in sodium iodide crystal was used The calibration of the system for the determinations of cæsium-137 was made with a Radiochemical Centre standard solution *CDR* 4 2/11/60 For the potassium calibration Merck's potassium chloride was used In the cæsium-137 range (0 60–0 72 MeV) the sensitivity was 13 9 c p m /nc. and in the potassium range (1 38–1·56 MeV) 7 38 c p m /g potassium The corresponding backgrounds were in the cæsium-137 range 2 90 c p m and in the potassium range 1 49 c p m The potassium correction in the cæsium-137 range was 0 26 c p m /g potassium The lead shield used for the reduction of the background count was 12 cm thick The system was calibrated for the density 1 0 and the correction for the variation of the density was 3–4 5 per cent Each sample was measured for 1 h and in the cæsium-137 determinations the value of 2σ varied as follows When the cæsium-137 content was 0 1 nc /kg (fresh weight) $2\sigma = \pm$ 14 per cent and when the cæsium-137 content was 5 0 nc /kg (fresh weight) $2\sigma = \pm 1$ per cent In the potassium determination 2σ was about ± 6 per cent The results of the measurements are presented in Table 1 The samples taken in January 1962 were analysed at Lund[2]

An examination of the Lapland samples reveals that the cæsium-137 content of various fish species vary rather much (0 6–6 nc /kg) If the samples are divided into two groups on the basis of their activity using 2 nc /kg as the dividing line it will be noted that the fish containing more than 2 nc /kg are fish of prey and that the low activity group includes only grayling and whitefish, which feed on insects, insect larvæ and plankton

Several sub-species of whitefish are distinguished in Lake Inari, three species of which were analysed separately (Table 2) Considerable inconsistency prevails regarding the Latin names of these sub-species Those used in Table 2 were given by Jarvi[3] For the *C fera* Jur f *inarensis* Jarvi the name *C pidschian* Gmelin is also used The samples were taken in July 1962

The results show a tendency in the direction of diminishing activity when the feed changes from plankton to bottom animals In general the activity of the whitefish unambiguously seems to have risen during the year 1962 An analysis of the activity of pike and trout also supports this fact

If the Lapland samples are compared with Arctic Ocean samples (Table 3) there is a clear difference between the cæsium-137 values The activity of the Arctic Ocean samples is only about 1/20th of that of the Lapland samples It also seems that the cæsium-137 values of the fish in southern Finland are somewhat lower than in Lapland So far as the samples from southern Finland are concerned, however, comparison is difficult for the reason that the Nasijarvi and Pyhajarvi samples represent quite different levels of activity For example, if the cæsium-137 activities of fish of the same species, burbot and pike, are compared in the two lakes, 8–10 times higher activities are observed in the Nasijarvi samples These two lakes are reported to represent two different lake types, Nasijarvi being a humus type of lake, Pyhajarvi a low-humus 'rich' lake Humic acids are weak cation exchangers and some limnologists consider them to represent an important dietary item for the zooplankton It thus seems that the fish get the main part of their radiocæsium through their food intake even though a smaller part may come directly from the water through the mechanism in the gills which regulates the salt balance Also, it seems plausible that the high cæsium-137 contents found in the fish of prey in the two lakes of humus-type is due to a food chain humus—zooplankton—small fish—big fish

Age determinations were made of 22 fish samples dealt with here No clear correlation between the age and the cæsium-137 content of fish of the same species could be observed Fresh-water fish have been analysed since 1961 for radionuclides in Sweden too, with results of a similar type[4]

The results presented here will form a basis for the planning of more comprehensive studies of the cæsium-137 content of fish in which attempts will be made to clarify the enrichment chains of cæsium-137 from the water through plankton and bottom animals to the fish

Limnological advice by Dr Reino Ryhanen and aid in acquiring some of the fish samples by Mr Jorma Toivonen are gratefully acknowledged The age determinations were made by Mr Lauri Peippo

This investigation was supported by a grant from the Finnish Atomic Energy Commission and by scholarships to one of us (E H) from the Suomalainen Tiedeakatemia and the Niilo Helander Foundation

BIOLOGY

Liberation of Extracellular Nitrogen by Two Nitrogen-fixing Blue-green Algae

In a previous communication[1] it has been shown that certain nitrogen-fixing blue-green algae isolated from marine environments liberate appreciable quantities of fixed nitrogen into the medium during healthy growth. This feature has been observed for many blue-green algae by other workers[2-4] and investigations on the production of extracellular nitrogen have also been carried out[5-7] This communication provides information on the relationship between growth and liberation of extracellular nitrogen by the two nitrogen-fixing species *Nostoc entophytum* and *Calothrix scopulorum*, and on the nature of the extracellular products

The strains utilized were those used in previous investigations[1,8] and were available in pure culture The correlation between growth and liberation of extracellular material was investigated by growing the algae in nitrogen-free medium under conditions which, apart from a more vigorous air supply (3 5 c c /flask/sec) and higher temperature (mean 27° C), were similar to those described elsewhere[1]. The rate of production of extracellular nitrogen was studied over a 24-day period, the nitrogen liberated being determined at 4-day intervals by collecting the contents of triplicate flasks and obtaining nitrogen[9] and dry weight[1] data Alga and medium were separated through a bacteria-proof filter and the algal filaments gently washed twice with distilled water, the washings being added to the filtrate The results obtained are presented in Fig 1 It is evident that vigorous fixation of nitrogen by both species occurred during the experimental periods and microscopic examination revealed no unhealthy filaments Thus, the extracellular nitrogen did not appear to be due to cell autolysis Both algae show a high initial exudation rate, which with *Calothrix* decreases with age up to the 12–16-day stage and thereafter markedly increases The pattern of exudation by *Calothrix* is very similar to that recorded for *Anabaena*[5], and while *Nostoc* showed no latter increase in extracellular nitrogen it is possible that had the experiment been continued further an increase would have occurred

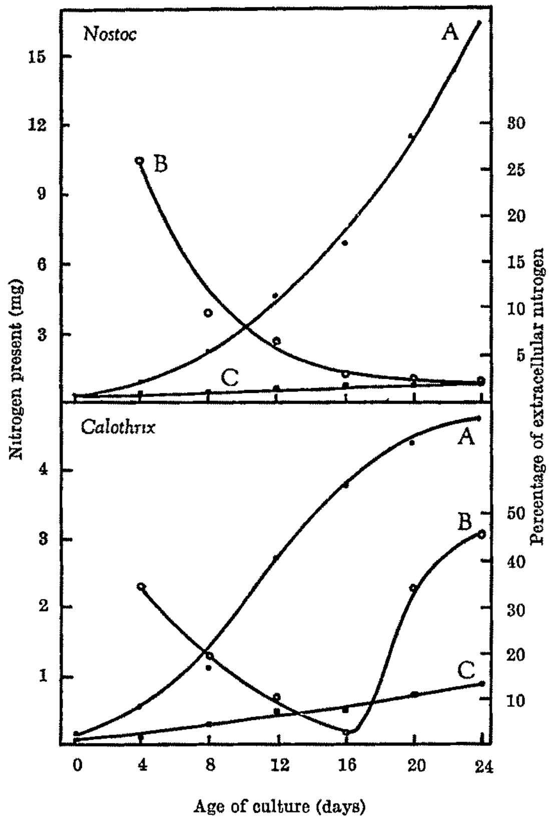

Fig 1 Liberation of extracellular nitrogen by *Nostoc* and *Calothrix* *A* represents total nitrogen fixed, *B* represents nitrogen liberated during preceding 4-day periods as percentage of total nitrogen fixed during same period, *C* represents mean extracellular nitrogen

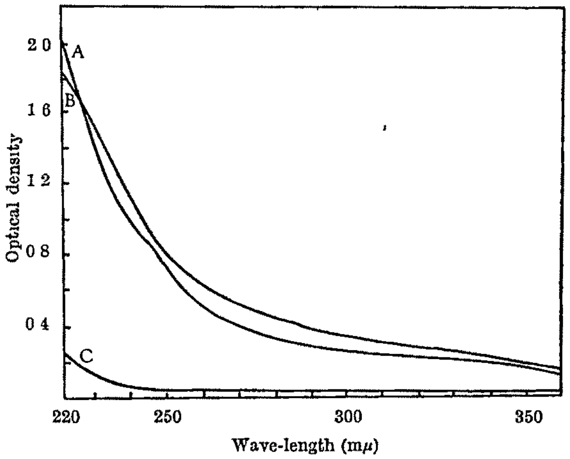

Fig 2 Light absorption by *Nostoc* filtrate (*A*), *Calothrix* filtrate (*B*), artificial sea-water (*C*)

It has been recorded by other workers[10] that filtrates from several species of algae, none of which was blue-green alga, show high absorption of ultra-violet light and thus for comparison data were obtained on light-absorption in the range 220–680 mμ by filtrates of the algae under investigation Readings were carried out on a Unicam *S P* 500 spectrophotometer (220–360 mμ) and Unicam *S P* 600 spectrophotometer (360–680 mμ). It was not possible with the particular instrument used to record absorption below 220 mμ The results obtained on absorption in the range 220–360 mμ by 24-day-old filtrates are presented in Fig 2 These show that maximum absorption both by the artificial sea-water medium used and by the algal filtrates occurs in the ultra-violet region and that absorption by the filtrates is much greater than by the sea-water medium alone The absorption spectra obtained are very similar to those of natural sea water and filtrates of various other algae[10], suggesting that the shape of the absorption curves of natural sea water may be due partly to the extracellular products of algae and other micro-organisms In the region 360–680 mμ absorption by the filtrates decreased with increase in wavelength while an overall increase in absorption occurred as the cultures aged

Analyses of medium from 24-day-old cultures for the presence of amino-acids were carried out, as it has been shown that these substances form an appreciable part of the total nitrogen liberated by blue-green algae, where they are present in the free state[5,6] and in the form of peptides[5] After desalting the filtrates[11] they were concentrated *in vacuo* and applied before and after hydrolysis to two-dimensional paper chromatograms and the amino-acids estimated semiquantitatively[12] The results showed that, for *Calothrix*, alanine, threonine and leucine were present in largest quantity together with traces of aspartic acid, glutamic acid, phenyl-alanine, serine, glycine and proline After hydrolysis the same amino-acids and also valine were present but in very much higher quantities, alanine, glutamic acid and leucine being most abundant In *Nostoc* filtrates the basic amino-acids and threonine were most abundant while there were traces of aspartic acid, glutamic acid, serine, alanine and glycine In the combined form these amino-acids increased substantially in quantity, glutamic acid, threonine and the basic amino-acids being most abundant, while leucine and valine, which were not present in the free state, were detected There appeared to be little qualitative or quantitative correspondence between the amino-acids liberated by the two species, and there is evidence[7] that the production of extracellular nitrogen may vary according to the conditions of growth

These results suggest that the nitrogenous substances liberated by the foregoing algae may be of biological importance in Nature for it has been shown that many micro-organisms utilize amino-acids as nitrogen sources while others require amino-nitrogen for growth Droop[13] has shown, for example, that the cryptomonad *Hemiselmis virescens*, from the same locality of seashore as the algae under consideration, is dependent on amino-nitrogen for growth There is also evidence[14] that the extracellular nitrogenous compounds of blue-green algae may be important as chelating agents in fresh-water, and it is probable, therefore, that in marine environments the extracellular products of marine blue-green algae exert a similar function

Seedling Inoculation with *Ustilago nuda* (Jens.) Rostr.

The vacuum method of seedling inoculation with chlamydospores of *Ustilago nuda* already described[1] was the first non-floral method to give high infection percentages in barley This method has the disadvantage, where large numbers of seedlings are concerned, that the coleoptiles must be cut individually by hand before being placed under vacuum in the chlamydospore suspension It has now been found possible to infect barley seedlings without the tedious and time-consuming necessity of cutting the coleoptiles.

When barley seeds were germinated at about 20° C until the coleoptiles of the seedlings, which were then usually 2–3 cm in length, were burst by the emerging first leaf and were then inoculated by the vacuum method but without cutting of the coleoptiles, a low percentage of smutted plants resulted (6 per cent) as compared with that of plants from seedlings the coleoptiles of which were cut when they reached a length of about 1 cm and were then vacuum inoculated (57 per cent) An experiment to induce natural breaking of the coleoptiles at a shorter length by exposing the seeds to light during germination resulted in the coleoptiles being burst through at various lengths all shorter than the controls in total darkness which were still unburst at 5 cm

A mercury vapour lamp suspended 15 in above the water agar plates on which barley seed was germinating at 17° C, the seed having first been allowed to absorb water at 3° C for five days, resulted in the first leaf bursting the coleoptiles when the latter were only about 1 cm in length When such seedlings were placed under a vacuum of 25 in of mercury in a chlamydospore suspension for three successive periods of 1 min, 79 per cent smutted plants resulted

This limited trial indicates that equally good results may be expected from the inoculation of uncut seedlings germinated in the foregoing manner as were previously obtained by the original method

Immobilization of Elephant Seals using Succinylcholine Chloride

Biologists of the Australian National Antarctic Research Expeditions have been investigating the ecology and physiology of the southern elephant seal, *Mirounga leonina* Linn, at Macquarie Island for many years[1] Present work requires the animals to be handled for a variety of procedures, but their large size (mature cows 2½ m long and 500 kg in weight, mature bulls 5 m long and 3,000 kg in weight) makes physical restraint of any but small pups impossible

Muscular relaxants have long been used for restraining wild animals in captivity[2,3] and extension of these techniques to the field has facilitated studies of a variety of land mammals[4] One pinniped, the California sea lion, *Zalophus californianus* Lesson, has been immobilized in captivity[3] This communication reports the extensive use of succinylcholine chloride for immobilizing elephant seals, *Mirounga leonina* Linn, the establishment of reliable dose rates, and the elephant seal's tolerance to high dosages

Intramuscular injections of a concentrated (200 mg/ml) solution of succinylcholine chloride were administered by means of an extension syringe This comprised a 20-ml veterinary syringe screwed to a light metal tube, 3 ft long, down which a rod passed to actuate the plunger The injection was made on undisturbed animals just anterior and lateral to the base of the tail The straight-line length from nose to tail of each animal was estimated by eye and converted to a total body-weight by reference to a regression curve of Laws[5] Exact dose rates were then calculated Subsequent weighing and measuring of immobilized seals generally confirmed Laws's figures

In 42 attempts, we have successfully immobilized 31 seals up to 4 5 m long and weighing an estimated 2,500 kg. Nine of the eleven failures to immobilize occurred with large adult male seals, the blubber of which may not have been penetrated by the needle. Dose rates of 0 5 mg/kg (0 23 mg/lb) and 1 mg/kg (0 45 mg/lb), while sometimes effective, were not as reliable as 2 mg/kg (0 91 mg/lb) This rate greatly exceeds doses used on domestic animals apart from pigs, which require a similar quantity for complete relaxation[6], and is 4–8 times the effective dose rate for the California sea lion[3]

Paralysis often occurred in less than 0 5 min and usually within 1 min of injection Its duration varied from a few sec to 45 min and no ill-effects were observed after the animals recovered Muscle paralysis followed a definite sequence which was similar to that observed in other animals[4,6] Facial muscles were affected first, followed by those of the neck and hind flippers; then the fore flippers and finally the body musculature relaxed Paralysis of the diaphragm may also have been induced, since apnœa appeared to last for periods up to 10 min, sometimes to the extent of cyanosis of the tongue Hyperventilation of similar duration preceded muscle recovery, the sequence of which occurred in the reverse order to that of paralysis

Immobilized elephant seals have been subjected to a number of procedures to which, judging by the absence of distress or after-effects due to handling and other treatment, they seem ideally suited We have taken skin biopsies and blood samples, injected vital stains, and measured, weighed and transported seals to enclosures for observation The immobilization technique should greatly facilitate certain surgical procedures on suitably anæsthetized animals and the administration of hormones and drugs can also be tried

The ease with which elephant seals of almost any size can be restrained by injections of succinylcholine chloride has considerably extended their use as field and experimental animals for biological research There is good reason for supposing that other Antarctic phocids would react to this drug similarly, thereby allowing them to be more readily examined Improvement of the technique against the very largest elephant seals is proceeding

Evolution of the Giraffe

THE mode of evolution in the giraffe has been a favourite subject for discussion Darwin[1] wrote " it has been supposed that all the parts must have been simultaneously modified, and it has been argued that, on the principle of natural selection, this is scarcely possible but it cannot be denied that an animal might have its neck, or head, or tongue, or forelimbs elongated a very little without any corresponding modification in other parts of the body". Graham Cannon[2], very properly I consider, rejects this, concluding "It is this idea of co-ordinated variation that is, to my mind, the central core of the whole problem of evolution".

Doubts on the extent of the survival value conferred by ability to reach high twigs arise when it is considered, as Graham Cannon (p 139) pointed out, that the male giraffe is some 2 ft taller than the female and thus by natural selection the females would tend, disastrously, to be eliminated in times of drought, Himmelfarb[3] similarly objects that the young would tend to be eliminated likewise

Schreider[4] discusses the value, to certain human races living in hot climates, of dolichomorphism as an aid in achieving heat loss So also to the giraffes, living as they do in hot climates, their dolichomorphic structure will serve a similar purpose to young or old, male or female continuously and not merely in times of drought, while at the same time enabling them to achieve that size and tallness which confers greater ability to evade, or defend against. predators and to reach a source of food otherwise unavailable to them Which factor has been of greatest evolutionary value is uncertain Darwin[5] wrote in this connexion "The preservation of each species can rarely be determined by any one advantage, but by the union of all, great and small"

To the best of my knowledge and belief, no one has ever suggested that dolichomorphic races of man evolved by elongation of first one part then another, and evolution by pattern mutation is very much the more probable.

Monolayer Tissue Culture on 'Cellophane' Squares

'CELLOPHANE' has for some years been recognized as a material on which monolayers of many cell types can be grown[1] When a sheet of 'Cellophane' is so covered with cells it can be cut up into small pieces which are suitable for a number of uses

For example, they can be distributed into tissue culture tubes and used as stationary or roller cultures for virus isolation and titration They can be frozen and stored, probably indefinitely, in a liquid nitrogen refrigerator and remain ready for use on reconstitution

The types of cell grown and stored satisfactorily so far include the following (*a*) primary cultures of human embryo kidney and bovine testis, (*b*) secondary cultures of monkey kidney and human amnion , (*c*) continuous cell lines, that is, HeLa (2 strains), *MK*2, *HEp*2 and *L* cells

No unsatisfactory cells have so far been encountered, but it has been found that too dense a cell sheet may detach from the 'Cellophane' when it is cut

Ordinary thin 'Cellophane' sheet sold in rolls for wrapping purposes is used It is cut into rectangles about 7 cm × 3 cm which will fit inside a 2-oz. 'medical flat' screw-cap bottle. Each piece is cleaned and sterilized by immersion in ether followed by ethanol and sterile distilled water after which it is introduced as a roll into a bottle with sterile precautions and kept moist with a little sterile buffered saline

Each bottle is inoculated with about 8 ml of cell suspension of a density suitable for culture on glass, and care is taken to ensure that the 'Cellophane' is completely wetted and submerged before incubation To inspect the growth the bottle is gently tilted so that the 'Cellophane' sticks to the glass whereupon the bottle can be turned and examined microscopically

When the monolayer is nearly confluent the medium is poured off and the 'Cellophane' extracted with fine pointed forceps and placed, cells uppermost, on a little medium in a Petri dish

It is then cut into strips about 7 mm wide and these are cut into squares and washed off the scissors into a bottle of medium One sheet yields about 40 squares If not required immediately they may be kept satisfactorily in 10 ml of medium in a screw-cap bottle and remain usable about as long as ordinary tube cultures

Squares can be stored, probably indefinitely, in a liquid nitrogen refrigerator such as the Linde *LNR–25–B* 20 or more can be put into 1 ml of dimethyl sulphoxide freezing solution and frozen slowly in the manner described previously[2,3] Reconstitution is by rapid thawing at 37° C, and the squares are then distributed as required without washing The medium should have a low bicarbonate content to prevent temporary excessive alkalinity[4] Freezing and thawing do not seem to cause detachment of the cells. When detachment has occurred it has been the result of the manipulations If the damage is not too great the cells usually grow over the 'Cellophane' again within a day or two

Squares put into 1–2 ml medium in tubes which are incubated vertically behave like comparable monolayers on glass Inspection of a monolayer is easily performed by sloping the tube then giving it a twist so that the square sticks to the glass. A variety of virus strains have been grown in this way, for example, vaccinia, herpes simplex, poliovirus, influenza, and respiratory syncytial virus, and the cytopathic change (CPE) was in each case indistinguishable from that seen in monolayers on glass. Sub-culture can be made by transfer of the square or the medium or both. Infectivity titrations and neutralization tests are performed with economy in glassware by the addition of squares to the tubes containing the virus or virus–serum mixtures.

In roller tubes the squares stick to the glass within the area traversed by the medium and seem to suffer no deterioration. Human embryo kidney cells gave CPE at the same times as parallel tube cultures when inoculated with several strains of common cold viruses, including wild type strains as well as *FEB* and *HGP*.

The number of cells per square is approximately ⅛ that of a normal monolayer. This has the disadvantage of presenting fewer cells for examination than in a monolayer on glass and it gives a lower virus yield. However, an advantage was that the medium needed to be changed only once a week instead of daily.

Preservation of monolayer fragments offers a number of possibilities which have so far been only partially explored. It is a means of preserving viable fragments of cell sheets in prolonged experiments.

Reconstitution is so quickly carried out that monolayers are available on demand and this might enable them to be used for the isolation of labile viruses from clinical material. It could be especially useful in rendering available monolayers of cells of unusual sorts or kinds required infrequently.

CYTOLOGY

Asynapsis of the Salivary Chromosomes of Hybrids between *Anopheles punctipennis* and *Anopheles freeborni*

Burgess[1] showed by crossing *Anopheles punctipennis* with *A. freeborni* that these two species were more closely related to each other than was generally thought. In crossing experiments between these two species when *A. punctipennis* was the female, 8·3–15·2 per cent of the eggs hatched, from which only one adult emerged, although it died because it could not free its tarsi from the pupal case. In the reciprocal cross with *A. freeborni* females, 2·2–25·1 per cent of the eggs hatched, but showed high mortality in the first and second instars and only one larva reached fourth instar.

While making salivary gland chromosome maps of *A. freeborni* and *A. punctipennis*, we found that there were considerable similarities in the banding patterns of certain regions of the chromosomes. The ends of the chromosomal arms of the two species were very similar. Of particular significance was the great similarity of the banding pattern in the left arm of chromosome III of *A. freeborni*[2] to that of *A. punctipennis*; the similarity was so close that the map of III–*L* for one species fit that of the other species. Therefore, the chromosomes of the hybrids would be of special interest.

Reciprocal crosses using induced copulation[3] were made between the two species. Nine chromosomal smears[4] were made of the resulting fourth instar larvæ for each of the two possible crosses. We were surprised to find little or no chromosomal synapsis in either cross. Fig. 1 shows the typical configuration of the chromosomal complement of the hybrid between the *A. freeborni* females × *A. punctipennis* males. Even in the left arm of chromosome III little or no synapsis occurred although the similarity of the banding pattern can be followed in both the maternal and paternal chromosomes. Of interest was the close proximity of all five arms to each other in all squash preparations although they are not synapsed.

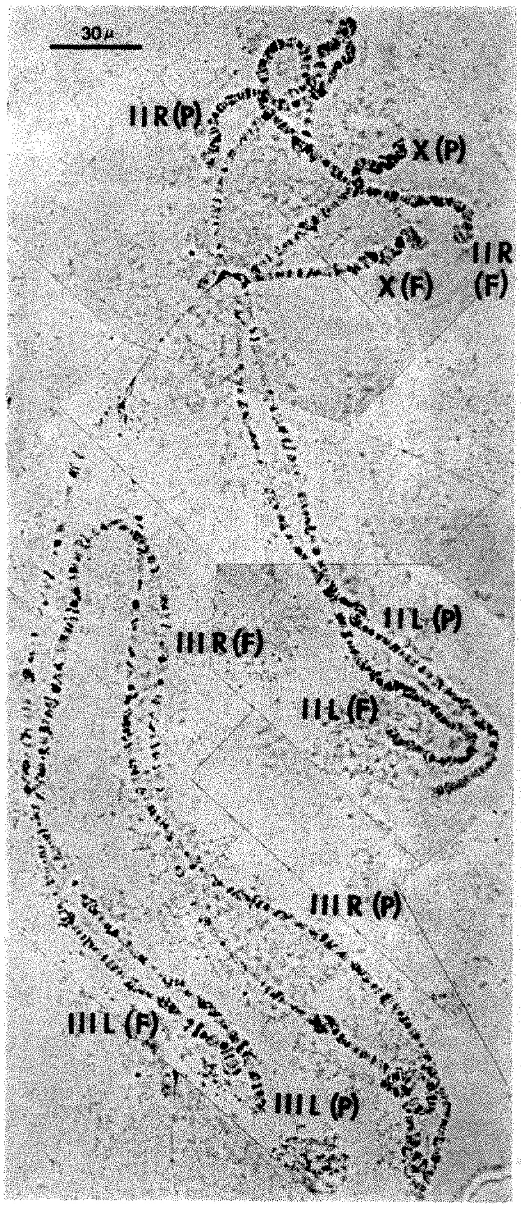

Fig. 1. Salivary chromosomes of hybrid of *A. freeborni* ♀ × *A. punctipennis* ♂. Chromosome arms are designated *X*, II-*R*, II-*L*, III-*R*, III-*L*. *P* = *A. punctipennis*; *F* = *A. freeborni*. (Composite photo)

Each of the hybrid chromosomes seemed almost as wide as a normal synapsed pair of chromosomes in *A. punctipennis* or *A. freeborni*. We thought it possible that the hybrids might be allotetraploids. This could explain the width and the proximity of the chromosomes of the two species. Allotetraploidy would seem to be ruled out by the observation of the normal diploid number of six chromosomes in the brain of a hybrid fourth instar larva. Probably the close approximation of the unsynapsed chromosomes is a manifestation of the general phenomenon of somatic pairing.

The asynapsis and easy identification of the chromosomes from both species offer a sure method of identification of naturally occurring hybrids between these two species.

This work was supported in part by grant *E*–3486 of the U.S. Public Health Service.

ENTOMOLOGY

Oviposition in Relation to the Accumulation of Bloodthirsty Black Flies (*Simulium* (*Gnus*) *arcticum* Mall. (Diptera)) prior to a Damaging Outbreak

THE black fly *S. arcticum* is notorious for its destructive outbreaks along the downstream sections of the North and South branches of the Saskatchewan River in Canada. Outbreaks during 1944–46, inclusive, killed an estimated 800 animals[1]. Since 1948, annual treatments of the rivers with DDT larvicide have generally prevented spring outbreaks.

The adults of *S. arcticum* emerge daily from May until October in numbers affected by various conditions in the preceding adult and larval environments. Usually only the earliest adults in the season appear suddenly in overwhelming numbers; throughout the remainder of the summer the adults continue to emerge from the river and to attack animals, but in relatively uniform small numbers from day to day. On only two occasions were late summer attacks heavy enough to kill cattle. The sudden appearance of excessive numbers of flies during spring outbreaks was attributed to the simultaneous emergence of large numbers of black fly adults[1]. However, observations during periods of emergence did not support the 'mass emergence' theory, and an additional possibility, the accumulation of newly emerged adults awaiting suitable attack weather, was considered. This theory, too, no longer seems adequate because attacks have been observed over a wide range of weather conditions including high winds. Evidence here presented indicates that, in an autogenous generation, the accumulation of nulliparous females in the gravid state, awaiting precise environmental conditions for oviposition, is an important prerequisite to a mass attack.

During 1960–62 attacking populations of black flies at Saskatoon near the Saskatchewan River were sampled and their oviposition experiences determined. Adults were collected at half-hourly intervals, as they came to bite horses, throughout several diel cycles. Examination of these flies for follicular relics showed that more than 99 per cent of the adults in the initial mass outbreaks in the springs of 1961 and 1962 had already oviposited prior to seeking their first blood meal. In August, 1960, only 65 per cent of the flies coming to take blood had previously oviposited. Thus *S. arcticum* is apparently a 'facultative blood sucker', a category, according to Rubtzov[2], which includes most blood-sucking species. In May and June when the larval environment of *S. arcticum* apparently favours the accumulation of large nutrient reserves, the emerging females can be autogenous and thus not require a blood meal until they have deposited their first batch of eggs. When the larval environment is less favourable (as in August) a large proportion of the emerging females are anautogenous and require a blood meal before they can develop their first batch of eggs.

Despite larviciding, the 1962 spring outbreak was severe enough to kill cattle. Judging by the sizes of the follicular relics of flies attacking animals at this time, most had laid eggs only a few hours previously. These occurrences of autogeny and mass attack in a single generation support this theory that the emerging black flies accumulate in a gravid condition in the vicinity of the emergence site until weather favourable for oviposition occurs. These black flies oviposit while in flight over the surface of a river during calm mild evenings[3]. Only after depositing their first batch of eggs do they venture forth in search of a blood meal. The range of meteorological conditions suitable for oviposition appears to be much narrower than that for blood seeking and thus they are more likely to accumulate in the gravid state than in the post-gravid state. In the laboratory, fully gravid females will retain their eggs for many days in the absence of an environment suitable for oviposition.

The observations recorded here also show that the flies often mate and feed on nectar before they approach an animal for a blood meal. However, these two apparent essentials are often dispensed with, leaving oviposition as the only main adult event that must occur before autogenous flies are free to search for a blood meal.

This theory is potentially important in behaviour investigations of all 'mass-outbreak species' the females of which are autogenous in the first ovarian cycle, because it suggests that there is a greater urgency to investigate the meteorological requirements for oviposition than for blood feeding if this basis for predicting outbreaks is sought. Until now, behaviour investigations of these black flies have been concerned only with meteorological requirements for blood feeding.

I thank Michael Ivanochko for sorting and dissecting the large number of black flies used in this investigation.

VIROLOGY

Use of a Combined Complement-fixing Antigen to detect Arthropod-borne Viral Infection

IN an area where several arthropod-borne viruses are active, the examination by complement fixation of acute and convalescent human sera to detect possible infection with local agents may be tedious and time consuming. Sometimes the convalescent sera alone are screened and those that react with one or more antigens are then paired with the acute specimen and retested.

To avoid screening large numbers of convalescent sera against several antigens, preparatory to testing the paired sera, I have used in the initial test a combined group *B* arthropod-borne viral antigen, as follows.

The five group *B* viruses identified in South India, dengue types 1, 2 and 4, Japanese encephalitis and West Nile, are combined after treatment of infected baby mouse brains with sucrose and acetone according to the method of Clarke and Casals[1]. Antigens are diluted so as to give 2–4 units of each, based on box titrations with homologous hyperimmune mouse sera, in the final combination. Antigen serum mixtures are held overnight at 4° C prior to the addition of the hæmolytic system. One unit represents that dilution of antigen giving nearly complete fixation of two units of complement with the highest dilution of serum[2].

In complement-fixation tests with known hyperimmune mouse sera, the reaction of the combined antigen with each serum has resembled that using the homologous antigen alone One such test, a box titration using individual antigens as well as the combination, is presented in Table 1 In other tests marked serological crossing has been noted, particularly within the dengue and Japanese encephalitis–West Nile groups The heterologous reaction has never, however, exceeded the homologous

Table 1. COMPLEMENT FIXATION USING INDIVIDUAL AND COMBINED ANTIGENS AGAINST KNOWN IMMUNE SERA

Antigen		Hyperimmune mouse serum				
Type	Initial dilution in combination	Dengue 1	Dengue 2	Dengue 4	Japanese encephalitis	West Nile
Group *B* combination		128/256*	128/256	256/256	512/512	64/512
Dengue 1	1 8	128/128	—	—	—	—
Dengue 2	1 16	—	128/256	—	—	—
Dengue 4	1 8	—	--	256/128	—	--
Japanese encephalitis	1 16	—	—	—	512/512	—
West Nile	1 16	—	—	—	—	128/512

* Reciprocal of serum titre/reciprocal of antigen titre

Using the combined preparation, with antigens diluted as indicated in Table 1, 36 convalescent sera were tested from patients with dengue-like illnesses or pyrexias of unknown origin that did not yield viruses Twenty of these combined with the grouped antigen to fix complement at a dilution of 1 8 or greater When these 20 sera were paired with the acute samples and retested against the individual group *B* antigens, a four-fold or greater rise to one or more viruses was demonstrated for 11 patients With the other nine patients complement-fixing antibody-levels in both specimens were equivalent

The 16 convalescent sera not reacting with the combined antigen were next tested against the individual antigens In no case was complement fixed at a dilution greater than 1 4

The combined antigen thus indicated in every instance those sera which would react with the individual antigens Conversely, no false positive reactions were noted In work now under way, the principle of a combined antigen is being applied to several additional, unrelated Vellore agents

PSYCHOLOGY

Saline Preference Curve for Mice: Lack of Relationship to Pigmentation

Two lines of investigation have led to the experiment described here A large body of data has been gathered on the preference behaviour of animals presented with a choice between saline solutions of various concentrations and distilled water Most species studied seemed to manifest a preference for saline solutions of low (hypotonic) concentration and an aversion to solutions of higher (hypertonic) concentration[1,2] A much less thoroughly investigated problem arises from the recurrent but apparently little-known observation that darkly pigmented animals have greater taste sensitivity than their lightly pigmented conspecifics

Hoshishima *et al* [3] have recently examined this phenomenon in mice presented with various taste substances These workers report no saline preference and report unusually high discrimination (aversion) thresholds for all strains used In addition, their black strains appeared to have higher thresholds than their white strains, while the hypothesis that pigmented animals are more sensitive to taste would predict a difference in the opposite direction Since the statistical techniques used required extremely large differences in order to reach significance, initial preferences may have been overlooked and only the more pronounced aversions taken into account If a saline preference of dark mice did exist, and was maintained at higher concentrations than that of white mice, and only aversion thresholds were observed, it might be erroneously concluded that the discrimination threshold of black mice was the higher

Because melanocyte-stimulating hormone has adrenocorticotrophic properties[4], and because of possible structural relationships between melatonin and Farrell's 'adrenoglomerulotropic' factor[5], one purpose of this experiment was to ascertain more conclusively whether pigmentation may be specifically related to sodium chloride appetite It was also deemed important to determine whether or not mice manifest a saline preference and to re-evaluate the saline discrimination threshold since no adequate investigation of these phenomena in mice has been reported to our knowledge

Thirty-six male mice, 5–6 weeks of age and of approximately equal body-weight, were used The mice were obtained from the Roscoe B Jackson Laboratory and comprised six separate strains with six mice per strain There were three albino strains (*SJL/J*, 129/*J*, *CAF/J*) and three black strains ($B_6D_2F_1$, B_6AF_1, *C57BL/6J*) Pairs of animals of each strain were placed in wire mesh cages on to which were symmetrically attached two inverted 50-ml graduated test-tubes with standard curved metal drinking spouts Mice were maintained in a temperature controlled room and fed Purina laboratory chow *ad lib*

Following a 10-day period during which distilled water was presented in both tubes, a saline solution was substituted for the water in one of the tubes Five concentrations (0 003, 0 010, 0 033, 0 100, and 0 333 molar) were presented in an ascending order of concentration with the concentration increased on each Friday of five successive weeks Twice weekly (Tuesdays and Fridays) readings were taken, tubes were emptied and refilled with fresh

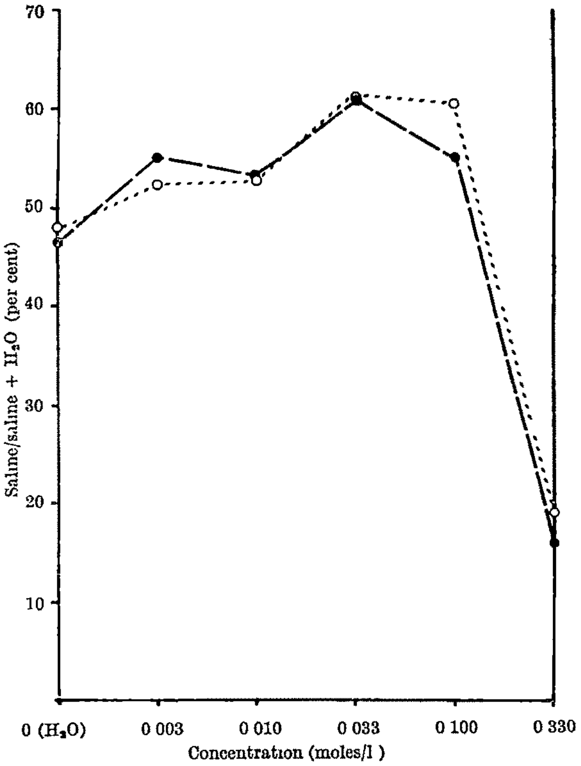

Fig 1 Saline preference-aversion functions for black and white mice Relative preferences computed in terms of saline ingestion as percentage of total fluid intake ——, Black, - - -, white

solutions, drinking nozzles were exchanged randomly, and relative positions of saline and water were reversed It was hoped that this relatively long period between position alternations would allow more stable preference behaviour to develop

Fig 1 shows the preference-aversion functions of the black and white strains Differences between black and white animals did not approach significance at any saline concentration There were no observable differences between individual strains However, because a few animals temporarily escaped and on recapture could be identified with certainty for pigment but not strain, statistical analyses of strain differences were not performed

At each concentration, t tests were applied to the differences between amounts of water and saline ingested using the pooled data of all animals The discrimination (preference) threshold falls between 0.01 and 0.033 molar, which is within the range of that found for the rat[1] Significant saline preferences were obtained at concentrations of 0.033 molar ($P < 0.01$) and 0.10 molar ($P < 0.05$) A significant saline aversion occurred at 0.333 molar ($P < 0.001$) These 'P' values represent two-tailed tests

These results indicate (*a*) that mice produce a typical saline preference-aversion function when offered saline solutions of different concentration in addition to distilled water, (*b*) the suggested relationship between pigmentation and taste sensitivity or appetite for sodium chloride was not confirmed

This work was supported in part by grant *MY* 2949 to Prof Neal E Miller from the National Institute of Mental Health, U S Public Health Service, and done during the first author's tenure as U S Public Health Service pre-doctoral fellow, and second author's tenure as U S Public Health Service post-doctoral fellow

Heart Rate during Auditory Vigilance Performance

THE work recorded here is the first in a series of experiments designed to investigate the relationship between cardiac activity and the performance of monotonous tasks and tasks involving high rates of information processing

Since drowsiness is commonly reported by subjects of vigilance experiments it is to be expected that this would be reflected in a decrease in heart rate during a vigil, and it is possible that this decline will be related systematically to the decrease in the number of signals detected correctly during different periods of the vigil Furthermore, Lacey and Lacey[1] have suggested that variability in resting heart rate may be indicative of the quality of performance shown by subjects engaged on perceptual-motor tasks They differentiate between those subjects who show high variability (labiles) and those who show low variability (stabiles) and suggest that each group is liable to show consistent modes of responding and to commit specific types of errors Although they have not used vigilance tasks in their investigations the implication seems to be that the more variable the heart rate at rest the more are commissive errors likely to occur in vigilance situations

In the present work, electro-cardiographic recordings were taken from eight subjects (mean age 21.5 years) in an auditory vigilance situation The task consisted of a tape-recording of a series of digits, 1–9 inclusive, recorded in random order at the rate of 1/sec The signal to be detected consisted of a series of three successive odd digits which were all different There were 24 such signals during the 60-min task, six occurring at random intervals during each 15-min period Subjects responded by pressing a key which was attached to an event recorder whenever they considered a signal to have occurred Heart rate measures (the number of R waves/min) were taken during the following periods (1) a 20-min pre-task resting period, (2) the first 7 min of the task, (3) the ninth, twelfth, fifteenth . . fifty-first min of the task, (4) the last 8 min of the task, (5) during a 10-min post-task resting period

The mean heart rate for each subject for each 15-min period was divided by his mean heart rate during the pre-task resting period These 'working-resting' ratios were then transformed into Z-scores for the group Performance scores (the number of correct detections) for each 15-min period were also transformed into Z-scores for the group These data are given in Table 1, from which it will be seen that heart rate and performance both decline during the course of the vigil

Table 1 RELATIONSHIP BETWEEN HEART RATE AND VIGILANCE PERFORMANCE DURING THE COURSE OF THE EXPERIMENT

15-min periods	Z scores	
	Performance	Heart rate
1	+ 1.60	+ 1.40
2	0.00	+ 0.20
3	− 0.50	− 0.30
4	− 1.00	− 1.30

The results seem to indicate a systematic relationship between heart rate and vigilance performance It is not possible, however, to interpret this easily in terms of decreasing activation during the course of the vigil, since for this to be the case the beginning of the task should be accompanied by a substantial increase in heart rate In the case of only one subject was this observed, and all mean working-resting ratios were less than unity

Lacey[2] considers that a deceleration in heart rate is associated with the uptake of information It seems possible that the deceleration observed in this work may be due to increased attempts by subjects to take up information from the task and the environment as the vigil proceeded

Subjects were ranked in terms of variability of resting heart rate, in terms of total error score (that is, errors of omission and of commission combined), and in terms of errors of commission only The rank-order correlation between heart rate variability and total error score is given by $\tau = 0.69$ ($h = 2.02$, $P < 0.01$), and between heart rate variability and commissive error score by $\tau = 0.42$ (non-significant)

It is difficult on the basis of the results of this work, in which only eight subjects participated, to draw any reliable conclusions about individual differences in detection ability and their prediction, but the significant correlation between cardiac lability and total error score suggests that heart rate variability may be some prediction of vigilance performance, although it seems unlikely that it will efficiently predict commissive errors in performance

This work is supported by a grant from the Medical Research Council

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, December 9

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London, W C 1), at 5 30 p m —Dr I Hacking "On the Foundations of Statistics"

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Measurements at Very Low Frequencies with particular reference to Noise" opened by Dr J L Douce, Mr H Sutcliffe and Prof J C West

Institution of Electrical Engineers, Science and General Division (at Savoy Place, London, W C 2), at 5 30 p m —Dr F Fallside and Mr M R Patel "Effect of a Back E M F Non-linearity on Responses of a Second-order Position Control System", Dr F Fallside and Dr J O C Ezeilo "Application of the Second Method of Lyapunov to the Stability of Certain Position Control Systems containing a Back-E M F Non-linearity"

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 6 p m —"The Pitcairn People" (colour films)

Tuesday, December 10

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N W 1), at 5 p m —Scientific Papers

Royal Society of Arts Commonwealth Section (at John Adam Street, Adelphi, London, W C 2), at 5 15 p m —Dr T W Tinsley "The Ecological Approach to Pest and Disease Problems of Cacao in West Africa" (Inaugural John Curtis Lecture)

Institution of Civil Engineers (at Great George Street, Westminster, London, S W 1), at 5 30 p m —Mr H R Boyce "Swansea Docks—Entrance Works"

Institution of Electrical Engineers, Science and General Division (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Materials for Hall Effect Devices" opened by Mr R P Chasmar

Institution of the Rubber Industry, London Section (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W 1), at 5 30 p m —Mr M S Evans "Mould Design" 7 p m —Panel Discussion on "Accelerators"

Royal Society of Medicine, Library (Scientific Research) Section (at 1 Wimpole Street, London, W 1), at 5 30 p m —Dr Gordon Wolstenholme "Ethiopia in a Modern Africa"

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Prof J N Davidson "Recent Developments Among the Nucleic Acids" (Sixteenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

Institution of Chemical Engineers, South-Eastern Branch (joint meeting with the Chemical Engineering Group of the Society of Chemical Industry, at 14 Belgrave Square, London, S W 1), at 6 p m —Mr T W G Rowe "High Vacuum"

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Mr G V. Cleare "Factors Affecting the Performance of High-Speed Tracklayers"

Wednesday, December 11

Geological Society of London (at Burlington House, Piccadilly, London, W 1), at 5 p m —Dr E P Saggerson and Mr B H Baker "Post-Jurassic Erosion Surfaces in Eastern Kenya and their Deformation in Relation to Rift Structure", Dr R Nicholson "The Structure and Metamorphism of the Mantling Karagwe–Ankolean Sediments of the Ntungamo Gneiss Dome and their Time-Relation to the Development of the Dome"

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W C 1), at 5 30 p m —Prof M Francon (Professeur à la Faculté des Sciences de Paris et à l'Institut d'Optique) "Polarizing Interference Microscopes"

Institution of Mechanical Engineers, Hydraulic Plant and Machinery Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Mr J E Austin and Mr J R Palfrey "Product Mixing During Serial Flow in Pipelines"

Royal Institute of Chemistry, London Section (at Shell Mex House, Strand, London, W C 2), at 6 p m —Annual General Meeting, followed by a film show

Royal Society of Arts (at John Adam Street, Adelphi London, W C 2), at 6 p m —Sir Ifor Evans "Education in London" (Edmund Rich Memorial Lecture)

Institute of Information Scientists (at the Swedenborg Society Hall, 20 Bloomsbury Way, London, W C 1), at 6 15 p m —Mr A G Readett "The Organization and Administration of a Technical Translation Department"

Society of Chemical Industry, Food Group—Nutrition Panel (at 14 Belgrave Square, London, S W 1), at 6 15 p m —Prof Sir Alister Hardy "Can We Get More Food from the Sea?"

Institute of Metals (joint meeting with the London Branch of the Institute of British Foundrymen, at the National Liberal Club, Whitehall Place, London, S W 1), at 7 p m —Mr G Swinyard "Quality in Copper Based Castings"

Oil and Colour Chemists' Association (at the Institution of Electrical Engineers, Savoy Place, London, W C 2), at 7 p m —Prof R N Haszeldine "Inorganic Polymers—Fact or Fiction"

Society of Instrument Technology, Automation Section (at Manson House, 26 Portland Place, London, W 1), at 7 p m —Prof M W Thring and Mr D F Nettell "Domestic Automation"

Society of Chemical Industry, Plastics and Polymer Group (joint meeting with the Liverpool Section, at the Donnan Laboratories, University of Liverpool), at 7 30 p m —Dr R N Haward "Additives in Thermoplastics"

Wednesday, December 11—Thursday, December 12

Institution of Chemical Engineers (at Church House, Great Smith Street, London, S W 1), at 9 30 a m daily—Symposium on "Productivity in Research"

Thursday, December 12

Institution of Electrical Engineers, Electronics Division (joint meeting with the Medical and Biological Electronics Group of the British Institution of Radio Engineers, in the Department of Physiology, University College, Gower Street, London, W C 1) at 10 30 a m and 2 30 p m —Discussion on "The Brain"

Institution of Civil Engineers, Traffic Engineering Group (at Great George Street, Westminster, London, S W 1), at 5 30 p m —Informal Discussion on "Practical Applications of Traffic Theories" introduced by Mr J G Wardrop

Institution of Electrical Engineers, Power Division (at Savoy Place, London, W C 2), at 5 30 p m —Discussion on "Performance of Large A C Motors for Industrial Drives" opened by Mr B Barker, Mr A B D Reed, Mr D D Stephen and Mr A C G Witts, also Mr D D Stephen "Connecting Large Machines to Power Systems"

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr P Brookes "Chemical Aspects of Mutation" (Seventeenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)*

Chemical Society (at the Royal Institution, Albemarle Street, London W 1) at 6 p m —Prof J S Anderson, F R S "Some Contemporary Problems of Solid State Chemistry" (Liversidge Lecture)

Institution of Mechanical Engineers, Internal Combustion Engines Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "Residual Fuels—Is Their Use Justified ?"

Society for Analytical Chemistry, Biological Methods Group (at "The Feathers", Tudor Street, London, E C 4), at 6 30 p m —Nineteenth Annual General Meeting, followed by a Discussion Meeting on "The Detection of Substances with Teratogenic Properties" opened by Mr K E V Spencer

Society of Chemical Industry, Microbiology Group (joint meeting with the Birmingham Section, at Haworth Building, The University, Birmingham), at 6 30 p m —Dr K Burton "Structure and Action of Deoxyribonucleic Acid"

Radar and Electronics Association (at the Royal Society of Arts, John Adam Street, Adelphi, London, W C 2), at 7 p m —Mr Paul Thompson "Teaching by Electronics"

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W 1), at 7 30 p m —Mr D P Choyce "Personal Experience of Ocular Onchocerciasis in Central America, Africa and the British Isles" followed by a discussion

Thursday, December 12—Friday, December 13

Biochemical Society (in the Science Lecture Theatre, The University, Leicester), at 2 p m on Thursday—Colloquium on "Regulation of Microbial Metabolism", 10 10 a m on Friday—Original Communications

Saturday, December 14

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Dr P H Gulliver "Village Life in East Africa" *

Monday, December 16

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W C 2), at 5 30 p m —Mr W F Gibbons "Ceramic Sealing Techniques Applied to Electron Tubes and Semiconductor Devices"

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S W 1), at 5 30 p m —Mr A Stevenson "Analysis of Dithiocarbamates and Thiuram Disulphides Used in Agriculture A Collaborative Study of Macro-Methods Available for the Evaluation of Technical and Formulated Products"

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W C 2), at 6 30 p m —Sir Albert Mumford, K B E "Communications and Radio"

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 8 15 p m —Dr L S B Leakey "Exploring Man's Prehistory in East Africa"

Monday, December 16—Tuesday, December 17

British Biophysical Society (at the Institution of Electrical Engineers, Savoy Place, London, W C 2)—Symposium on "Control Mechanisms"

Monday, December 16—Wednesday, December 18

Institute of Physics and Physical Society, Electronics, Electron Microscopy and Analysis, and Low Temperature Groups (at Imperial College, London, S W 7)—Conference on "The Electrical and Magnetic Properties of Thin Films in Relation to Their Structure"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturer in the History of Science—The Registrar and Secretary University of Durham, Old Shire Hall, Durham (December 14)

Technician in the Department of Agronomy, University of New England for duties which will include the preparation of experimental material in glasshouses, the sampling of plant materials, and assistance with chemical laboratory work—The Registrar, University of New England Armidale, New South Wales, Australia, and The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, December 15)

Senior Lecturer, Lecturer, or Assistant Lecturer in Mathematics in the School of Mathematical and Physical Sciences—The Registrar, University of East Anglia, Earlham Hall, Norwich, Nor 05G (December 16)

Professor and a Senior Lecturer or Lecturer in Botany, and a Senior Lecturer or Lecturer in Zoology at the University of Khartoum —The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 20)

Senior Lecturer or Lecturer in Engineering Mathematics at the University of Khartoum—The Registrar University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 20)

Senior Lecturer or Lecturer in Electrical Engineering at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 20)

Assistant in Pathology in Queen's College, Dundee—The Secretary, University of St Andrews, Queen's College, Dundee (December 21)

Lecturer in Anatomy and Histology in the Department of Agriculture, Sutton Bonington, near Loughborough—The Registrar, The University, Nottingham (December 21)

Lecturer in the Department of Medical Physics—The Secretary, The University, Edinburgh (December 21)

Lecturer in Pure Mathematics—The Registrar, The University, Manchester 13 (December 28)

Research Officer (Biochemist) (with a Ph D degree or postgraduate research experience of equivalent standard and duration supported by satisfactory evidence of research ability, and preferably training and experience in mammalian biochemical research) at the McMaster Animal Health Laboratory, Commonwealth Scientific and Industrial Research Organization, Sydney, to undertake research in some aspects of chemical pathology, particularly in relation to the effects of parasitism—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2, quoting Appointment No 202/214 (December 28)

Chair of Chemistry—The Secretary, The University, Aberdeen (December 31)

Graduate in Mechanical Engineering or Applied Mathematics, to conduct research on an aspect of vibration concerned with transport—The Secretary, University College, Gower Street, London, W C 1 (December 31)

Lecturer (with an honours degree in pharmacy or the equivalent, and preferably subsequent specialization in physical chemistry) in Pharmaceutics at the University of Adelaide, Adelaide, South Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia, December 31)

Lecturers or Assistant Lecturers in Philosophy (including Philosophy of Science), Sociology, and Social Psychology—The Registrar, University of Sussex, Stanmer House, Stanmer, Brighton, Sussex (December 31)

Reader in the Electrical Engineering Department—The College Secretary, Welsh College of Advanced Technology, Cathays Park, Cardiff, quoting Ref No BH 233 (December 31)

Tennent Chair of Ophthalmology—The Secretary of University Court, The University, Glasgow (December 31)

University Tutor in Dental Anatomy—The Secretary, The Queen's University, Belfast, Northern Ireland (January 6)

Lecturer in Anthropology in the Department of Geography—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (January 15)

Lecturer/Senior Lecturer in Archæology (Greek and Roman Archæology) at the University of Sydney, Australia—The Secretary, The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, January 15)

Senior Lecturers or Lecturers in Anatomy (including Histology) and Physiology (including Biochemistry) at the University College of Rhodesia and Nyasaland Medical School—The Assistant Registrar, The Medical School, Birmingham 15 (January 15)

University Assistant Lecturer (preferably with a knowledge of South Asia, that is, Pakistan, India, Ceylon) in Social Anthropology—The Secretary of the Appointments Committee, Faculty of Archæology and Anthropology, The University, Downing Street, Cambridge (January 15)

Biochemist (Basic grade) at the City General Hospital, to work with, and assist, the Senior Biochemist—The Group Secretary, Stoke-on-Trent Hospital Management Committee, Princes Road, Stoke on-Trent

Electronic Specialist (with knowledge and experience of both valve and transistor methods) in the Department of Veterinary Physiology, to establish and take charge of an electronic workshop from January 1, 1964 The duties will include the construction, modification and maintenance of high-quality electronic apparatus used in biological research—The Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh

Graduate Physical or Inorganic Chemist (with some botanical knowledge, and preferably aged 25–30), for research on surface coatings and preservatives for wood—The Secretary, Timber Research and Development Association, St John's Road, Tylers Green, High Wycombe, Bucks

Master to teach Biology to "A" level, with some Chemistry and Biology, in the Middle School—The High Master, St Paul's School, London, W 14

Research Fellow or Research Assistant (with research experience, and for the Fellowship a Ph D in physics) in the Department of Physics, to work for one year on Admiralty sponsored research on the thermal properties of alkaline-earth oxides—The Registrar, The University, Keele, Staffs

Research Technician or Junior Graduate Chemist (with experience of, or an interest in, steroid chemistry) in the Department of Growth and Development, to assist in research on endocrinology of human growth —The Secretary, Institute of Child Health, Great Ormond Street, London W C 1

Senior Biochemist for the Department of Chemical Pathology in the Group Laboratory at Epsom District Hospital, for duties principally in laboratory supervision, with opportunities for conducting original work —The Group Secretary, Epsom District Hospital, Epsom, Surrey

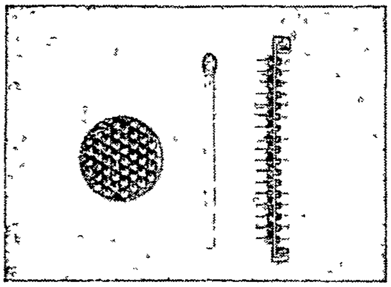
OXLEY

BARB INSULATORS

TYPE 062



Working voltage
500 V DC
Capacity less than 5 pF
Temperature range
−55°C to +200°C
Resistance to pull in either direction 3 lbs
Chassis thickness = 22/24 SWG = 022"/ 028" = 0 56/0 72 m/m
Mounting hole dia
062" = 1/16" = 1 58 m/m

A new subminiature insulator, which is speedy to assemble, and with outstanding physical characteristics The P T F E bush, which is supplied with the heavily silver plated brass 'barb' partly inserted, is located in an ordinary 062" dia hole and the barbed spill is pressed firmly through the assembly, thus expanding the P T F E bush on the far side of the chassis and locking the complete assembly firmly in the chassis

ULVERSTON, LANCASHIRE

[You decide:
is this a good idea?]

200 years ago life assurance as we know it began—with the Society that became known as the 'Old Equitable', the oldest mutual life office in the world

Unswervingly through the years, the 'Old Equitable' has stuck to its principles, of no shareholders, of paying no commission for the introduction of business and of sharing its profits among members Today, as helpful as ever and of great financial strength, the 'Old Equitable' provides life assurance for its members at cost price

For instance a quarterly payment of £26 7 6 secures a man of 34 an endowment assurance of £2,500, sharing in major profits and payable shortly before he is 60 or at his earlier death Those who took out such policies 25 years ago are receiving £4,315 this year

For more about 'Old Equitable' assurances, please fill in this coupon

APPOINTMENTS VACANT

UNIVERSITY COLLEGE OF RHODESIA AND NYASALAND

MEDICAL SCHOOL

SENIOR LECTURESHIPS OR LECTURESHIPS IN ANATOMY (INCLUDING HISTOLOGY) PHYSIOLOGY (INCLUDING BIOCHEMISTRY)

Applications are invited for the above Lectureships in connection with the new Medical School of the University College of Rhodesia and Nyasaland The School provides courses leading to the M B , Ch B degree of the University of Birmingham The first intake of students was in 1963 Salary scales Assistant Lecturer, £1,200 by £50 to £1,350 , Lecturer, Grade II £1 450 by £70 to £1,800 , Lecturer, Grade I, £1 880 by £80 to £2 200 , Senior Lecturer, £2,100 by £100 to £2,600 Passages to Salisbury for appointee, wife, and dependent children on appointment, with allowance for transport of effects Installation grant of £100 in addition for persons recruited from outside Africa Superannuation and medical aid schemes Unfurnished accommodation at rent of 15 per cent of salary Assistance given for triennial visits overseas

Detailed applications (six copies), naming three referees, should be sent not later than January 15, 1964, to the Assistant Registrar, The Medical School, Birmingham, 15, from whom further particulars may be obtained

---

UNIVERSITY OF EDINBURGH

DEPARTMENT OF MEDICAL PHYSICS

LECTURESHIP

Applications are invited for the post of Lecturer in the above Department Salary scale Lower, £1,250 by £110 to £1,690 , Higher, £1,805 by £115 to £2,150 by £110 to £2 700 per annum, with placement according to qualifications and experience, and with superannuation benefit and family allowance where applicable The successful applicant will include among his duties those of University Radiation Protection Officer and will be expected to undertake and supervise research in this and related fields

Further particulars may be obtained from the undersigned, with whom applications (six copies), giving the names of two referees, should be lodged not later than December 21, 1963

CHARLES H STEWART,
Secretary to the University

EPSOM GROUP MANAGEMENT COMMITTEE

Senior Biochemist required for the Department of Chemical Pathology in the Group Laboratory at Epsom District Hospital duties principally in laboratory supervision with opportunities for conducting original work Whitley Council salary and conditions £1 520 to £1,880 per annum

Applications stating age qualifications and experience, and giving names of two referees, to Group Secretary Epsom District Hospital, Epsom Surrey as soon as possible

---

UNIVERSITY OF EAST ANGLIA

SCHOOL OF MATHEMATICAL AND PHYSICAL SCIENCES

Applications are invited for posts of Senior Lecturer, Lecturer, or Assistant Lecturer, in Mathematics in the School of Mathematical and Physical Sciences from October 1, 1964 Preference may be given to applicants whose interests lie in continuum mechanics (in particular fluid dynamics), analysis, or statistics The salary scales are Senior Lecturer, £2 175 by £80 to £2 575 by £75 to £2,650 , Lecturer, £1 250 by £60 to £1 670 by £80 to £2 150 , Assistant Lecturer, £1 000 by £50 to £1 150, plus family allowance and F S S U benefits

Further particulars may be obtained from the Registrar University of East Anglia Earlham Hall, Norwich, Nor 05G to whom applications (four copies) (one copy only from overseas), should be sent not later than December 16, 1963

Ferranti electronics

have a vacancy for a

SENIOR PHYSICIST or CHEMIST

to lead a group working on SOLID-STATE LIGHT EMITTING DEVICES.

Candidates should possess a good honours degree and 2–3 years experience in solid state work, preferably with III–V compounds. Preferred age range 25–40 The appointment offers the opportunity of work with a high degree of scientific interest in a rapidly developing field

* **Application forms can be obtained from T. J. Lunt, Staff Manager, Ferranti Limited, Hollinwood, Lancs.**
Please quote reference JRP/15.

The Commission of the European Atomic Energy Community (EURATOM)

invites applications for the post of

SCIENTIFIC OFFICER

in the Biology Department of the Directorate-General for Research and Training, Brussels Candidates must be nationals of one of the Member States of the Community (Belgium, France, Germany, Italy, Luxembourg, the Netherlands), selection will be based on qualifications

Principal Qualifications Required

University degree, preferably in Physics Thorough knowledge of dosimetry of ionizing radiations with reference to biological systems

Maximum Age · 50 years

Languages:

Thorough knowledge of one of the following languages Dutch, French, German, Italian

Satisfactory knowledge of one other of these languages and, if possible, English

Closing Date for Receipt of Applications December 31, 1963

Further information, candidature requirements and **compulsory application form** are published in the Journal officiel des Communautés europeennes, No 165, November 16, 1963, which can be obtained on application to

H M Stationery Office,
P O Box 569,
LONDON, S E 1

Price One Shilling

CHLORIDE TECHNICAL SERVICES LIMITED

offer first-class opportunities for careers in

PHYSICAL CHEMISTRY

in their

RESEARCH AND DEVELOPMENT LABORATORIES

at Clifton, near Manchester, where research covering a wide range of scientific processes is being carried out in modern, well-equipped laboratories

The Company undertakes research and development for the Chloride group of companies who have world-wide interests in the manufacture of a range of products, including the well-known Exide, Dagenite and Keepalite batteries

Applications are invited for the following positions:

SENIOR PHYSICAL CHEMIST

The successful candidate will possess a research degree and have experience of a sufficiently high standard to enable him to direct a team of Physical Chemists studying the kinetics and mechanisms of reactions occurring in storage batteries and fuel cells

He will have the opportunity to attend International scientific meetings and the results of his work will be published in appropriate cases.

GRADUATE PHYSICAL CHEMISTS

Those appointed will undertake fundamental and applied research in electro-chemistry, including work on various battery systems and fuel cells They will possess an honours degree or equivalent qualification in Chemistry and have had experience in industrial or academic research

ASSISTANT PHYSICAL CHEMISTS

Candidates should have graduated recently or possess at least H N C in Chemistry Where applicable opportunities will be given for further studies at local Technical Colleges, both for day and evening courses

These appointments carry attractive salaries which are reviewed annually. There are good prospects of advancement for qualified Chemists with initiative, drive and enthusiasm

Excellent employee services are in operation, including a Contributory Pension Scheme

Applications, giving full details of age, qualifications and experience, should be addressed to

Chief Personnel Officer,
CHLORIDE TECHNICAL SERVICES LIMITED,
Exide Works, Clifton Junction, Swinton, Manchester.

UNIVERSITY OF OXFORD

DEPARTMENT OF ENGINEERING SCIENCE

There is a vacancy for a University Lecturer to take part in the research and teaching programmes of the Department The appointment will be at a salary in the range £1,250 to £2,285 (according to age), plus child allowances and F S.S U The post may be held in conjunction with a College Fellowship, and the attention of applicants is drawn to the advertisement for a Fellowship in Engineering Science at Lincoln College which also appears in this issue

Applications (five copies) should reach the Administrator, Engineering Laboratory, Parks Road, Oxford, from whom further particulars may be obtained, by December 31, 1963

APPLICATIONS ARE INVITED FROM recent graduates (male) in zoology or horticulture specializing in entomology for the post of Assistant Entomologist to work on the screening of new organic chemicals as potential insecticides Salary according to age, qualifications and experience —Applications, with full details, to Personnel Officer, The Murphy Chemical Co Ltd, Wheathampstead, St Albans, Herts

---

UNIVERSITY OF SHEFFIELD

DEPARTMENT OF APPLIED MATHEMATICS

Applications are invited for a post of Lecturer or Assistant Lecturer in Applied Mathematics to begin duties on October 1, 1964, or such earlier date as may be arranged Initial salary according to qualifications and experience on the scales Lecturer, £1,250 by £60 to £1,670 by £80 to £2,150, Assistant Lecturer, £1,000 by £50 to £1,150, with F S S U provision and family allowance A grant towards removal expenses will be made

Further particulars may be obtained from the Registrar, to whom applications (four copies) should be sent by December 31, 1963

UNIVERSITY OF HULL

DEPARTMENT OF CHEMISTRY

Technician Glass Blower (over 21) required for the Department of Chemistry Salary on scale £540 to £740 per annum, plus qualification allowance where appropriate Position on scale dependent on age and experience

Applications to Superintendent of Laboratories before December 13, 1963

THE AUSTRALIAN NATIONAL UNIVERSITY

HEAD TECHNICIAN FOR DEPARTMENT OF GENETICS

Applications are invited for the position of Head Technician in the Department of Genetics, The John Curtin School of Medical Research, Australian National University, Canberra, A C T The successful applicant will be responsible to the head of the Department and his duties will include supervision of technical staff, ordering of chemicals and apparatus, general administrative duties and laboratory service The Department is concerned only with research A wide experience of bacteriological and biochemical laboratory practice is required, and experience in the handling of laboratory animals would be an advantage The salary offered will be within the range £A1,884 to £A2,324 per annum The University will pay reasonable removal expenses and will provide assistance in obtaining housing for an appointment from outside Canberra The position carries superannuation, long service leave and normal fringe benefits

Applications should be forwarded to the undersigned at Box 4, G P O, Canberra, A C T, Australia by December 20, 1963

W S HAMILTON,
Bursar

PATHOLOGIST

Smith Kline and French is a leading company in the pharmaceutical industry and has an outstanding growth record

Continuing expansion has created an opening for an experienced histopathologist who will be required to establish and develop a pathology laboratory in our Research Department This appointment will offer considerable scope to a man or woman, aged under 40, medically qualified, with a wide experience of histopathology, particularly of laboratory animals

The salary paid will be in keeping with the importance of the post, and the other conditions, which include an excellent non-contributory Pension and Life Assurance Plan, are very good The Company pay generous allowances to new employees who have to move home on taking up their appointment

Please write briefly but concisely to

The Personnel Officer,
SMITH KLINE & FRENCH
LABORATORIES LTD,
Mundells, Welwyn Garden City, Herts
Quoting reference A 3638

HERTFORD COLLEGE

OXFORD

CENTRAL ELECTRICITY GENERATING BOARD

FELLOWSHIP IN ENGINEERING SCIENCE

The College invites applications for the above Fellowship, the Fellow to take up his duties as soon as possible and in any case not later than October 1, 1964 The appointment will be for three years in the first instance Duties to engage in full-time research, on a topic related to the scientific interests of the C E G B, in the University Engineering Laboratory, to assist in supervising research students in that Laboratory and to undertake a limited amount of teaching of undergraduates in the College Stipend in the range of £1,250 to £2,285, fixed according to age and the rules governing a comparable university post The Fellow will be entitled to free rooms and dining rights in the College He will be a member of the Governing Body of the College If married, the Fellow will be entitled, in lieu of free rooms to a marriage allowance of £150, and an allowance of £50 for each child

Applications and inquiries should reach the Principal, Hertford College, Oxford, not later than January 17, 1964

APPLICATIONS ARE INVITED FROM Physicists with Ph D for a position in the Department of Physics, at the University of Victoria, Victoria, British Columbia, Canada Duties, which will include teaching and research, will commence on September 1, 1964 Salary will depend upon qualifications and experience Salary floors at present are $12,000 for Professor, $9,000 for Associate Professor, and $7,000 for Assistant Professor —Applications and inquiries should be addressed to the Head of the Department of Physics

SCIENTISTS

for Information Work

UNILEVER has vacancies for

(A) A Chemist and a Physicist to work at Port Sunlight

(B) A graduate trained in the Chemical or Biological sciences to work at Colworth House

The successful candidates will contribute to the operation of an information service to laboratories employing about 120 graduate research scientists They will also investigate improved methods of handling information, e g punched card and computer techniques

Applicants, under 30, should have a good Honours degree or equivalent

Experience is preferred but is not essential

Apply (A) *to Staff Officer* (*Reference S 30A*),
UNILEVER RESEARCH LABORATORY,
PORT SUNLIGHT, CHESHIRE

(B) *to Staff Officer* (*Reference FRR/243A*),
UNILEVER RESEARCH LABORATORY,
COLWORTH HOUSE, SHARNBROOK, BEDFORD

UNILEVER RESEARCH

UNIVERSITY OF EAST ANGLIA

SCHOOL OF BIOLOGICAL SCIENCES

Applications are invited from plant physiologists or physical scientists interested in plant physiological problems for a post as a Senior Research Associate in the School of Biological Sciences The person appointed would be expected to work under the general direction of Professor J Dainty on a programme of ionic and water relations of plant cells and tissues financed by a grant from the Department of Scientific and Industrial Research The appointment would start as soon after January 1, 1964, as possible and would normally terminate on July 31, 1967 The salary scale is that for Assistant Lecturers in the University, namely, £1 000 by £50 to £1,150, plus family allowance and F S S U benefits

Further particulars may be obtained from the Registrar, University of East Anglia, Earlham Hall, Norwich, Nor 05G, to whom applications (two copies), should be sent not later than December 16, 1963

UNIVERSITY OF EDINBURGH

DEPARTMENT OF VETERINARY PHYSIOLOGY

Applications are invited for the post of Electronic Specialist to establish and take charge of an electronic workshop from January 1, 1964 Preference will be given to candidates holding Higher National Certificates The duties will include the construction, modification, and maintenance of high quality electronic apparatus used in biological research Knowledge and experience of both valve and transistor methods will be required Salary in the range £765 to £900 per annum, with placement according to qualifications and experience

Applications, stating age, qualifications and experience, should be sent to the Secretary to the University, University of Edinburgh, Old College, South Bridge Edinburgh as soon as possible

---

UNIVERSITY OF ALBERTA

Research Assistantships and Graduate Teaching Assistantships from $3,700 to $4,300 per year are available to students studying for degrees of Ph D and M Sc in Chemistry Travel allowance up to $250 is provided

For further information write Dr H E Gunning, Head, Department of Chemistry, University of Alberta, Edmonton, Alberta, Canada

---

PRINCE HENRY HOSPITAL

SYDNEY, AUSTRALIA

DIVISION OF CLINICAL CHEMISTRY

SENIOR SCIENTIFIC OFFICER (BIOCHEMIST)

Applications for appointment to this position are invited from graduates in science, or persons with equivalent qualifications, whose major subjects include biochemistry and/or chemistry and/or physiology A minimum of five years experience in clinical chemistry is required, and special training or experience in enzymology would be an advantage, though not essential Duties include assistirg with the maintenance and expansion of the clinical chemical services of the hospital (which is the main teaching hospital of the University of New South Wales Medical School), and with special investigations Current research interests include the clinical and laboratory aspects of protein separation, aromatic metabolites, metal-chelating agents, vaso-active peptides and enzymes of tissues and serum Additional information is available from the Head of the Division, Dr R J Bartholomew The range of salary, subject to variation with the male basic wage, is £A2,307 to £A2,382 to £A2,501, the initial salary being determined by qualifications and experience Conditions of service are in accordance with the Scientific Officers (Public Hospital Scientists) (Metropolitan) Award

Applications, in writing, showing age, marital state, and full details of qualifications and experience, together with names and addresses of two referees, should be addressed to the Chief Executive Officer, Prince Henry Hospital, Sydney, Australia Closing date January 31, 1964

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF CHEMISTRY

Applications are invited for two Lectureships in Physical Chemistry in the Department of Chemistry Preference may be given to applicants with a special interest in the study of synthetic high polymers or in the application of radioactive tracer techniques Initial salary in the scale £1 250 by £60 to £1,670 by £80 to £1,830 , £1,830 by £80 to £2,150, according to age, qualifications and experience, together with F S S U and family allowance benefits

Applications (three copies), naming three referees, should be sent by December 31, 1963, to the Assistant Registrar (Science), the University, Birmingham 15, from whom further particulars can be obtained

---

Broodbank Fellowships: Notice

Ordinances, pp 495 and 511 , *Supplementary Ordinances,* p 790

The Managers of the Broodbank Fund for the furtherance of research in Biochemistry or Biophysics with special reference to the Principles and Practice of Food Preservation give notice of their intention to proceed to the election of a Broodbank Fellow in the Easter Term 1964 The tenure of the Fellowship will be from a date to be determined by the Managers in consultation with the Fellow A Fellow will be required to devote himself to full-time research in a subject approved by the Managers

Candidature is open , but a Fellow must become a member of the University if he is not already a member of it, and of the Superannuation Scheme The tenure of a Fellowship, which will not normally exceed three years, will be determined by the Managers The research work will be carried out in Cambridge (or in part elsewhere with the Managers' consent) and will be subject to such conditions as the Managers may impose

The annual pensionable stipend of a Fellow is determined by the Managers, provided that it shall normally be not less than £750 nor more than £1,250, according to the Fellow's experience and qualifications In addition grants may be made by the Managers to cover expenses incurred by the Fellow in his work A Fellow must inform the Managers of the award to him of any other emolument or of his intention to undertake work other than work approved by the Managers, and he may in consequence suffer a reduction in his stipend He may, with the permission of the Maragers, undertake not more than six hours' teaching a week for remuneration without suffering any deduction from his stipend

Applications (ten copies) must be sent to the Registrary, at the University Registry, The Old Schools, Cambridge They must contain an outline of the candidate's proposed research, indicating how in his view this bears on the principles and practice of food preservation, and must be accompanied by a statement of his career and his date of birth, by copies of any papers he may have published or references thereto, and by the names of at least two referees Not more than two testimonials may also be sent No applications received after April 8, 1964, will be considered

---

MANCHESTER COLLEGE OF SCIENCE AND TECHNOLOGY

(FACULTY OF TECHNOLOGY IN THE UNIVERSITY OF MANCHESTER)

Applications are invited for new appointments as Lecturer or Assistant Lecturer in the Department of Mathematics, with corresponding title and status in the University of Manchester The sections of the Department especially interested in these appointments are those concerned with (a) pure mathematics, (b) statistics, and (c) engineering mathematics, and applicants should have already completed some research in one of these fields Commencing salary according to qualifications and experience in the scale Lecturer, £1,250 by £60 to £1,670 by £80 to £2,150 per annum , Assistant Lecturer, £1,000 by £50 to £1,150 Superannuation under F S S U Family allowances

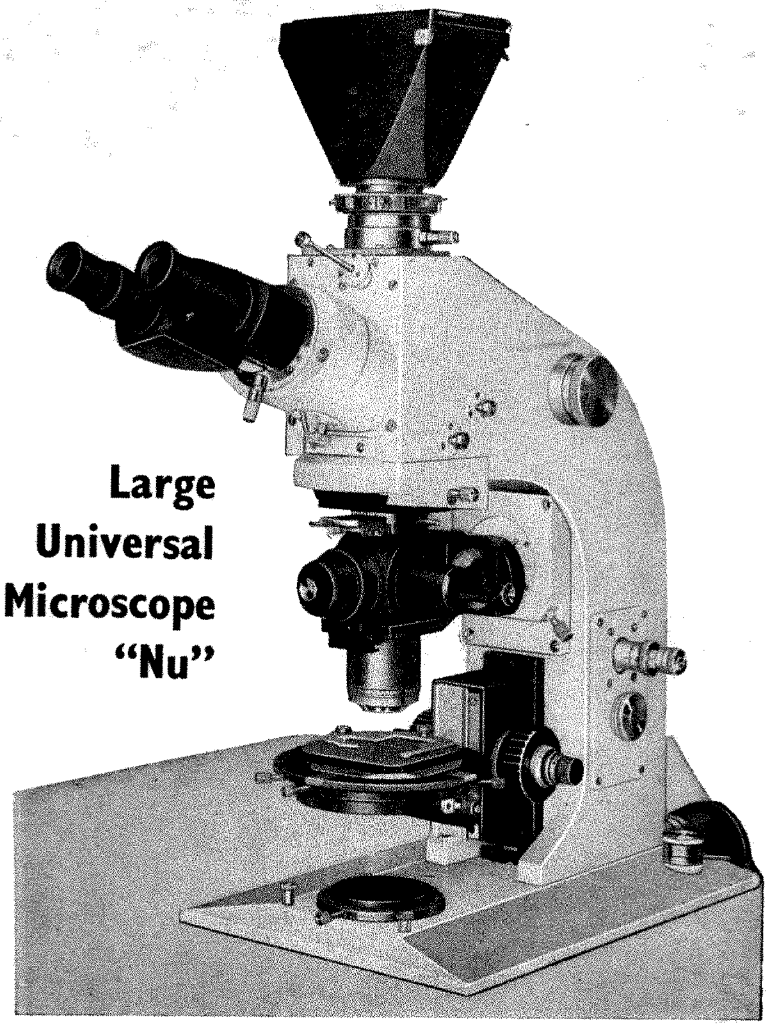
Conditions of appointment and forms of application may be obtained from the Registrar of the College, Sackville Street, Manchester, 1, to whom completed applications should be forwarded by Saturday, December 21, 1963

UNIVERSITY OF KHARTOUM

FACULTY OF PHARMACY

Applications are invited for a Reader or Senior Lecturer to act as Head of the Department of Pharmacognosy in the Faculty of Pharmacy at the University of Khartoum Salary scales Reader, £S 2 400 per annum , Senior Lecturer, £S 2,052 by £S 75 to £S 2,277 per annum Cost of living allowance approximately £S 180 per annum, at present Outfit allowance £S 50 Family allowances Wife, £S 60 per annum first child, £S 90 per annum , second and third child, £S 30 per annum each (£S 1=£1 0s 6d sterling) Passages for appointee and family on appointment, termination and annual leave There is a superannuation scheme and arrangements can be made to maintain F S S U policies Direct appointment on contract normally for five years with possibility of renewal (secondment welcomed if possible) Unfurnished accommodation provided at rent (excluding rates) up to 7½ per cent of salary

Applications (ten copies), detailing qualifications and experience and naming three referees, by December 20, 1963, to Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1, from whom further particulars may be obtained



Large Universal Research Microscope "Nu"

Permitting the employment of all classical and modern microscopic methods of examination in the visible spectral range. The Pancratic Eye-piece—an outstanding achievement of opto-scientific instrument making—serves as a stepless magnification variator.

Here, a problem shelved
is a problem solved—

Vacuum freeze drying, involving the sublimation of water from frozen material to leave a dry porous sponge which may be readily reconstituted, is today recognised as offering many advantages in the preservation of medical, veterinary, pharmaceutical, industrial and foodstuff materials. There are two techniques—"centrifugal" and "shelf" freeze drying, and Edwards have long specialised in supplying equipment for both.

The shelf method involves the loading of materials (prefrozen in some cases) on drying chamber shelves that can be refrigerated or heated to produce just the right conditions for rapid evaporation. "Speedivac" shelf dryers range from small laboratory apparatus to plant for very large scale drying, with drying chambers for up to 20,000 19 mm diameter vials. The chambers open on to a sterile area, and push buttons control an automatic operating cycle. Even larger plant is available to specification.

May we send you fuller details in Leaflet No. E.437/1?

'SPEEDIVAC' FREEZE DRYING EQUIPMENT

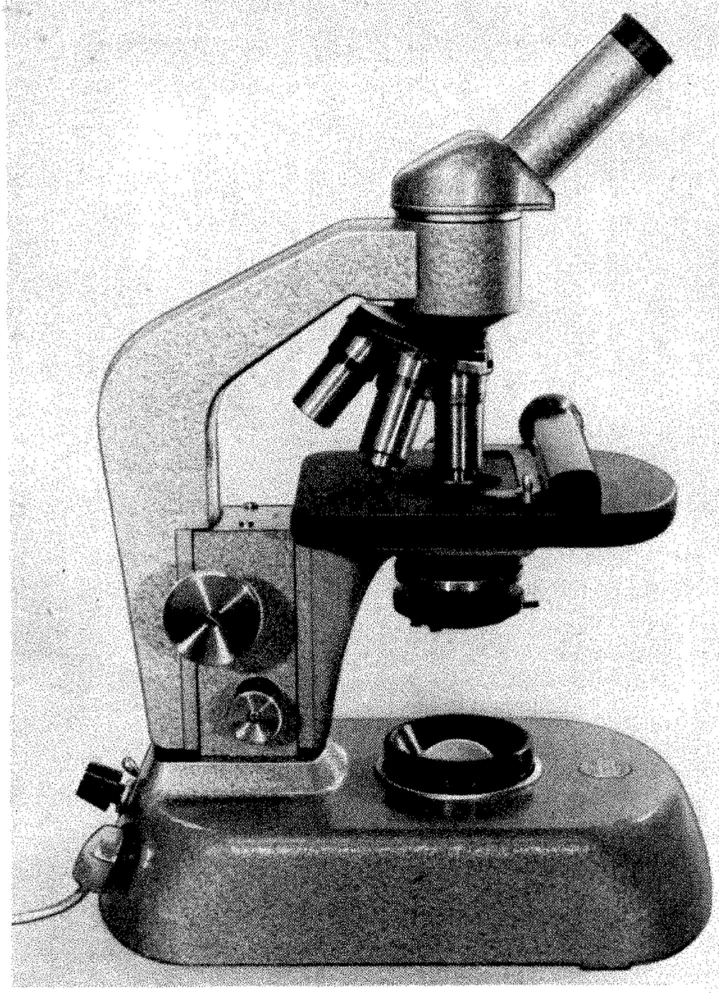
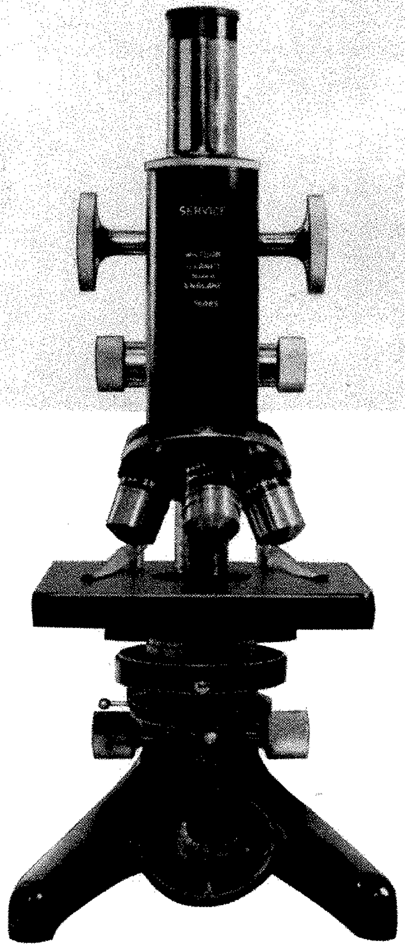
SERVICE

microscopes



New Service 3 microscope fitted with the Barnet Mechanical Stage and integral transmitted light base

TO THE SUCCESSFUL Service Range of microscopes Watson now add the Service 3, a robust, easy to use instrument that reflects the latest achievements in microscope design and technology. In the Service 3 long-term reliability and simplicity, essential to student use, are added to the versatility of optical and mechanical arrangements demanded by busy research laboratories. Highest standards of optical performance are assured by the new range of Watson objectives, sleeve-mounted, 4mm and 2mm spring-loaded for the protection of specimens, fully interchangeable and colour-coded for easy identification. The new objectives are available throughout the Service range, together with other recent developments including the Barnet mechanical stage *(illustrated above)*.



Service Microscope with quadruple nosepiece

OVERHAULING BRITAIN'S SCIENCE MACHINERY

IT is a remarkable tribute to the insight and thoroughness of the *Report of the Machinery of Government Committee*, prepared by a Committee under the chairmanship of Lord Haldane in 1918, that after nearly fifty years its views on the Government organization for scientific research should not only be quoted at length by Sir Burke Trend and his colleagues* but should also be regarded by them as providing a firm basis for meeting the needs of to-day, at least so far as the Research Councils and their relations to a Minister for Science are concerned This does not in any way detract from the value of the work which has now been carried out by the Trend Committee of Enquiry into the Organization of Civil Science, though it could not be suggested that its Report is a State paper comparable in significance with that of the Haldane Committee (see *Nature*, 103, 85, 1919) This is not because the Trend Committee has interpreted its terms of reference too narrowly or because it attempted to provide neat solutions without delving deeply into difficulties and underlying problems There is, indeed, one astonishing blind spot, the Report can be fairly criticized for not examining the problem of co-operative research in any depth Moreover, it does not consider more than rather superficially the problem of departmental organization of science, though the Committee in its remarks on the location of the Building Research Station and the Road Research Laboratory shows itself well aware of the essential conditions. Apart from this, the Report provides a fair and balanced review of the existing organization and the factors of which account must be taken However, it does not examine, as the Haldane Report did, the fundamental nature of the problem of tendering scientific advice in the process of Government and the principles to be observed

The Committee was appointed in March 1962 to consider (1) whether any changes were desirable in the existing functions of the various agencies, for which the Minister for Science is responsible, concerned with the formulation of civil scientific policy and the conduct of civil scientific research, and whether any new agencies should be created for these purposes, (2) what arrangements should be made for determining, with appropriate scientific advice, the relative importance in the national interests of the claims on the Exchequer for the promotion of civil research in the various fields, (3) whether any changes were needed in the existing procedure for financing these agencies or accounting for their expenditure It did not examine either issues of policy or consider the scale or content of research programmes, and the Report does not enter into the theory of organization The survey is based on the assumption that the Government's organization for promoting research and development in the civil field must be such as to ensure that the resources provided are used to the best advantage, that unnecessary duplication of effort is eliminated, and that new 'growing points' are fostered and encouraged

In its survey of the existing organization in Britain, the Report estimates Government expenditure on civil research and development in 1962–63 at £151 6 million, compared with £6 58 million in 1945–46 The major items are £50 million for the Atomic Energy Authority, £24 7 million for the Ministry of Aviation, £24 million in the universities (and learned societies), £21 4 million through the Department of Scientific and Industrial Research Besides expenditure of £6 million and £6 5 million, respectively, on the Medical Research Council and the Agricultural Research Council and £4 6 million on the Agriculture Departments, some £2 8 million is expended in other civil departments, £1 2 million on space research and £1 million each by the Admiralty on observatories and oceanography and by the Air Ministry on meteorology and aviation medicine Some £800,000 a year is expended by the Development Commission on scientific research

By and large, the factual survey led the Committee to conclude that in the aggregate the agencies concerned with promoting civil science do not constitute a coherent and articulated pattern of organization and that the arrangements for co-ordinating the Government's scientific effort and apportioning available resources on a rational basis are insufficiently clear and precise It does not suggest any criteria of coherence but considers that any satisfactory structure should permit and encourage common interests and shared purposes to transcend artificial limits of organization At present it sees some danger that the proper distinction between the roles of the universities and of the Research Councils may become obscured as a result of post-war developments which diminish the self-sufficiency of the universities as centres for promoting scientific research The Committee instances the inconsistency between the Admiralty's continuing responsibility for the Royal Observatory and the responsibility of the Department of Scientific and Industrial Research for other research in astronomy The division of function and responsibility for promoting development contracts between that Department and the National Research Development Corporation is also criticized, as well as the arrangements for co-ordinating the activities of that Department with the Ministry of Aviation and other departments

The present arrangements are not conducive to the concentration and flexibility which are becoming increasingly important in scientific research and development, nor does the Advisory Council for Scientific Policy, with its present inadequate staff and lack of responsibility for finance, possess effective means of influencing priorities. The composition of the Council is also criticized, the presence on it of official members who necessarily represent the several policies of the organizations which they serve is regarded as inconsistent with the conception of an advisory council The Trend Committee recognizes that the issues involved in deciding alike the nature, number and functions of the agencies required and of the organization to provide a comprehensive and coherent research strategy and advise on the distribution of resources, are complex, and it stresses the need for a revised form of organization to hold a fair balance between the freedom of thought and action desiderated by responsible scientific opinion and the national need for efficient use of resources Nevertheless, the attitude hitherto maintained by the

---

* *Committee of Enquiry into the Organization of Civil Science* Pp 59 (Cmnd 2171) (London H M S O, 1963) 4*s* net

Minister for Science can no longer prevail without modification, and some new arrangements must be concerted to correct the manifest deficiencies

So far as the universities are concerned, like the Robbins Committee†, the Trend Committee upholds the principle of the University Grants Committee and assumes that the universities' general income, from which their teaching and research functions are mainly financed, will continue to reach them in block grants, covering a period of years Nevertheless, it also considers that the system of additional earmarked grants, at present operated mainly through the Research Councils, is vital for the proper development of scientific research in the universities and should be continued It offers the indispensable safeguard to centralized provision as well as meeting the unforeseeable contingencies arising out of the rapid advance of science The Trend Committee does not believe that it would be a satisfactory arrangement for the University Grants Committee to assume the full responsibility for university research, including the functions at present exercised by the Research Councils

On the contrary, the Committee considers that, subject to certain safeguards, the present system provides the most satisfactory arrangements for the support of science in the universities, and it suggests that the partnership between the universities and the Research Councils should be extended to deal with the problems that arise from the increasing costliness of certain types of essential equipment Safeguards are needed, however, to ensure that the earmarked grants do not become so large in scope and scale as to distort the pattern of university research The Trend Committee was not satisfied that Research Council grants for specific projects always covered the real costs of these projects, including the overheads and provision of technical assistance and accommodation. It thought that this question required further consideration by Research Councils and welcomed the recent decision to allow Research Councils to supplement grants for postgraduate training by contributions towards the incidental costs of equipment, etc Further, it insists that, in apportioning their general income, the universities must bear in mind the needs of the country in research no less than in teaching, and that an effective means must be provided for ensuring that financial responsibility for research projects is transferred from the Councils to the general income of the universities when the research which the Councils have been supporting becomes an integral part of the work of the universities and when new subjects, developed from these researches, ought to be incorporated into the general university structure

Such a procedure has already been devised and used for the transfer to university general funds for the 1962–67 quinquennium of 16 per cent of expenditure previously financed by the Research Councils, and the Trend Committee is satisfied that this procedure provides the necessary safeguard It is also satisfied that the universities generally accept their responsibility for national needs in research, and although the Committee is well aware that the research needs are liable to be overlooked when universities are being asked to concentrate their resources on increasing the number of places available for students, the Robbins Report lays sufficient emphasis on the expansion of postgraduate activities and on the development of research to suggest that the danger is not very serious Further, the Trend Committee urges the Research Councils to consider the establishment of units within, or in association with, universities as an alternative to the creation or expansion of separate research institutes It also suggests a modest expansion of the system of Research Professorships of the Royal Society and that the universities might direct attention to the provision of a larger number of professorships and other senior posts in their science departments—the Committee insists that, in the long-term, university finance should be on a scale sufficient to permit the creation of such posts out of general income

The Report recommends no change in the present functions of the Medical Research Council or the Agricultural Research Council, though the Committee suggests that when the latter Council has completed a current review of facilities for research in relation to processing imported food, existing arrangements for research on food-processing should be examined in more detail On the other hand, the Committee finds the present combination of responsibility for scientific research with that for industrial research and development in the Department of Scientific and Industrial Research unsatisfactory It unhesitatingly recommends the dissolution of that Department and the distribution of its functions and responsibilities between three new agencies, all responsible, like the other two Research Councils, to the Minister for Science Two of these will be Research Councils—a Science Research Council and a National Resources Council—and the other, in view of the executive character of some of its functions, which will include those now exercised by the National Research Development Corporation, will be an autonomous agency, the Industrial Research and Development Authority

If the Committee's recommendations were followed up, the Science Research Council would assume the responsibility for the support of relevant research in universities and similar institutions as well as for postgraduate awards in science and technology, and its activities would not be so narrowly interpreted as to hinder it from fostering the expansion of technological research, whether in universities or other institutions, on which the Robbins Committee lays emphasis It is not to be confused with the Advisory Council on Scientific Policy, which is to be reconstituted with the authority and resources that its status as the chief advisory body to the Minister for Science demands Initially, the Science Research Council is conceived as being organized in six divisions, based on scientific disciplines, and including responsibility for financing the National Institute for Research in Nuclear Science, for the scientific aspects of the United Kingdom's relations with the Council for the Encouragement of Nuclear Research, for the supervision of the scientific space research programme and for the United Kingdom's interest in the European Space Research Organization It would assume direct control over the Royal Observatories, but responsibility for the Meteorological Office should remain with the Air Ministry The Report makes no attempt to define the precise nature of the organization required, but it points out that the new Council must also be prepared from the start to encourage activities devoted to the synthesis of scientific experience, including new applications of scientific method, and that additional divisions for the purpose should be established as required Any means of providing the scientific basis for working out policy such as Dr S Toulmin has suggested could presumably be fitted in at this point (see *Nature*, 200, 503, 1963).

---

† Committee on Higher Education *Higher Education Report of the Committee appointed by the Prime Minister under the Chairmanship of Lord Robbins* Pp xxi + 335 (Cmnd 2154) (London H M S O, 1963) 15*s* net See also *Nature*, **200**, 925 (1963)

The recommendation for the establishment of a National Resources Research Council follows the recommendations of the Report of the Committee set up in 1961 under the chairmanship of Sir William Slater by the Advisory Council on Scientific Policy This Council should be responsible for all the functions now exercised by the Nature Conservancy, including the management of nature reserves, the Trend Committee agreeing on this last point with the Advisory Council rather than with the majority of the Slater Committee It would also be responsible for research into hydrology, fisheries and related aspects of aquatic biology, though not for the management of the Departmental fisheries laboratories and the Torry Research Station, for the Geological Survey and the Soil Surveys, for long-term forestry research, and for research into oceanography, although administrative responsibility for the National Institute of Oceanography would remain with the Admiralty The Development Commission's research activities in fisheries, oceanography and marine biology should also be transferred to agencies under the new Council, but further consideration of the future of the Commission is called for, particularly with reference to its responsibilities in rural development and rural sociology

In some details, as indeed is already indicated, these proposals do not follow the recommendations of the Slater Committee, as the Trend Committee had reservations about some of the detailed recommendations, but it agreed that existing arrangements for promoting scientific research in ecology are deficient and that it would be right to bring together, in one organization, work which is now the responsibility of various agencies The Trend Committee does not propose to transfer to the new Council at present either the Water Pollution Research Station or the Hydraulics Research Station, but the Hydrological Research Unit should be transferred, and the new Council should also be responsible for the existing Committee on Hydrological Research The majority of the existing research stations of the Department of Scientific and Industrial Research would be transferred to the new Industrial Research and Development Authority, and one of the six divisions of this Authority envisaged would be devoted to their administration

Another division of the Authority would be responsible for grants for applied research or specific research projects in the industrial field, and it is suggested that the Human Sciences Committee of the existing Department might form part of this division The support of industrial research associations would fall to a third division, and it is suggested that a first task of the new Authority would be to consider whether any changes in the organization of the associations, the scale of their operations or the method of financing are required The Trend Committee seems to accept the view that some of the smaller associations could be amalgamated with advantage, and it proposes the same division should be made responsible for the unit created for promoting operational research in industrial operations Another division would continue the work at present sponsored by the Department's Economics Committee of technico-economic surveys of certain industries in relation to their needs for research and development, and this division in particular would have close relations with the National Economic Development Council

A main reason for advocating the establishment of the new Authority is the Trend Committee's belief that considerable development of the Department of Scientific and Industrial Research's activities in industry is required, particularly in relation to the activities of the National Economic Development Council and, in promoting development contracts, the National Research Development Corporation Such development the Committee regards as of major and growing importance, and its proposal that the work of the Corporation and the Department's activities in this field should both be transferred to a Development Division of the Authority, operating on similar lines to the Corporation and with a like measure of independence but relieved of the statutory obligation that its operations should break even, is obviously sound Further, the Trend Committee suggests that this Development Division should be authorized to stimulate Departments to place development contracts for new inventions and equipment, playing a positive part and encouraging initiative

The Committee's recommendations for the dissolution of the Department of Scientific and Industrial Research and for the re-grouping of its functions are logical and seem fundamentally sound They should eliminate some of the present weaknesses and should also increase the effectiveness of the National Research Development Corporation Moreover, the Committee is well aware of the importance of effective co-operation between the various Research Councils themselves and between the Councils and Government departments and other organizations, including the defence departments Although no specific arrangements are suggested, the desirability of a close link between the Ministry of Defence and the Industrial Research and Development Authority is particularly desiderated Further, the new Advisory Council to the Minister for Science, which, it is recommended, should replace the present Advisory Council on Scientific Policy, with similar terms of reference but consisting entirely of independent members, half of whom should be scientists, some industrialists and some with wide experience of public affairs, provided with adequate staff and resources, should supply the necessary oversight and co-ordination

That Council, however, is part of the new arrangements proposed in regard to the Minister for Science, but there are two further matters which should be noted first One of the six divisions initially suggested for the Industrial Research and Development Authority is concerned with the dissemination of scientific and technical information, including the co-ordination of information activities throughout the Authority It is recommended, however, that the Office of the Minister for Science should take over the management of the National Lending Library for Science and Technology and the support of the Association of Special Libraries and Information Bureaux This again is an improvement on the present arrangements, but it is still only a first step For all its recognition of the value of information work, the Trend Committee shows no appreciation of the importance of a national library policy Arrangements which leave the management of the National Lending Library for Science and Technology and of the new National Reference Library for Science and Invention in different hands are not ideal, and the proposals here are only acceptable as an expedient while the wider issues of ministerial responsibility are being decided

The second matter is one on which the Trend Committee displays an extraordinary lack of insight It blandly proposes that the Overseas Research Council, which in 1959 replaced the Colonial Research Council, should be dissolved, suggesting that it has now discharged its functions The Overseas Research Council has, in fact, never issued a report and it would be more accurate to suggest that it has never functioned Since the Colonial Research Council was dissolved, the Government has drawn a veil over overseas research in spite of its increasing importance and urgency, and the importunities of those who recognize what is at stake have had no effect on either Government or Opposition The two great political parties have both been content to watch the leadership, which Britain once gave and should still be giving in this field, pass to the United States, the Department of Technical Co-operation has so far been unable to break the silence or end the neglect. While the Trend Committee does, in fact, admit that research in less-developed countries should not be neglected entirely and that the Department of Technical Co-operation is a less suitable means for furthering such efforts than a research council, its proposal that this should be included among the responsibilities of the Minister for Science for the Government's international relations in scientific matters is entirely inadequate The Committee's lack of vision and appreciation of Britain's place in the world of to-morrow is a blot on an otherwise sound and constructive Report

Of the further changes recommended in regard to the Minister for Science, it will suffice to note here that it is proposed he should assume additional substantive responsibilities for promoting civil scientific research and development, particularly as regards the allocation of available funds, and that the power to appoint the governing bodies of the several research agencies and the authority to issue formal directions should be vested in him and not, as at present, in Privy Council Committees The Report shatters the attempt which the Minister has so long maintained to operate with a minimal Office and recommends strengthening his staff and facilitating exchange of personnel between his Office, the headquarters of the research agencies and the stations which they operate Here, generally, it is in line with the recommendations for a Science and Policy Office considered at the Ministerial Meeting on Science in Paris in October (*Nature*, 200, 719, 1963)

Leaving for later discussion the question of arrangements at ministerial level in the light of any decision regarding responsibility for higher education, etc , the Trend Committee's proposals offer opportunities for immediate action to improve the present arrangements However, while that action is being taken, the matters which the Committee has left on one side, such as co-operative industrial research and the future of the research associations and the location of some of the research stations, could be further studied There is no *a priori* reason why the new Advisory Council, the Councils for Science Research and National Resources Research and the Authority for Industrial Research and Development should not be established as quickly as possible, though this will require legislation, and the process may well provide a touchstone of the sincerity of the support which the political parties promise to scientific and technological work There are points on which considerable difference of opinion is possible, but the differences do not lie on party political lines, and the proposals of the Trend Report offer a means of rectifying some of the present weaknesses in the organization of civil research in Britain which calls for firm support from all political parties

RESEARCH MANAGEMENT

Scientists in Industry

Conflict and Accommodation By Dr William Kornhauser, with the assistance of Warren O Hagstrom Pp xii+230 (Berkeley and Los Angeles University of California Press, London· Cambridge University Press, 1962) 6 dollars, 48*s*

Managing Creative Scientists and Engineers

By Eugene Raudsepp Pp xvi+254 (London and New York Collier–Macmillan, Ltd , 1963.) 55*s*

BOTH books are concerned essentially with the theory and practice of research management, but in approach, as well as in style and treatment, they are in sharp contrast Dr. Kornhauser examines the conduct and management of research as an example of the relations between professional workers and the industrial and other organizations by which they are employed, and if he is inclined at times to exaggerate the conflict and strain which may arise between professional interests and those of Government or industry, his book is an important contribution to the discussion of the place and functions of the professions in the technological society of to-day He takes up the examination where Carr-Saunders and Wilson left it thirty years ago, but with due acknowledgment to the subsequent investigations of Lewis and Maude Dr. Kornhauser does not accept without reservation Carr-Saunders and Wilson's view of the professions nor does he give any precise definition to put in its place Nevertheless, he recognizes the importance and value of that earlier work, if he seems rather to overlook the stress which they laid on a profession as providing the permanent anchorage and shelter which are the prerequisite for independence and integrity in professional service to society

Dr Kornhauser's book is based on the findings of an investigation he conducted as a member of the Institute of Industrial Relations of the University of California among a group of scientists and engineers engaged in industrial research, mostly employed by industry, but some by Government and independent research organizations At the outset he outlines the ways in which tension is liable to arise between professional ideals and interests and the objectives of the organization in which the scientist or engineer is employed This is followed by discussions of professional goals in industry, the ways in which professional controls can be exercised in industry—and here he discusses the management of research more specifically—professional organizations and their relations with industry, professional incentives in industry, professional influence in industry, and, finally, the adaptations of the professions and industrial organizations towards one another Dr Kornhauser is writing in an American context and it is important to remember this in reading his forthright rejection of the Trade Union, but he is not unmindful of conditions in Britain, though he makes no reference to the work of such bodies as the British Association of Chemists, the Association of Scientific Workers or the Institution of Professional Civil Servants

Such omissions apart, Dr Kornhauser deals fairly enough with the main problems that arise in the relations of professional men with industry or indeed with society in general, and with the functions of the professions to-day now that such a high proportion of their members are now no longer self-employed but employees The implications for the future are indicated clearly enough, and while, as already noted, Dr Kornhauser's first preoccupation is with the American scene, his vision is much wider, and an excellent bibliography is not limited to American sources but includes the major contributions from Britain Well written and substantially free from jargon, it will be read with interest by scientists and professional men generally and not simply by those concerned with the practice or management of research

While the research manager will find many points for reflexion if not suggestions for practice in Dr Kornhauser's book, that of Dr Raudsepp, directed specifically at the research manager, appears to be addressed also to the managed, at least to judge by an appendix, "Increasing your creative problem solving ability", which seems somewhat out of place, though in themselves, if adopted, some of the suggestions might assist the scientist in adjusting himself to industry Dr Raudsepp, in fact, does not seem quite sure of himself or of the type of reader he is addressing He begins with two chapters dealing with the creative process and the characteristics of the creative professional, but it is never clear whether he is concerned essentially with discovery or with invention. Failure to make the distinction confuses much of his writing throughout the book, and this part also illustrates another main weakness While an understanding of the nature of discovery and invention and the conditions most favourable to them is a logical starting point in considering the management of research workers, the examination of the creative process is far too superficial and is limited to American sources Apart from Ghiselin, scarcely a major contribution is mentioned, and for an understanding of the creative process itself one must still turn, for instance, to the writings of J L Lowes and J J Thomson and Sir Henry Dale, to Mrs Jacquetta Hawkes's talk on her father, Sir F Gowland Hopkins or to C Nicolle's little book, *Biologie de l'Invention*

For the research manager, however, the essential thing is to understand the conditions for creative work in which the mind has free play, and the second part of the book discusses the factors in the general climate of culture and industry in the United States which inhibit or stifle creative work or that favour its expression In the second of these chapters, Dr Raudsepp makes several suggestions for changing the industrial conditions so as to promote creative work and initiative, but it is in the third part of the book that he addresses himself specifically to the problem of managing creative research, and by that he means essentially fundamental research Here again there is some confused thinking, and particularly when he comes to discuss the work of teams or groups, where a number of assumptions are open to question Nor does he attempt to distinguish between supervision and management of research, though what reads like a deliberate attempt to obliterate a distinction recently emphasized by a Working Party of the Federation of British Industries seems, on the contrary, to demonstrate the validity of the distinction

His concluding chapter is entitled "Supervising Creative Professionals" and is concerned with what in Britain would be generally understood as the management of fundamental research Much in this chapter, and also in the suggestions made regarding incentives in the preceding chapter on motives of creative workers, is essentially sound, though sometimes it verges on the trivial and at other points is controversial, if not provocative

By and large, Dr Raudsepp is inclined to be too sweeeping in his generalizations, particularly about people, and his heavy, sometimes staccato, style does not make for easy reading Here and in his excessive use of jargon, not always self-explanatory, the absence of any bibliography, and the fragmentary character of his references, his book contrasts sharply with Dr Kornhauser's Industrial research managers who read this book will doubtless find some useful suggestions, though some may have considerable reservations, and its practical value is likely to be in direct rather than in inverse proportion to their own experience and vision

R BRIGHTMAN

MONOPHYLETY VERSUS POLYPHYLETY

The Origin of Races

By Carleton S. Coon Pp xli + 724 + xxi + 32 plates. (London Jonathan Cape, 1963) 63*s*. net.

THE classical view of the origin of the present-day races of man is one of comparatively recent diversification from a single stock However, as ever more fossil remains are discovered, it becomes increasingly likely that the species *Homo sapiens* did not arise in a restricted area, and that there never was a single stock in the sense of a particular geographical group of populations There is still considerable controversy as to what fossil hominids should be included within the taxon *Homo sapiens* Many of the arguments result from the difficulty of recognizing palæospecies It is evident that if the fossil record were complete the making of taxonomic groups within the evolutionary continuum must involve putting father and son in different categories at some level or other When there are data on the ecology and size of fossil populations it is occasionally possible to bring some objectivity to a taxonomy of evolutionary clades, but in most cases, and certainly so in palæoanthropology, classifications must perforce be essentially arbitrary In the past, much use was made of the 'gaps' in the fossil record, but many of these 'gaps' have now been filled and the ancestry of present-day man can be traced back to at least the Middle Pleistocene with a reasonable degree of certainty There is an increasing tendency to refer all these ancestral forms to the species *sapiens* not only because of the cladal continuity but also because of the many otherwise unique features which are shared with present-day man

If then the species, in this sense, is quite old the possibility exists that the races of man are also old, but there is variable opinion as to how old Coon, in this book, maintains that the major races are extremely old and that they were differentiated at least as early as the base of the Middle Pleistocene Unfortunately, he does not systematically present and evaluate the evidence for this view, and in the main it is left to the reader to extract the relevant information from the wealth of data which is given in a descriptive way about not only all fossil hominids but also the rest of the Primates It would seem, however, that particular importance is attached to two facts In the first place, Coon points to the immense differences which exist between the languages of the world to-day, and considers that such diversity must indicate long separation This theme, however, is not developed, and his remark that "it takes 20,000 years for two sister languages to lose all semblance of relationship" would seem to indicate that the evidence is not of any great relevance anyway It is doubtful if anyone thinks that the differentiation of the major present-day races did not begin considerably earlier than this The second type of evidence is more compelling and rests on the occurrence of distinctive racial characteristics in both the present-day populations of large geographical areas and in fossil populations from the same areas Coon considers that there is a more or less complete morphological sequence of forms connecting the present-day Australoids with Java man, and he recognizes distinctive mongoloid features in the fossil hominid remains from Eastern Asia, including Peking man, Caucasoid features in the European fossils, and Capoid (Bushman-Hottentots) and Congoid (Negroid) features in some of the ancient remains from different parts of Africa These distinctive geographical patterns are interpreted as indicating separate phyletic descent for at least these five major races of man from the times of Java and Peking man Since the latter are usually included in a different species (*H erectus*) from modern man and some would consider that the differences are so large as to warrant generic status (*Pithecanthropus*), such a view implies extremely extensive parallel evolution.

To account for this parallelism, Coon points out that most of the changes which occurred during the later phases of hominid evolution are, in the evolutionary sense, general improvements, and that, therefore, selection would have favoured them in all environments and every geographical population. In such polyphyletic gradal evolution, however, it is unlikely that the rates of change will be similar in each area, and one would, therefore, expect that some populations are in the biological sense more primitive than others. As evidence of biological primitiveness, Coon points out that the Tasmanians at the time of their discovery were "living in a culture 100,000 years old". He considers, in fact, that some races have only just crossed the *sapiens* species boundary, while others did so some considerable time ago.

It is perhaps this conclusion more than any other which has been responsible for the bitter acrimony with which this book has been received, since it implies that some races of present-day man are biologically inferior to others. However, quite apart from these unfortunate overtones, for which there is no objective scientific evidence, there are a number of objections to Coon's view. The main one, of course, is that all present-day populations of man will naturally interbreed and produce fertile offspring: that they are, in fact, only races of the same species. Had they evolved completely separately from one another, it seems extremely unlikely that the many differences between *erectus* and *sapiens*, even if phenotypically established five times over, would be genetically established in more or less the same way on each occasion.

It seems far more probable that the similarities between present and past populations of the same geographical area, which Coon uses as primary evidence for his polyphyletic theory, represent convergence. It is to be expected that populations living under comparable ecological conditions will evolve similar adaptations. There is, in fact, fairly good objective evidence that such convergence has occurred. Almost certainly it accounts for many of the similarities between African negroids and Melanesians, and between the Eskimos and the people who occupied Europe during the Wurm III glacial period.

This is not to say that Coon's view is completely untenable. In the first place, it is rarely possible in palæoanthropology to prove a hypothesis wrong: the best that can usually be done is to balance the various possibilities in the light of general evolutionary theory. On this score, Coon's hypothesis seems extremely unlikely in that it calls for an unprecedented degree of parallel genetic change. On the other hand, there can be little doubt that hominid evolution is largely a gradal phenomenon and that selective pressures must have been qualitatively similar the world over. The real point at issue is the extent to which past populations were reproductively isolated from one another. Coon acknowledges that gene flow must have occurred at times, but discounts its effects. Yet it seems likely that such gene flow was, in fact, the very agent by which all populations obtained the same genetic basis for their gradal evolution, and it would, of course, act to keep the species intact. Perhaps one of the most important factors determining human evolution has been the widespread movement of populations within, geologically speaking, short periods of time.

The most reasonable view of the terminal phases of human evolution is of the species evolving as a whole the world over. It could well be that there is temporal continuity between the particular ecological adaptations of present populations and those found in ancestral groups, but the important point is that *Homo sapiens* has a monophyletic rather than a polyphyletic origin.

While most anthropologists will find the general thesis of this book unacceptable, everyone must be indebted to Coon for the detailed account he provides of the fossil hominids. Practically all the authenticated remains are fully described, including many remains which, even for palæoanthropologists, have been little more than names. There are errors of fact, perhaps more than one expects in even such an extensive review, and English readers may well find the writing stylistically irritating, but this is a comprehensive up-to-date document of human evolution and an invaluable reference book.

G. AINSWORTH HARRISON

EVOLUTION IN FORAMINIFERA

Evolutionary Trends in Foraminifera

Edited by G. H. R. Von Koenigswald, J. D. Emeis, W. L. Buning, and C. W. Wagner. (A collection of papers dedicated to I. M. Van der Vlerk on the occasion of his 70th Birthday.) Pp. viii + 355. (Amsterdam and London: Elsevier Publishing Company, 1963.) 45 D.fl.; 90*s*.; 50 D.M.

FORAMINIFERA are small in size and occur in most marine sediments. They have been abundant since the Upper Palæozoic and have shown well-marked evolutionary changes since their appearance in the Cambrian, providing unique opportunities for investigations of populations through space and time. An enormous amount of work has been published on this group, stimulated by their stratigraphic importance and consequent economic value in oilfield exploration and development. It might, therefore, be expected that the main lines of evolution would be known and important principles deduced relating to the theory of evolution in general. The publication of this well-produced, well-illustrated book which brings together fourteen papers by different authors enables us to take stock of progress in this field.

Modern classification of Foraminifera leans heavily on the evidence of wall structure, recapitulation and the stratigraphic succession. These papers show that great progress has been made both in the investigation of the basic structure of the shell wall, regarded as a progressive evolutionary character, and also in detailed knowledge of the stratigraphic succession. In general the principle of recapitulation is accepted but not, apparently, by all the authors. Family relationships are now seen to be more complicated than was thought, even a few years ago, with parallel development along many lines. The sheer amount of new knowledge that has accumulated is well shown by Cita-Sironi. This author points out that the few species known in the Globotruncanae before 1940 have now swollen to more than one hundred, while, instead of one genus, *Globotruncana*, there are now twenty-three.

Dunbar outlines very clearly the main trends in the Fusilininae and Schwagerininae. These include development of inner and outer tectoria in the Fusilininae and increase in size and honeycombing of the layered, granular wall in the Schwagerininae. Both sub-families developed folded septa. Dimorphism became emphasized in the Permian with appearance of gigantic, microspheric individuals. These trends are well expressed stratigraphically and the idea of recapitulation is supported by the presence of a flat, initial spire in microspheric forms which is taken to indicate descent from *Endothyra*. Rauser-Chernousova also supposes that evolution in this group is characterized by recapitulation, with descent from the endothyrids, but her evolutionary scheme differs in detail. The value of species and genera in intercontinental correlation is discussed and a distinction drawn between conservative, ancient families and advanced families with genera of short range.

The trend towards accentuated dimorphism also occurs in the Nummulitidae, discussed by Schaub. Again, the shell tended to become larger and adult chambers longer and lower through Palæogene time. Morphological continua are also traced in great detail in the Miogypsinidae (Drooger) and Orbitoidae (MacGillavry) with analysis of equatorial chamber pattern and nepionic reduction. The presence of a gumbeline initial part is confirmed in the Orbitoidae which throws an unexpected light on their possible ancestry. Phyletic relationships in the Miliolidea are also discussed (Smout).

Doubt is thrown on the principle of recapitulation so far as the Lagenidae are concerned, by Brotzen, who derives *Lenticulina*, *Frondicularia* and *Nodosaria* independently from layered, granular palæonodosarids allied to *Nodosinella*, through granular and fibrous mesonodosarid intermediaries in the Triassic and Liassic. The Rotaliidea and Buliminidea are considered to be derived through the Triassic Duostominidae from either the Endothyridea or the Trochamminidae. The possibly independent origin of *Globigerina* from arenaceous ancestors is also suggested. This stimulating paper will undoubtedly cause controversy. Evolution in the Lagenidae is also considered by Barnard, who shows that an explosive burst of evolution occurred in the Lower Jurassic with variation in general morphology. Variation in ornament occurs later and in *Lingulina* and *Frondicularia* progressive evolution of ornament is of stratigraphical value. Rather similar variation in ornamented species of *Bolivina* is of value in Upper Cretaceous stratigraphy (Hiltermann).

This new work supports the idea that the Lituolidea, Endothyridea and Miliolidea are well-defined groups (Glaessner). Relationships in the Rotaliidea s l and Buliminidea are, however, complex and investigations have not gone far enough for the main evolutionary lines to be made clear.

Although Rat relates the architecture of the Orbitoline test to sedimentary milieu and Hottinger relates the shape of the Alveoline test to changes in surface/volume ratio of the endoplasm, little is known of the adaptive significance of most morphological trends. This is largely due to lack of work on living Foraminifera, consequent in part on the difficulty of making observations with the ordinary microscope. The extended use of electron microscopy may be expected to throw a flood of light on the structure and adaptation of modern forms.

Biologists as well as palæontologists should read this book. We may then expect an equally impressive symposium on Dr Van der Vlerk's eightieth birthday.

J HAYNES

HABITATS OF THE PAST

Principles of Paleoecology

An Introduction to the Study of How and Where Animals and Plants Lived in the Past. By Derek V Ager. Pp xi+371. International Series in the Earth Sciences (New York McGraw-Hill Book Company, Inc , London McGraw-Hill Publishing Company, Ltd , 1963) 83*s* 6*d*

IN the past twenty-five years or so a vast number of papers on various aspects of palæoecology have been published. In view of this interest it is surprising that a text-book on the subject written in the English language has not hitherto appeared. Dr Ager is to be congratulated on providing such a book.

Principles of Paleoecology is a compact volume divided into three parts. The first introduces the subject briefly and explains the principles involved and the relationships to kindred subjects, the second describes in some detail methods of determining the ecology of fossil taxa, the third discusses the ecology of fossil communities. After the niceties of the introduction are dispensed with the meat of the book begins. In the second part (termed 'paleoautoecology') the author reviews various methods of interpretation such as comparative anatomy and physiology, comparative habit and habitat, the problems involved in the interpretation of extinct groups, shell orientation and its significance, organic associates and trace fossils. Discussion of fossils and the sedimentary environment is treated both in this and in the subsequent part, but the author feels that a discussion of the sediments themselves has no place in the book.

In the third section, 'paleosynecology', topics include density and diversity of fossil assemblages, isotope investigations, species interrelationships including symbiosis and antagonism, lateral and vertical changes in fossil assemblages, zoogeography of fossils, and a final chapter on palæoecological synthesis.

The framework of the book is comprehensive and carefully thought out, and the examples quoted in the subsections give fair coverage of the methods used. Bias towards Mesozoic and Tertiary examples and the brachiopods in particular is evident and is disarmingly admitted by the author. Less explicable is the haphazard presence or absence of commentary on some of the examples. Ma's work on the distribution of fossil corals and their bearing on continental drift, for example, is described, but no warning on the shortcomings of this work is provided for the inexperienced reader. The author stresses the need for a statistical approach to palæontology, yet the record of the orientation of one shell of *Cyrtodonta* in a shale is quoted without comment as evidence of an anchored mode of life.

The importance of transported fossils in palæoecology is minimized and the subject dismissed as being more akin to sedimentology. If the end is merely sedimentological then Dr Ager is right, but it is well to remember that transported fossil assemblages are common and have had a palæoecological history. Sedimentological analysis ought, therefore, to precede palæoecological synthesis and not be an end in itself.

Throughout the book there is an underlying appreciation of the influence that palæoecology must have on systematic palæontology and the species concept, but nowhere does this surface as a major theme. Palæoecologist and systematic palæontologist are in a position to help each other and present a more enlightened image of palæontology. If Dr Ager had developed this theme explicitly he might have more surely strengthened the links between —as he puts it—the impractical theorizers and the old-fashioned museum palæontologists.

The book is well illustrated and attractively presented. Apart from two or three obvious spelling mistakes (Americanized spelling excepted) the only error noted was that of the drawing in Fig 7 3 purporting to represent the trace fossil *Corophioides*. Unusually the book is written in the first person singular (and occasionally plural) which at times intrudes egotistically into the narrative.

Principles of Paleoecology contains much of interest for the specialist and yet can be understood by students with a year's training in geology. Even if the book had not been the first in the field it would have deserved commendation. As it is, Dr Ager is to be congratulated on the successful compilation and condensation of such an enormous field of investigation.

G Y CRAIG

MODERN MICROBIOLOGY

Modern Microbiology

By Wayne W Umbreit. Pp viii+507 (photos and diagrams) (San Francisco and London. W H Freeman and Co , 1962) 48*s*

THIS latest book by Prof Umbreit is a text-book of microbiology which seems to be designed for university students specializing in microbiology—although at no point is this stated by the author. In addition to sections on the structure and physiology of micro-organisms in general there are chapters on pathogenic microbiology (*sic*), brewing, food microbiology, the microbiology of milk products and the use of micro-organisms in the industrial production of solvents, antibiotics and pharmacologically active compounds The treatment of the subject is rather unbalanced in places, for example, the theory, technique and uses of electron microscopy are dealt with in about 300 words along with 2 figures, and bacterial growth factors in about the same space, whereas there are considerable direct quotations from original papers by Gram, Fleming and Florey, together with a long account of the Pasteur/Liebig controversy about fermentation

In a field where good text-books already exist, the value of a new book depends on whether it has a valuable, new approach to the subject or is significantly more up-to date than its predecessors and whether it is accurate Although this book does contain some accounts of recent work, and perhaps has greater emphasis on industrial processes than previous books, these advantages are far outweighed by the many misleading statements, inaccuracies and omissions It is possible to give only a few examples The book contains no account of the glyoxylate cycle while referring readers to reviews (1951–52 vintage) which support the presence of a dicarboxylic acid cycle in bacteria The sections on transformation, transduction and mating (called recombination by the author) are very misleading, and neither the concept of the episome nor the process of lysogenic conversion is mentioned Similarly, the account of bacterial cell walls is completely inaccurate No mention is made of the presence in walls of D-amino-acids, nor of *N*-acetyl glucosamine *N*-acetyl muramic acid is stated to account for all the amino sugar of the wall and is given a structure (p 69) which is completely incorrect In the section on antibiotics no mention is made of the cephalosporins, and most penicillin-resistant staphylococci are incorrectly stated to be resistant by reason of some unknown mechanism rather than by the possession of penicillinase

The book is full of confusing argument—for example " . any present evidence for a nucleus in bacteria must of necessity be somewhat indirect First, bacteria possess DNA Second, bacteria do possess hereditary character Hence, even though we may be unable to see a nucleus there is no doubt but that a nucleus does exist" The style of the book is repetitious and chatty, and large passages in the book give the impression of being direct transcriptions of tape-recorded lectures

M H RICHMOND

BIOLOGICAL EFFECTS OF IONIZING RADIATIONS

The Initial Effects of Ionizing Radiations on Cells

A Symposium held in Moscow, October, 1960, supported by UNESCO and the IAEA, and sponsored by the Academy of Sciences of the U S S R Edited by R J C Harris Pp xii+367 (London Academic Press, Inc (London), Ltd , New York Academic Press, Inc , 1961) 75*s*

THIS volume is a report of a symposium held in Moscow in 1960, and was published in 1961 That it is reviewed at this late date is due mainly to the timeliness of the subject matter

Radiobiology has in its brief existence already reached the stage at which the volume of literature produced, the inter-disciplinary nature of the subject, and the single-mindedness of its research workers make it essential that attention should be directed again to work which has already been done and to theories which have already been postulated In the collected papers of the symposium, beginning and ending with stimulating papers by Alexander and Bacq, ideas are put forward on the role of nuclear as opposed to cytoplasmic sites for the initial lesion of radiation injury, on the relative roles of injury and repair, on the ubiquitous role of oxygen in radiation lesions, and the systems in which oxygen seems to play little or no part There emerges a pattern of biological response to even smaller doses, especially in relation to neuromuscular response The work on the central nervous system is described by the Soviet workers in more detail and allowing for a better assessment than was possible from the Geneva conference on "The Peaceful Uses of Atomic Energy" in 1958 Enough detail is given here to trigger off a full-scale study of this sort of functional response to radiation damage, which is inevitably going to be a more sensitive indication than morphological changes at present used as the main criterion of damage Increasing investigations of functional derangements in systems by radiation exposure may well lead to a change in our concept of radiation sensitivity

The presentation of the papers and discussion in the volume are good, misprints should be unnecessary in a book which has taken this long to produce An interesting aspect of the discussion is a complete lack of East–West division, even when such controversial subjects as the genetic effects of radiation and their relation to dose and dose-rate, or the role of the nervous system in radiation injury are discussed

Looking through the list of contributors to the volume, one is impressed at the galaxy assembled between the covers These people give evidence of their thoroughness, originality and stimulation in the presentations and discussions—and most of them have maintained their promise since Perhaps it is not a bad thing to review a book several years after its appearance, when it can be seen in perspective as a brick which has helped to build up the subject in subsequent years PATRICIA J LINDOP

A RUSSIAN VIEW OF FERRITES AT MICROWAVE FREQUENCIES

Ferrites at Microwave Frequencies

By A G Gurevich Authorized translation from the Russian by A Tybulewicz Pp viii+332 (London Heywood and Co , Ltd , 1963) 140*s*

A STUDY of ferrites at microwave frequencies was first initiated about thirteen years ago The material treated in this work covers the first nine years of this period, which includes part of a very progressive period between 1954 and 1961 Interest in ferrimagnetics at microwave frequencies can conveniently be divided into two main areas a study of the principles and properties of microwave devices and a study of the physical behaviour of ferrimagnetics The author and his colleagues have made very significant contributions to the latter field and it is, therefore, not surprising that the most informative sections of the book are those concerned with physical processes There is comparatively little information on devices, and the book will have only a slight appeal to the microwave engineer Unfortunately, a complementary Russian work dealing with devices has not so far been translated

The work is in three parts dealing, in effect, with magnetic properties of ferrites, wave-guides containing ferrites and non-linear processes It is assumed in the first section that the reader is already familiar with the origin of magnetism in ferrites The statement that "Ferromagnetic resonance can be explained quite simply on the basis of quantum mechanics" is perhaps somewhat terse By compensation, the treatment of spin waves is very well presented, and included is a useful survey of Walker's theory of magnetostatic modes The title of the first chapter "Isotropic Ferrites Magnetized to Saturation" is perhaps somewhat misleading A magnetized ferrite exhibits an anisotropic permeability, and the author is actually referring to the absence of crystalline anisotropy when he states that the medium is isotropic. The phenomena of ferromagnetic resonance is very adequately discussed and, in this section especially, the author has referred primarily to Russian sources for experimental data.

Although the sections on electromagnetic wave propagation in infinite ferrite media and waveguides containing ferrite have been carefully prepared it is in this area that the book is weakest. The author appears to have overlooked completely any British contributions to this field and there is only one figure showing results for circular waveguides. The rectangular waveguide containing a transversely magnetized ferrite slab has been treated more fully and the author presents the results of his own computations. There is no discussion of the junction circulator configuration which forms the basis of an important class of ferrite components.

As previously mentioned, the book does not describe devices, and it is only likely to prove helpful in this area to the microwave engineer who is already fully conversant with the factors which affect the design of waveguide ferrite components.

In the final section on non-linear processes, the author draws more on work from the United States than elsewhere in the book. A very readable review of work until 1959 is presented. Unfortunately, many very interesting developments have occurred since that time of which the study of longitudinal pump instabilities and magnetoacoustic interactions are, perhaps, the most significant.

In conclusion, the book can be very warmly recommended to those who are interested in studying an approach to microwave ferrimagnetics which is not based primarily on Western literature. The numerous references to Russian results are of particular value since this information is often not readily available to Western readers. The text was published as part of a series on the physics of semiconductors and semiconductor devices, and it is to be hoped that a treatment of Russian studies in this field, after 1959, will become available within the next few years and without such a long delay in translation.

P. J. B. Clarricoats

QUANTUM BIOCHEMISTRY

Quantum Biochemistry

By Prof. Bernard Pullman and Alberte Pullman. Pp. xvi+867. (New York and London: Interscience Publishers, a division of John Wiley and Sons, 1963.) 195s.

"WHEN I use a word", Humpty-Dumpty said in a rather scornful tone, "it means just what I choose it to mean—neither more nor less". The Pullmans have much the same attitude to the words 'quantum biochemistry', by which they evidently mean the calculation, using traditional quantum-mechanical methods, of charge distributions and associated parameters in organic molecules. Most of the book is, in fact, an edited collection of their previous publications, little or no interest being shown in other workers' results, in newer and more sophisticated calculations or in actual measurements, for example, of electron donor and acceptor properties of molecules. Classical experiments on quantum yields in photosynthesis and photodissociation of carbon monoxide complexes with hæm, initiated in Warburg's laboratory thirty years ago and since extended with most valuable results, are not even mentioned. Metal ions and their complexes are referred to only incidentally, and no account is given of experiments carried out by nuclear magnetic resonance and other techniques which have helped to clarify the role of such ions in enzymatic reactions. These contributions, among many others, are important to the development of a quantum biochemistry. The term itself perhaps has a limited usefulness, since it is surely not being too optimistic to believe that all biochemical reactions must in the last analysis be interpreted according to some quantum-mechanical scheme.

Quantum Biochemistry is a personal catechism and can be judged as such. A general introduction outlines quantum mechanics and methods, but it is difficult to imagine that more than a small minority of biochemists will be able to follow the arguments. Those who can, will already be familiar with more acceptable treatments such as are found in Coulson's *Valence*, Kauzmann's *Quantum Chemistry* and Streitweiser's *Molecular Orbital Theory*. The Pullmans' account is often dated: the discussion of bond-lengths and bond-orders, illustrating the value of molecular orbital calculations of the ground-state of aromatic hydrocarbons, is based on data at least ten years old. It is disappointing to find no proper discussion of self-consistent field molecular orbital methods. Biochemists who do follow the introductory chapters may be misled by the discussion of l and m_l quantum numbers (p. 17) and, for example, by the discussion of the bond-angles in water (p. 59), it is now generally accepted that hydrogen–hydrogen repulsions are insufficient to account for the observed bond-angle of 106° or so, the deviation from perfect tetrahedral symmetry being more satisfactorily explained by the use of oxygen hybrid orbitals rather than pure '*p*' orbitals, lone-pair-bonding-pair repulsions decreasing the H—O—H angle by several degrees.

There is no doubt that the compilation of calculations of charge distribution in series of molecules occurring in biological systems is of interest, even if it is clear that they will, in many cases, require considerable revision. Thus, it has already been shown experimentally that the electron-donor properties of chlorpromazine and the electron-accepting behaviour of the tropylium and pyridinium ions are quite different from those anticipated by elementary molecular orbital theory. In reading this book one might not appreciate that one of the major tasks of the next decade will be that of relating the electronic properties of molecules to their biological activity, using more rigorous theoretical methods based on a more complete understanding of the underlying biochemical reaction mechanisms. One should recognize that in many instances the successful application of quantum mechanics to biochemistry is held up not by the lack of theoretical equipment but rather by a complete absence of information on what one should be calculating. The final discussion leads to the conclusion of "the essential importance of molecular systems with mobile electrons, and, therefore, of electronic de-localization, in the phenomena of life": an unobjectionable sentiment perhaps, but one that has often been expressed. At this point the reader is left with a strong *déjà* sensation: as the Walrus said, "It seems a shame to play them such a trick, after we've brought them out so far, and made them trot so quick".

The Pullmans deserve great credit for having been among the first to recognize the possible importance of electron density distributions and π-electrons in biological systems. This book, while usefully summarizing their views, also indicates that they do not appear to recognize consistently the limitations in their approach, even at the theoretical level. Alternative approaches are dismissed far too lightly, and this must be regretted since these calculations do not solve many biochemical problems, rather do they indicate the direction along which lines of enquiry might be profitable. The Pullmans have written some of the first words about the electronic properties of biological molecules—indeed, many of the first words—but what they have to say is certainly not the last word on the subject.

R. Mason

Generalised Electrodynamics and the Structure of Matter

By [the late] Prof. S. R. Milner. Edited by Dr. C. W. Kilmister. Pp. ii + 290. (Sheffield: The University Library, 1963.) 42*s*.

SIR MILNER'S posthumous papers contained a rich collection of results of his investigations in three closely allied fields. There was, first, an algebraical technique which arose, for Milner, in his attempts to elucidate Eddington's later work, though it has no necessary connexion with it. This technique made it possible for Milner to operate conveniently with Clifford algebras (for example, quaternions, Dirac matrices) and to seek different criteria for what constitutes a simple system. This was then useful to him in the second kind of investigation—that into the generalized electromagnetic theory. Here Milner used his algebraic tools to suggest an extremely natural and straightforward generalization of Maxwell's equations, which leaves electromagnetic theory exactly the same, away from charge, but modifies the equations in charge in such a way that the classical electron model becomes a possible stable configuration, without additional forces to hold it together. The more detailed investigations of this kind led him on to considering general relativity, and in this field he sought to re-express the existing theory of gravitation in a way that was more directly connected with ideas of mass, energy and force.

These papers have now been collected together and edited by Dr. C. W. Kilmister, King's College, University of London, who has added a number of notes relating the new notations of Milner to more commonly used ones.

Mass and Abundance Tables for Use in Mass Spectroscopy

By Dr. J. H. Beynon and A. E. Williams. Pp. xxi + 570. (Amsterdam and London: Elsevier Publishing Company, 1963.) 80*s*.

THERE is little one can say in a review of this set of tables except that it is a must for all workers interested in the determination of molecular weights and molecular structure of organic compounds. This is especially true of those who are working in the field of high-resolution mass spectrometry, in which area a molecular weight determination leads directly to the molecular formula. After an introduction in English, German, French and Russian, the book lists under the appropriate mass numbers (*a*) the atomic composition, (*b*) the molecular mass (^{12}C = 12·000000), (*c*) 100 P_{m+1}/P_m, (*d*) 1,000 P_{m+2}/P_m, (*e*) P_{m+1}/P_{m+2}, where P_{m+i} is the height of the (parent + *i*) isotopic peak. On the carbon-12 scale, some of the molecular weights fall below the mass number, and this must be remembered when using the tables. Thus under mass 319, there is the entry for $C_{14}HN_5O_5$, 0·997764. This refers to 318·997764.

As has been said before, this book will be invaluable, especially for workers in the relatively new field of the high-resolution mass spectrometry of organic compounds.

A. MACCOLL

Flows in Networks

By L. R. Ford, jun., and D. R. Fulkerson. Pp. xii + 194. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1963.) 48*s*. net.

THE most familiar example of a network flow problem is that defined by Kirchoff's laws for the flow of an electric current in a network of resistors. In this problem a certain quadratic function of the current representing the heat dissipated has to be minimized subject to linear constraints. This is an example of the kind of problem more complicated than that considered in *Flows in Networks*, where the attention is limited to corresponding problems in which linear functions are minimized, and the further restriction is adopted that the assumption of integral data provides the existence of an integral solution. It is, then, an introduction to the wide and rapidly developing field loosely classified under the name of linear programming, which has come to the fore in recent times.

It should not be thought, however, that the application of the ideas of the book is in some narrowly restricted field concerned primarily with the transport of petrol across deserts. The subjects discussed by the authors range from such practical ones as the way across deserts, to the extremely theoretical questions in graph theory, the theory of partially ordered sets, and the theory defined by matrices, the elements of which are 0 and 1. In all cases a great deal of attention is directed to finding effective procedure which will enable the actual calculation of a solution to be carried out. The book is divided into four chapters, in which the first forms a necessary introduction to each of the others. These last three discuss, respectively, combinatorial applications, minimal cost flow problems, and multiterminal maximal flows.

There is a great deal in the book which is not available elsewhere except in the original papers, and much of the work is in fact due to the authors themselves in the past few years. The book is well produced, and should provide a means of linking workers in the (at present) separated fields of operations research, communications engineering, and combinatorial mathematics.

C. W. KILMISTER

Recent Advances in Allergy Research

Edited by F. Hahn, P. Kallós and G. B. West. (Transactions of the Collegium Internationale Allergologicum, Fifth Symposium in Freiburg i. Br., October 1962.) Published simultaneously as Vol. 22, Nos. 2, 3, 4, 5 and 6 (1963), *International Archives of Allergy and Applied Immunology*. Pp. iv + 355. (Basle and New York: S. Karger, 1963.) 55 Sw. francs; 55 D.M.

THIS book contains 34 of the 39 scientific papers given at the fifth symposium of the Collegium Internationale Allergologicum in Freiburg. Because of the wide range of topics covered and the fact that the papers were given by many different groups of research workers, such as physiologists, pharmacologists, biochemists, allergists and clinicians, the reader is given a very good insight into the present trends of research into allergy. As we still do not understand the underlying causes of the symptoms seen in allergic reactions many papers are devoted to the compounds which may produce these symptoms. At one time the symptoms of allergy were thought to be due to histamine, but recently many other substances have become associated with allergy. This aspect of research is reflected in the many papers dealing with the origin, storage, metabolism and role of histamine, together with papers on some of the other substances believed to be involved including the kinins and a much newer set of substances, the neuraminyl glycosides.

Several papers deal with the diagnostic aspects of the causes of allergy. It is interesting to read that the skin-sensitivity test can give erroneous results and that a bronchial test for asthmatic allergy is more informative. Another group of papers deals with the relationships of collagen diseases and allergy. There is a good review of the dermatological aspect of the collagen diseases and also a paper on the similarity between collagen diseases and the effects of experimentally implanted fibrin in connective tissues. There is a good historical review of the changes which have occurred in the medical concepts of allergy, and this includes an excellent bibliography. Among the many other subjects discussed are anaphylotoxin, penicillin allergy, precipitins to moulds in asthmatic sera and allergic reactions in blood.

A few papers tend to be rather brief, but on the whole this book keeps the reader who is interested in a better understanding of the causes of allergy abreast of the latest trends in allergy research.

N. G. WATON

THE 'M.R.C.' FIFTY YEARS AGO AND NOW

By DR. P. B. MEDAWAR, F.R.S.
Director, National Institute for Medical Research, London, N.W.7

IN Great Britain the support of medical research on a national scale began just fifty years ago, as a by-product of the National Health Insurance Scheme which Lloyd George had launched two years beforehand, in 1911. The regulations which brought a Medical Research Fund into being called for the setting up of a small independent Medical Research Committee, consisting mainly but not entirely of 'scientific experts', to advise the Minister in charge of national insurance on how the Fund should be spent. The size of the Fund itself was determined by a capitation fee of one penny for each insured person in the United Kingdom, and the sum available to the Committee in its first year was £55,000—the equivalent of perhaps £300,000 to-day.

The arrangement made sense, for its sponsors had urged that the Fund, itself a form of insurance, would ultimately lighten the nation's burden of care for the sick and disabled. In practice it turned out to be a bad bargain, for when war broke out in 1914 and insured persons entered the armed forces they ceased to be classified as such. The sum allotted to medical research thus inevitably declined—a fact to which the Committee directed attention in language more temperate ("The Committee venture to hope . . .", etc.) than might be used in the same circumstances to-day. Inflation made matters worse, and by the time it came to write its fifth annual report the Committee declared that the funds available to it were inadequate to support the research it had already put in hand.

After the War the Government's support of medical research was put on a new administrative basis. All the departments and boards which had to do with matters of health were brought together under a single Ministry of Health, but in a famous memorandum Dr. Christopher Addison, M.P., then speaking as Minister of Reconstruction, urged that it would be unwise for the Committee to come under the new Minister's charge. (Addison himself later became the first Minister of Health.) In 1920, therefore, the Committee became the Medical Research Council, with its own Charter, and with the right to determine its own policy and to dispose of the funds allotted to it as it thought best. Administratively, the Council is not a Government Department (and its employees are not Civil Servants), it is under a ministerial committee of the Privy Council whose chairman, now the Minister for Science, answers to Parliament for the Council's work. Though the business it now transacts has multiplied enormously, the Council is still a small body: its Constitution limits it to twelve members, of whom nine are scientists or clinicians and two others are members of, respectively, the House of Commons and the House of Lords. The Council receives an annual grant from the Treasury, to-day of about six million pounds—and unlike the exiguous funds administered by the old Committee, it shows no signs of diminishing year by year.

The Committee's metamorphosis into a Council was in no sense a criticism of its work. On the contrary, the transformation was intended to make sure that its independence and power to take the initiative were not overborne by departmental pressures in the difficult and harassing days of reconstruction. The Committee was, in fact, a brilliant success, and now that we can weigh up their consequences its actions and intentions seem quite remarkable in their prescience and good sense. At this distance of time it is scarcely possible to distinguish individual contributions to its counsels, but though Addison must be given most of the credit for the Committee's highly effective administrative structure we may suspect that Walter Morley Fletcher, the first secretary—there have been only three in all—had most to do with devising the Committee's scientific policy.

The Committee intended from the outset to support research, both centrally, in a research institute manned by its own scientific staff, and peripherally, by way of grants to help research workers in universities and elsewhere. Anyone might be supported whose work gave promise "of being co-ordinated within a general scheme for the organized advancement of medical knowledge". The Committee soon found it necessary to set up "special committees for special purposes", by this means bringing together scientists who in those days worked very much more on their own than they do now.

In its fifth report at the end of the First World War, the Committee took stock of its progress and of the likely future of medical research. In its first report it had spoken almost with awe of "the duty laid upon them of wielding the new and potent instrument" which had been "placed in their hands by the State", but what it had to say now was peremptory and to the point. "Our countrymen must decide whether they are to encourage and maintain" a medical research service or not. If so, it would no longer do for medical research to be pursued as a private hobby by the well-to-do or in time stolen with difficulty from routine duties. Its practitioners must enjoy "reasonable financial security, given directly for research work and not for something else". Above all, the foundations of medical research must be laid in science: "the important attainments of new knowledge come from disinterested enquiry followed under the spur of free intellectual impulse, rather than from frontal attacks made in a utilitarian spirit upon problems of immediate practical interest". Indeed, "there is . . . a real danger lest the insistent calls given by disease and suffering for immediate relief should actually delay progress by attracting scientific effort along the wrong paths". This was a very weighty declaration: at the end of an utterly destructive War during which it had to face the agony of insistent and immediate medical demands, the Committee was better placed than anybody before or since to put a just value on the merits of the pragmatic or directly utilitarian approach to medical science. At all events, the declaration became and remained one of the canons of the Council's policy—became part, indeed, of the great unwritten charter of academic freedom. It is a charter which we should not come to think of as beyond all criticism in all its clauses: some yielding to social, economic and rudely utilitarian pressures there must be, but no one has yet succeeded in drafting a clause in suitably abstract language which gives them their due, and not more than their due, weight.

The Committee's Central Research Institute remained for five years a purely notional body, for war broke out before it could take up residence in Mount Vernon Hospital in Hampstead. (Mount Vernon remained a hospital, eventually a hospital for the Royal Flying Corps.) With the end of the war the building was regained and occupied by what (with the grant of a charter) could now be called a National Institute for Medical Research, and it still houses two large and important divisions of the Institute. By the mid-'thirties it became clear that the Institute would have to be housed in larger premises, which the Council decided to build anew on an estate already in its possession at Mill Hill. Unfortunately, the attempt to house the Institute in suitable quarters was again held up by a World War: the building was taken over by the Admiralty, and final occupation was delayed until 1950.

The original design of the Central Research Institute provided for five divisions under five heads of great distinction bacteriology, under Almroth Wright, biochemistry and pharmacology under Henry Dale (who became first director of the National Institute and first won it an international reputation), applied physiology, under Leonard Hill, a department of medical statistics, under John Brownlee, and a department of clinical research, under Thomas Lewis, which can be thought of as the larval form of the Council's future Clinical Research Centre at Northwick Park Among its extra-mural enterprises, it is noteworthy that biological standardization, originally under Georges Dreyer at Oxford, was one of the Council's very earliest concerns To-day the standardization and control of biological agents is one of the Council's statutory responsibilities, and it has long been discharged within the National Institute itself The Institute has from the outset been a many-sided organization, as the great variety of its activities makes clear At this moment the matters under investigation extend from the adaptation of human beings under thermal stress to the nature of a volatile hormone manufactured by queen bees, and from the growth of leprosy bacilli to the measurement of the concentration of alcohol in the blood The consolidation of the Institute into one genuinely organic whole was above all the work of its second director, C. R Harington The Institute's resident scientific staff now numbers about 120, and it receives many guests from overseas who stay for a year or more

With the growth and deployment of medical science no one institute could hope to accommodate all its practitioners, and from time to time the Council has therefore set up research units—groups of scientists brought together for a more particular common purpose than the advancement of basic medical research as a whole There are about 80 research units and groups, some large and world famous, but some—a kindly observer might say—merely world famous A list of these units and groups is given at the end of this article Among the largest are the Units for Radiobiological Research at Harwell and for Molecular Biology at Cambridge—both founded in 1947 during the tenure of office of the second secretary, Edward Mellanby, who unfortunately did not live to see how rich was to be the scientific harvest of the biophysical research which he took such pains to cultivate A rough (and to some small extent overlapping) classification of the activities of the groups and units shows that about a dozen are predominantly concerned with clinical problems, about a dozen with problems of psychology and of mental illness, and no less than ten (counting part of the Radiobiology Unit) with one form or another of genetics (No one could say now what one far-seeing critic said in 1914—that the Committee gave no recognition to the study of heredity) Environmental, social and industrial medicine account for 10, radiobiology in all its aspects for 7, microbiology for 8, special senses for 5, tropical medicine for 5, nutritional matters for 4 There is no simple interpretation of these figures the distribution of subjects depends partly on their intrinsic scientific value, partly on social urgency, and partly on the extent to which they are in need of special care and protection—itself a function of the degree to which they may have been neglected by the universities The Council aims primarily at the support of men and ideas, many of the groups and units have grown up around and on the initiative of individual scientists of great ability, and often dissolve when their head retires Only the largest units housed in their own premises are permanently established With limited funds it is clear that no research council would have room to manœuvre if it were to commit its entire income to permanently recurrent subsidies The Council's total staff now numbers 2,931, of whom 788 are scientifically qualified It is a sign of the times that, of these 788, only about 30 per cent have medical degrees

The support of groups and units is not all the Council does to subsidize medical research, for its funds contribute largely to the maintenance of the Institute of Cancer Research (including the Chester Beatty Institute) and the Strangeways Research Laboratory The Council maintains an external staff, appoints research fellows and scholars, and supports many promising research schemes by monetary grants Beyond all these enterprises, the Council has in very recent years undertaken the complex and immensely important task of "promoting and co-ordinating medical research in the tropics, in so far as this directly or indirectly concerns this country" (the qualifying clause is interpreted in a wide and humane sense) By and large, then, the Council's activities span the whole spectrum of modern medical research The Council's task has been growing in size and complexity, but in terms of any of the 'objective' standards which can be applied on these occasions it is one that has been successfully discharged The records of the research it has sponsored show that the M R C has indeed created situations conducive to the growth and development of medical science

M R C RESEARCH ESTABLISHMENTS

Date of establishment	Title of Unit	Address	Director
(1915)	National Institute for Medical Research	The Ridgeway, Mill Hill, London, N W 7	Dr P B Medawar, F R S
(Projected)	Clinical Research Centre	c/o M R C Clinical Research Centre Planning Office, Medical School, The University, Birmingham 15	Prof J R Squire
(1958)	Unit for Research on Occupational Aspects of Ageing	University Department of Psychology, Abercromby Square, Liverpool 7	Prof L S Hearnshaw (*honorary*)
(1955)	Air Pollution Research Unit	The Medical College of St Bartholomew's Hospital, Charterhouse Square, London, E C 1	Dr P J Lawther
(1962)	Atheroma Research Unit	Western Infirmary, Glasgow, W 1	Dr B Bronte-Stewart
(1955)	Unit for the Experimental Investigation of Behaviour	Department of Psychology, University College, Gower Street, London W C 1	Prof G C Drew (*honorary*)
(1947)	Biophysics Research Unit	26–29 Drury Lane, London, W C 2	Sir John Randall, F R S
(1959)	Blood Coagulation Research Unit	Churchill Hospital, Oxford	Dr R G Macfarlane, F R S
(*)	Blood Group Reference Laboratory	Gatliff Rd , off Ebury Bridge Rd , London, S W 1	Dr A E Mourant
(1946)	Blood Group Research Unit	Lister Institute, Chelsea Bridge Rd , London, S W 1	Dr R R Race, F R S
(1954)	Body Temperature Research Unit	Department of the Regius Professor of Medicine, Radcliffe Infirmary, Oxford	Sir George Pickering, F R S (*honorary*)
(1959)	Bone-seeking Isotopes Research Unit	Churchill Hospital, Oxford	Dame Janet Vaughan (*honorary*)
(1956)	Carcinogenic Substances Research Unit	Washington Singer Laboratories, The University, Exeter	Sir James Cook, F R S (*honorary*)
(1945)	Cell Metabolism Research Unit	Department of Biochemistry, Oxford	Sir Hans Krebs, F R S (*honorary*)

*Administered since April 1950 by the Council for the Ministry of Health

M R C Research Establishments

Date of establishment	Title of Unit	Address	Director
(1963)	Cellular Immunology Research Unit	Sir William Dunn School of Pathology, University of Oxford	Prof J L Gowans (*honorary*)
(1962)	Chemotherapy Research Unit	Molteno Institute, Downing Street, Cambridge	Dr Ann Bishop, F R S
(1919)	Department of Clinical Research	University College Hospital Medical School, London, W C 1	Dr E E Pochin
(1962)	Cyclotron Unit	Hammersmith Hospital, Ducane Rd , London, W 12	D D Vonberg
(1949)	Wernher Research Unit on Deafness	King's College Hospital Medical School, Denmark Hill, London, S E 5	Dr T S Littler
(1961)	Dental Research Unit	Dental School, Lower Maudlin Street, Bristol 1	Prof A I Darling (*honorary*)
(1946)	Clinical Endocrinology Research Unit	2 Forrest Road, Edinburgh 1	Dr J A Loraine
(1962)	Unit for the Study of Environmental Factors in Mental and Physical Illness	London School of Economics, Aldwych, London, W C 2	Dr J W B Douglas
(1962)	Epidemiological Research Unit (Jamaica)	University of the West Indies, Mona, Kingston 7, Jamaica	Dr W E Miall
(1960)	Epidemiological Research Unit (South Wales)	4 Richmond Road, Cardiff	Prof A L Cochrane (*honorary*)
(1945)	Department of Experimental Medicine	Tennis Court Rd , and 5 Shaftesbury Rd , Cambridge	Prof R A McCance F R S
(1953)	M R C Laboratories, Gambia	Fajara, near Bathurst, Gambia, British West Africa	Dr I A McGregor
(1961)	Gastroenterology Research Unit	Central Middlesex Hospital, Park Royal, London, N W 10	Dr E N Rowlands
(1957)	Clinical Genetics Research Unit	Institute of Child Health, Hospital for Sick Children, Great Ormond Street, London, W C 1	Dr J A Fraser Roberts, F R S
(1955)	Experimental Genetics Research Unit	University College, Gower Street, London, W C 1	Prof H Gruneberg, F R S (*honorary*)
(1962)	Human Biochemical Genetics Research Unit	Department of Biochemistry, King's College, Strand, London, W C 2	Prof H Harris (*honorary*)
(1957)	Microbial Genetics Research Unit	Hammersmith Hospital, Ducane Rd , London, W 12	Dr W Hayes
(1958)	Population Genetics Research Unit	Old Road, Oxford	Dr A C Stevenson
(1959)	Psychiatric Genetics Research Unit	Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S E 5	Dr E T O Slater
(1946)	Experimental Hæmatology Research Unit	Wright-Fleming Institute of Microbiology, St Mary's Hospital Medical School, London, W 2	Prof P L Mollison
(1963)	Abnormal Hæmoglobin Research Unit	Department of Chemical Pathology, St Bartholomew's Hospital, E C 1	Dr H Lehmann (*honorary*)
(1952)	Industrial Injuries and Burns Research Unit	Birmingham Accident Hospital, Bath Row, Birmingham 15	Dr J P Bull
(1947)	Laboratory Animals Centre	M R C Laboratories, Woodmansterne Road, Carshalton, Surrey	Dr W Lane-Petter
(1953)	Infantile Malnutrition Research Unit	Mulago Hospital, Kampala, Uganda	Prof R F A Dean
(1960)	Unit for Research on the Chemical Pathology of Mental Disorders	Department of Physiology, The Medical School, Birmingham 15	Prof I E Bush (*honorary*)
(1957)	Metabolic Disturbances in Surgery Research Unit	Department of Urology, The General Infirmary, Leeds 1	Prof L N Pyrah (*honorary*)
(From October 1964)	Metabolic Reactions Research Unit	Imperial College of Science and Technology, London, S W 7	Prof E B Chain, F R S (*honorary*)
(1947)	Laboratory of Molecular Biology	University Postgraduate Medical School, Hills Road, Cambridge	Dr M F Perutz, F R S
(1958)	Mutagenesis Research Unit	Institute of Animal Genetics, West Mains Road, Edinburgh	Dr Charlotte Auerbach, F R S (*honorary*)
(1962)	Neuroendocrinology Research Unit	Department of Human Anatomy, South Parks Road, Oxford	Prof G W Harris, F R S (*honorary*)
(1958)	Neuropharmacology Research Unit	Department of Experimental Neuropharmacology, The Medical School, Birmingham 15	Dr P B Bradley (*honorary*)
(1957)	Neuropsychiatric Research Unit	M R C Laboratories, Woodmansterne Rd , Carshalton, Surrey	Dr D Richter
(1944)	Human Nutrition Research Unit	Nutrition Building, National Institute for Medical Research, The Ridgeway, Mill Hill, N W 7	Prof B S Platt
(1926)	Dunn Nutritional Laboratory	Milton Road, Cambridge	Dr E Kodicek
(1955)	Obstetric Medicine Research Unit	University of Aberdeen Medical School	Sir Dugald Baird (*honorary*)
(1954)	Wernher Research Unit on Ophthalmological Genetics	Royal College of Surgeons of England, Lincoln's Inn Fields, London, W C 2	Prof A Sorsby (*honorary*)
(1944)	Otological Research Unit	National Hospital for Nervous Diseases, Queen Square, London, W C 1	Dr C S Hallpike, F R S
(1948)	Environmental Physiology Research Unit	London School of Hygiene and Tropical Medicine, Keppel Street (Gower Street), London, W C 1	Dr J S Weiner
(1945)	Pneumoconiosis Research Unit	Llandough Hospital, Penarth, Glamorgan	Dr J C Gilson
(1960)	Unit for Research on the Epidemiology of Psychiatric Illness	Department of Psychological Medicine, University of Edinburgh	Prof G M Carstairs (*honorary*)

(1947)	Radiobiological Research Unit	Harwell, Didcot, Berks	Dr J F Loutit, F R S
(1953)	Radiological Protection Service	Clifton Avenue, Belmont, Sutton, Surrey	W Binks
(1953)	Experimental Radiopathology Research Unit	Hammersmith Hospital, Ducane Road, London, W 12	Miss Tikvah Alper
(1958)	Rheumatism Research Unit	Canadian Red Cross Memorial Hospital, Taplow, Maidenhead	Prof E G L Bywaters (*honorary*)
(1952)	Unit for Research on the Experimental Pathology of the Skin	The Medical School, Birmingham 15	Dr C N D Cruickshank
(1948)	Social Medicine Research Unit	The London Hospital Research Laboratories, Ashfield Street, London, E 1	Prof J N Morris
(1926)	Statistical Research Unit	University College Hospital Medical School, 115 Gower Street, London, W C 1	Dr W R S Doll
(1947)	Toxicology Research Unit	M R C Laboratories, Woodmansterne Road, Carshalton, Surrey	Dr J M Barnes
(1956)	Trachoma Research Unit	Lister Institute of Preventive Medicine, London, S W 1, and M R C Laboratories, Gambia	Dr L H Collier (*honorary*)
(1955)	Tropical Metabolism Research Unit	University of the West Indies, Mona, Kingston 7, Jamaica	Prof J C Waterlow
(1948)	Tuberculosis Research Unit	M R C Laboratories, Holly Hill, Hampstead, London, N W 3	Dr P M D'Arcy Hart
(1956)	Unit for Research on Drug Sensitivity in Tuberculosis	Postgraduate Medical School of London, Ducane Road, London, W 12	D A Mitchison (*honorary*)
(1955)	Virus Research Unit	M R C Laboratories, Woodmansterne Road, Carshalton, Surrey	Dr F Kingsley Sanders
(1959)	Experimental Virus Research Unit	Institute of Virology, Church St, Glasgow, W 1	Prof M G P Stoker (*honorary*)
(1962)	Vision Research Unit	Institute of Ophthalmology, Judd St, London, W C 1	Dr H J A Dartnall

M R C Research Groups

Date of establishment	Title of Group	Address	Director
(1960)	Research Group in Enzymology	Department of Chemical Pathology, St Mary's Hospital Medical School, London, W 2	Prof A Neuberger, F R S
(1960)	Research Group on Adrenergic Mechanisms	University Laboratory of Physiology, Oxford	Sir Lindor Brown, F R S
(1960)	Clinical Immunology Research Group	Institute of Diseases of the Chest, Brompton Hospital, London, S W 3	Dr J Pepys
(1961)	Research Group on Experimental and Clinical Problems of Transplantation	Department of Surgical Science, University of Edinburgh	Prof M F A Woodruff
(1961)	Research Group on the Organization of Central Mechanisms Subserving Vision	Department of Physiology, University Medical School, Edinburgh	Prof D Whitteridge, F R S
(1961)	Cardiovascular Research Group	Postgraduate Medical School of London, Ducane Road, London, W 12	Dr J P Shillingford
(1961)	Research Group on Demyelinating Diseases	13 Framlington Place, Newcastle upon Tyne 2	Dr E J Field
(1962)	Research Group on the Relation of Functional to Organic Psychiatric Illness	Department of Psychological Medicine, Queen Victoria Road, Newcastle upon Tyne 1	Prof M Roth
(1962)	Epigenetics Research Group	Institute of Animal Genetics, University of Edinburgh	Prof C H Waddington, F R S
(1963)	Research Group on Respiration and Energy Metabolism in the Newborn	London Hospital Medical College, Turner Street, London, E 1	Prof K W Cross
(1963)	Biomechanics Research Group	Royal College of Science and Technology, George Street, Glasgow C 1	Prof R M Kenedi
(1963)	Research Group on the Immunological Aspects of Dermatology	Institute of Dermatology, Lisle Street, London, W C 2	Dr J L Turk
(1963)	Research Group on Genetic Problems in Orthopædic Disease	Department of Orthopædic Surgery, University Medical School, Edinburgh	Prof J I P James
(1963)	Research Group for the Study of Megaloblastic Anæmias	Postgraduate Medical School of London, Ducane Road, London, W 12	Dr D L Mollin

PROGRESS OF CANCER RESEARCH

THE fortieth annual (1962) report of the British Empire Cancer Campaign* is a weighty volume of nearly 700 pages, the titles of papers published by the research workers financed wholly or in part by the Campaign, or who work in centres affiliated to the Campaign, numbered nearly 900 in 1962 (almost a third of this huge total came from the Institute of Cancer Research, London) As in previous reviews, the material of the report will be divided into three main groups and treated by three reviewers "Carcinogenesis and the Biology of Cancer Generally" (I H), "Radiobiology, Radiotherapeutics and Physics" (P A) and the "Clinico-Pathology of Cancer" (A L L)

It should scarcely be necessary to say that only a fraction of the many interesting research topics can be dealt with, and many must be omitted

Haddow *et al* have continued their investigation of the carcinogenic potency of compounds containing iron, those showing activity were saccharated iron-oxide, ferric-sodium gluconate, ferrous glutamate and iron hydrogenate dextran The interest and importance of these investigations are, of course, that these compounds, or at least substances similar to them, are being used in medical practice as anti-anæmia preparations, and on a large scale

The Fahmys have continued their work on mutagens as carcinogens, in *Drosophila*, they find that calf thymus histone (basic protein) and poly-L-glutamic acid (acid protein) produce small chromosome deletions, but other macromolecules were also effective, for example, polymethacrylic acid (molecular weight about one million)

The failure to show resistance by normal tissue to invasion by cancer tissue has been explained by Green as due to a loss of immunological identity factors, and this idea is given support by the discovery that tumour tissue is lacking in certain of its protein components, the work of the Millers and others on protein changes in azo-dye carcinogenesis in rat livers lends support to Green's hypothesis The main feature of the deletion theory of carcinogenesis, according to Green, is that the transformation consists in the loss of certain specific immunological factors (iso-antigens) which determine the relationship of cells to one another, normal cells are supposed to exhibit identifying iso-antigens, the carcinogen combines with these antigens, the normal tissues react by attempting to destroy the cells presenting the new antigen complex, these cells respond by losing the new antigen which carries with it the identifying iso-antigen, the resulting cells are now free from this antigen and can now invade tissue without being recognized According to this view the cancer cell is deficient in antigenic factors, but fortunately for the outlook for therapy on immunological or chemotherapeutic lines, evidence is now coming to light that cancer cells do in fact contain new antigens not present in normal tissue, and although it would be going too far to say that there are grounds for much optimism, pessimism no longer seems entirely justified In the early years of organized cancer research in the first decade or two of the century, it was found that some immunity to transplantable tumours in mice could be induced by first inoculating the animal with embryonic tissue or with skin But when pure strains of mice became available, this immunity was shown to have been brought about by strain differences rather than by any immunological differentiation between normal and neoplastic tissues Nevertheless, attempts to make use of immunity as an anti-cancer technique has been the aim of countless experiments ever since transplantable tumours became available in the laboratory.

Work at the Westminster Hospital, London, on tissue proteins by electrophoretic analysis has shown that in cancer the composition of the liver is changed, the more basic components are decreased and the more acid components increased Baldwin at Nottingham, in immunological investigations of rat liver cell antigens during azo-dye carcinogenesis, states "Further confirmation of deletion of normal rat liver cell sap antigens from DMAB-induced liver tumour has been obtained from the analysis of rabbit anti-normal liver cell sap antisera pre-absorbed with tumour cell sap Immunoelectrophoresis of absorbed antisera has permitted further resolution of cell sap antigens showing that out of sixteen components, six normal liver antigens were deleted from tumour Following exhaustive absorption of anti-tumour cell sap antiserum with normal liver cell sap, three antigenic components reacting with the tumour fraction were still detectable Hence it is concluded that DMAB-induced liver tumour contains at least three abnormal cell sap antigens which do not cross-react with normal liver . Microsome fractions from DMAB-induced tumour have also been shown to contain abnormal antigens Thus four antigenic components were detectable following agar-gel immunodiffusion analysis of deoxycholate solubilized microsome fractions from liver tumour with anti-tumour microsome antisera, and at least one of these antigens did not cross-react with normal liver microsome fractions Further confirmation that DMAB-induced liver tumour contains abnormal microsomal antigens was obtained from the analysis of anti-tumour microsome antisera pre-absorbed with normal microsomes"

Schild and Dale at University College, London, refer to some of their work as "Anaphylaxis and the Investigation of Specific Tumour Antigens"

Woodruff, at the University of Edinburgh, from an examination of *A* strain mice bearing spontaneous or transplanted mammary carcinoma, concludes that this tumour possesses one or more antigens not present in normal *A* strain tissues, and retains these after transplantation. He now states "Further work (Woodruff and Symes, 1962*b*) has shown that after a certain number of transplant generations, which differs for different tumours, the capacity to evoke splenomegaly is lost and this is attributed to deletion of tumour-specific antigen It is suggested that such deletion may occur also in tumours which are not transplanted but remain sufficiently long in the animal in which they arise

"If this hypothesis is correct it would seem to provide an important clue to the understanding of the behaviour of malignant tumours not only in experimental animals but also in man During the phase of antigenic difference a tumour may conceivably be held in check, or even destroyed, by immunological mechanisms, whereas after deletion of all tumour specific antigens the natural immunological defences have no *point d'appui* and any restraining effect they may have is lost "

Tissue culture has rapidly become an important laboratory technique in cancer more than twenty different investigations using the *in vitro* method are described in the report, for example, cultures of tumour cells are being used as test-tube material for assessing the cytostatic effect of drugs used in the chemotherapy of cancer Wylie and Easty state "The most consistent success has been obtained in growing various gliomata, including astrocytomata, medulloblastomata and ependymomata.

---

* British Empire Cancer Campaign Fortieth Annual Report covering the year 1962 Part 1 The Chairman's Statement and the Accounts of the Central Organization Pp xxxviii Part 2 The Scientific Report of the Researches undertaken by the Central Organization and its Autonomous Councils in the United Kingdom and by some of its Affiliated Organizations Overseas Pp xxxix–lx + 698 (London British Empire Cancer Campaign, 1963)

Thirty-seven of these tumours have been grown, twelve of them for periods of 4 days or more in the presence of various chemotherapeutic agents, including melphalan, chlorambucil, thioTEPA, methotrexate and mannitol myleran. Methotrexate proved wholly inactive in this system, possibly on account of the composition of the medium. The results of these studies were assessed by two parameters: the LD50, or dose of a drug (*in vitro*) found to kill 50 per cent of the cells present on the first day of the test, and the Tissue Culture Therapeutic Index which is the ratio between the LD50 of the drug *in vitro* and the dose required clinically to suppress the neutrophil leucocyte count by 95 per cent.

"The pattern of results obtained in the brain tumours was fairly consistent irrespective of histological type. Initially, i.e. in the first 48 hours, melphalan appeared to be the most toxic drug as expressed by the LD50 but was surpassed in most cases after 4 days by thioTEPA. The Tissue Culture Therapeutic Index, however, always favoured mannitol myleran on account of the non-toxicity of the latter drug *in vivo*."

Easty and Yarnell write: "The concept of rapidly growing tumour cells as being 'nitrogen traps' has led to the suggestion that plasma and other proteins may be ingested intact by tumour cells. The uptake of macromolecules is also of fundamental importance in the process of cell transformation using preparations of DNA or RNA. With this in mind the uptake of proteins from the medium by monolayer cultures of normal and malignant cells has been continued this year. The process has been followed using fluorescent-labelled proteins added directly to the medium, and by immunofluorescent staining with the fluorescent antibody technique. The proteins enter the cells by the process of pinocytosis, initially in the form of spherical vacuoles, which from an electron microscope study of Dr. E. H. Mercer are seen to be enclosed by a membrane originating from the plasma membrane.

"Cultures of twenty-seven different cell types, fifteen of 'normal' origin and twelve of 'tumour' origin, have been examined. The results have confirmed our earlier conclusions. Fibrocytes pinocytose vigorously, and sarcoma cells, presumably derived from connective tissue cells, behave similarly. Normal epithelial cells in primary culture pinocytose vary slightly, if at all, whereas epithelial cells which have been maintained in culture for many generations exhibit moderate pinocytosis, as do some carcinoma cells. Several of the lines of 'normal' epithelial cells are suspected of having undergone transformations, 'malignant' or otherwise. It is, therefore, not surprising that they should show properties similar to those of the carcinoma cells."

Ambrose *et al.* have examined carcinogenesis *in vitro*, that is, the action of the polyoma virus acting on tissue cultures of normal hamster kidney fibroblasts. "Further investigations indicated that this change from normal to tumour cell surface was dependent on an alteration in a sialic acid containing macromolecule (possibly mucoprotein or glycolipid). More experiments have now shown that the heterogeneity of the transformed cells after prolonged culture is due to some inherent instability of the transformed cells. When examined soon after the transforming event, the malignant cells consist of a homogeneous population having an electrophoretic mobility about 25 per cent greater than that of the normal clone. Experiments are in hand to elucidate further the nature of this enhanced surface charge, since this increase appears to be remarkably characteristic of the malignant change, whether carcinogenesis is by viral, hormonal or chemical agents."

At the Strangeways Laboratory in Cambridge, further experimental evidence has been obtained of the transforming effect of simply culturing cells *in vitro* without the addition of any specific carcinogenic agent. "It is a common experience in tissue culture laboratories that after prolonged cultivation cell lines usually become malignant, i.e. when injected into animals they form transplantable tumours.

"During the present investigation of the action of cobalt chloride on cells *in vitro*, two lines of dermal fibroblasts have been developed from the same pooled sample of dorsal skin from fœtal rats. Of the two lines, one (16*C*) has received no cobalt treatment, whereas the other (16*R*) was exposed intermittently to cobalt chloride during the first 8 months *in vitro* and became more tolerant of cobalt than the control (16*C*). The metabolic differences between the two lines after 6 months in culture have been described in a previous report (B.E.C.C. Report, 1959); they included a relatively low respiration and increased glycolytic activity in the cobalt-treated line which also, unlike the untreated line 16*C*, produced much hyaluronic acid. At that time, neither line formed tumours when implanted into rats.

"From the eighth month *in vitro*, the respiration of the control line 16*C* also began to fall, and by the eighteenth month it was similar to that of line 16*R*.

"The cells have now been grown *in vitro* for 3 years, and the effect of the injection of the two altered cell lines into rats has recently been re-investigated. For each line, approximately 10^7 cells were injected intramuscularly into the right thigh of each of ten rats. Both lines gave rise to tumours.

"The tumours produced by both the 16*C* and 16*R* cell lines were poorly differentiated fibrosarcomata with little intercellular material; both lines of tumours were invasive and transplantable."

The antigenic properties of these cells in culture have been investigated also at Cambridge. "An investigation is being made of the antigens of the two lines of rat fibroblasts, 16*C* and 16*R*, which, as mentioned above, have developed the ability to produce tumours when implanted into rats. Preliminary studies on the *B* antigen have shown that both lines consist of a mixed population of cells, some of which possess this antigen. Preliminary chromosomal analyses have revealed the presence, in many cells of each line, of one or more long metacentric chromosomes which are absent from normal rat cells. In both lines there is a wide range of chromosome complement, from less than the diploid to above the tetraploid number."

The discovery of cancer-producing viruses might have suggested that, even if no immunity could be created against the tumour, at least it might be brought about against so different an organism as a virus; moreover, the virus theory of the origin of cancer has been steadily gaining reinforcements since more and more viruses as carcinogenic agents have been discovered, for example, the mammary tumour virus, the leukæmic viruses of Gross, Friend, Graffi and Moloney, the polyoma virus of Stewart and some viruses in cattle.

Salaman finds that centrifugates and cell-free filtrates of thymus and lymph nodes from bovine malignant lymphoma when injected into mice increase the incidence of leukæmia from 0·5 to 9 per cent. He has also been working with the Moloney virus, which induces leukæmia in mice and is conveyed by vertical transmission (*VT*), that is, leukæmia develops in high incidence in the untreated progeny of virus-inoculated animals; *VT* has been reported for four murine leukæmogenic viruses (those of Gross, Graffi, Moloney and Friend). "Transference of virus during lactation was demonstrated by fostering experiments. Females in advanced pregnancy were placed in the upper half of a cage separated from the lower half by ½-in. wire mesh, and a foster-mother with a newborn litter (marked) in the lower half. The litter of the female in the upper half fell through the mesh within minutes of birth. Of thirty-one mice born of MLV-inoculated females and fostered by normal females, observed for 60 weeks, only one became leukæmic, at 49 weeks. Of nineteen mice born of normal females and fostered by MLV-inoculated females, five became leukæmic before the 15th week, and a further thirteen before the 50th week

"These results showed that MLV is transferred from mother to offspring during the lactation period, and no evidence was obtained of transmission from the father, or from the mother during the prenatal period They agree fairly closely with those of Law and Moloney, who used the same virus, though these authors also quote results, which they regard as equivocal, which appear to show that MLV may occasionally cross the placental barrier Gross (1961) found that his passage *A* virus passes from the mother, but not from the father, to the progeny "

The Moloney virus (MLV) will induce leukæmia in rats as well as in mice and is also conveyed by vertical transmission, of ten offspring of MLV-inoculated female rats mated to normal males, nine became leukæmic A further virus has been identified, the plasma lactic dehydrogenase-elevating virus of Riley (RV) which has been found in many standard transplantable mouse tumours with long laboratory histories and contaminates many strains of murine oncogenic viruses RV fails to induce neutralizing antibodies and it has never been shown to be leukæmogenic or oncogenic, the virus is transmitted to the offspring of females (which acquire the infection either naturally or by inoculation) during pregnancy, transmission occurs *in utero* and not via the milk

Workers at the Glasgow Veterinary School find that lymphosarcoma in domestic animals (cattle, the dog, cat and pig) cannot be transmitted to rats and mice, when examined in the electron microscope the tumour shows virus-like particles very similar to those found in mouse leukæmias Bovine papilloma is the commonest transmissible tumour of cattle, and electron micrographs of the virus show a close resemblance to the viruses of rabbit papilloma and to polyoma

Oettlé at the South African Institute for Medical Research reports that *Mastomys*, the Natal rat, which he discovered was very susceptible to spontaneous gastric cancer is now showing a high incidence of skin papillomatosis which occasionally develops into metastasizing carcinoma, Oettlé describes the condition as infectious papillomatosis

Sir Charles Dodds *et al* have been assaying the œstrogen content of poultry which has been treated with hexœstrol in order to improve weight and tenderness of the meat, but "has been regarded as a possible carcinogenic risk to the consumer In our experiments the œstrogenic residues were determined in the livers and flesh of three birds treated with a 25 mg pellet of hexœstrol implanted in the neck for six weeks before slaughter At the same time the tissues of three untreated birds were extracted in the same manner The tissues were completely extracted with ether, and the total phenolic fraction of this extract, which was considered to contain all the œstrogenic matter, was dissolved in arachis oil and assayed for œstrogenic activity by injection into groups of immature female mice

"The carcases of the hexoestrol-treated chickens contained a total œstrogenic activity corresponding to 1 96 μg of hexoestrol and the untreated chickens contained less than 0 04 μg In both cases the livers contained œstrogenic activity corresponding to approximately 0 9 μg hexoestrol" Clearly by the time the birds are eaten the injected œstrogen has been all but eliminated, that is, from 25 mg to less than 2 μg

Orr at Birmingham, working on the chemical induction of breast tumours in mice, finds that the C_{57} strain has a low incidence of spontaneous pseudo-pregnancy and is relatively insusceptible to breast carcinogenesis by methylcholanthrene, but virgin mice of the 1*F* strain and F_1 hybrid have a high incidence of spontaneous pseudopregnancy and are very susceptible to breast tumour induction "Pseudopregnancy attained by mating with vasectomised males causes the greatest increase in susceptibility in all three genetic types of mice, the effect being most noticeable in C57B1.

"In another experiment, F_1 hybrid virgins have had their own ovaries removed and replaced by ovaries from one of the parent strains or from similar hybrids This enables the response of different genetic types of F_1 hybrid breast tissue to tumour induction by MC while under the hormonal influence from ovaries to be investigated

"The results of these experiments may enable us to determine whether the genes controlling the susceptibility of the breast tissue to tumour induction by MC are acting indirectly through their effect on ovarian hormone production, or directly on the breast tissue itself "

Galton *et al* have been working on the Philadelphia chromosome discovered in the leukæmic cells of human subjects "Ten patients with chronic granulocytic leukæmia, untreated, treated and at varying stages of the disease, have all shown the Ph_1 chromosome in every cell in the bone marrow on direct preparation The frequency and significance of the presence of the Ph_1 chromosome and its relation to treatment in these ten patients over a period of 18 months forms the basis of material to be published shortly

"Two children, aged 11½ and 12, with chronic granulocytic leukæmia, both treated with busulphan for 4 and 8 weeks respectively, showed the Ph_1 chromosome in every cell in the bone marrow on direct preparation

"Chromosome studies in direct bone marrow and peripheral blood culture preparations obtained from patients with chronic lymphatic leukæmia are in progress in the hope of detecting differences between those patients with advanced but only very slowly progressive disease and those with more rapidly progressive disease "

As in previous years a very substantial proportion of research work sponsored by the British Empire Cancer Campaign is concerned with radiation research, and important findings are reported at all the different steps which intervene between the exposure to the radiation and the final biological injury

The new technique of flash radiolysis for detecting short-lived chemical species in water irradiated with μsec pulses of intense electron beams has been exploited highly successfully at two centres J P Keene (Christie Hospital, Manchester) first observed a broad band of optical absorption when pure de-aerated water was irradiated, and this proved the presence of a short-lived and highly reactive (particularly with oxygen) species other than OH and H radicals Parallel research at Mount Vernon Hospital, London (J. W Boag *et al*), appears to have established that this entity is a hydrated electron, and the chemical reactivity of this interesting intermediary is now being studied Whether hydrated electrons play a part in initiating biological damage remains to be discovered New techniques (Guy's Hospital Medical School, London) promise to provide direct evidence on the magnitude of the local heating effect along the track of an ionizing particle Rises in temperature of up to 100° C are calculated and it is conceivable that these may bring about the denaturation of protein molecules following irradiation in the solid state It has long been a puzzle why a single ionization anywhere within a protein molecule should result in far-reaching changes in its secondary structure

Following on the various physical processes, a variety of molecules in the irradiated material undergo irreversible chemical changes and some of these reactions constitute the primary lesions for radiation-induced cell death So far there is no clear evidence concerning the nature of the actual cell constituents involved There appears to be no increased radiation damage to DNA in cells rendered more radiosensitive by a variety of procedures (Chester Beatty Research Institute, London), and J Weiss also concludes from chemical investigation that DNA in nucleoprotein is highly protected against radical attack.

If not DNA, what are the sites of the primary lesions? A clue may be derived from the finding by L. H. Gray *et al.* that the permeability of cells is increased by a radiosensitizing treatment. It is also interesting that D. L. Dewey finds it necessary to explain his survival curves with bacteria by postulating the formation of a radiotoxin which is responsible for some of the lethal action of X-rays.

Many studies of factors which alter the radiosensitivity of cells are reported. They are of the greatest importance for mammalian radiobiology and in addition may throw light on the fundamental problems discussed above. Electron spin resonance techniques have made it possible to establish that the mechanism by which sulphydryl compounds protect the relatively simple system of salmon sperm heads against γ-rays involves repair of a radical by the hydrogen atom from the sulphydryl group (P. Alexander, A. Baker and M. G. Ormerod). This restitution reaction is prevented if the radical becomes peroxidized and the net extent of damage involves a competition between the sulphydryl compound and oxygen for the radical. Attempts have been made to correlate the radioresistance of different cell lines with their sulphydryl content. Changes in the physiological state of the cell have long been known to influence radiosensitivity to a marked extent. J. V. Davies and C. Russell now find that the magnitude of the sensitization obtainable by pre-irradiation treatment with nitric oxide depends on the metabolic character, while at Mount Vernon Hospital ageing of ascites cells *in vitro* increased the extent of chromosome damage, which was also enhanced if the cells were pretreated with ATP. The stage in the division cycle at which a cell is irradiated has been known to alter the dose required for killing the cell, and A. J. Bateman has now demonstrated for the mouse that the mutagenicity of X-rays varies in the different stages of spermatogenesis.

Radiosensitization by pyrimidine analogues and by sulphydryl poisons, such as iodoacetamide, of bacteria and mammalian cells *in vitro* has been investigated, but the mechanisms remain obscure. Although these treatments have to be given before irradiation the possibility that sensitization involves post-irradiation recovery processes cannot be excluded (Chester Beatty Research Institute, London). The same group finds that the composition of the growth medium and post-irradiation storage conditions critically alter the lethal effect of X-rays to leukæmia cells. The discovery made fifteen years ago at Oak Ridge that the survival of irradiated bacteria could be increased by storage for a few hours at sub-optimal growth temperature has now been extended to mammalian cells. This observation might be usefully linked to the ingenious suggestion of D. B. Cater *et al.* to heat up selectively by radiowave diathermy badly vascularized tumours. Blood-vessels act as cooling pipes and the cells most distant from blood-vessels will attain the highest temperature. J. Read in New Zealand has shown that yet another post-treatment—namely, exposure to infra-red—which was known to increase the effect of X-rays in plants also increases the lethal action of X-rays for mammalian cells *in vitro*. The dose of radiation needed to kill mammalian cells is clearly capable of being varied in many ways by both pre- and post-irradiation treatments, and it seems quite possible that further work along these lines may well be capable of practical application to radiotherapy.

On moving from the cellular level to irradiation of mammals many complexities are revealed. The treatment of radiation injury by bone-marrow transplants continues to be investigated at many laboratories, and there remain many intricate problems. E. A. Wright *et al.*, by combining protection by cysteamine and hypoxia with treatment with antibiotics and syngeneic bone-marrow, were able to increase the LD_{50} for mice to 8-MeV electrons from 940 to 3,520 rads. Data continue to accumulate concerning the importance of effects at a distance (or abscopal effects), and D. Maor and P. Alexander report marked biochemical alterations in lymphatic organs of rats following irradiation of the head only.

The ætiology of many of the delayed effects of radiation remains quite obscure. S. M. Landers and P. L. T. Ilbery (Sydney) find chromosome abnormalities in the thymus of irradiated mice long before these became leukæmic, and conclude that cells with altered karyotype were present before supervention of malignancy as judged by the criterion of transplantability. At Mount Vernon Hospital, an earlier observation that croton oil promotes skin tumour induction by β-rays has been confirmed.

The life-span shortening effect of whole-body radiation continues to be investigated. D. I. Connell compared the pathologies of irradiated and control animals killed at monthly intervals, and concludes that radiation cannot be considered as a generalized acceleration of normal ageing because the time course of different diseases is affected quite differently by irradiation. At St. Bartholomew's Hospital, London, very extensive investigations have shown a quite different disease pattern for mice sublethally irradiated at 4 weeks and at 30 weeks of age, and the researchers conclude that the cause of life-span shortening depends on the hormonal status of the mice at the time of irradiation. The same group has been quite unable to confirm in a very large-scale experiment an earlier American claim that a single dose of irradiation to male mice reduces longevity of their offspring. 350 r to the fathers even when repeated over three successive generations did not alter the life-span, disease incidence, fertility or growth rate of their progeny.

Amoroso and Stein-Werblowsky report some interesting observations on the association of the liability to cancer and pregnancy in rats. Using the so-called transplantable malignant chorion-epithelioma of Stein-Werblowsky, they found inhibition of tumour growth in the uterine horns of rats which contained post-coital secretion, compared with virgin rats, the tumour inhibition being maximal in fluid which had accumulated several hours post-coitally. In a second experiment tumours which were temporarily placed in the uterine horns of both virgin rats and in post-coital fluid failed to grow on transfer to a second host, and a similar result was obtained when tumours were exposed to post-coital fluid *in vitro*. Post-coital fluid is, of course, a composite, and it was found that by exclusion of spermatozoa (mating with vasectomized males) the resultant fluid had no anti-tumour activity, neither had the fluid in such matings after it had been incubated *in vitro* with spermatozoa. From this result they concluded that the uterus in presence of spermatozoa produces a tumour-inhibiting agent, or that spermatozoa in that environment release the active agent.

There are three reports on lymphangiography and its results; the art of outlining lymphatics is almost as old as the discovery of the lymphatic system, which is a system of blindly ending capillaries present in most parts of the body, the collected lymph being filtered at intermediate lymph nodes *en route* for the innominate veins into which the main lymphatic vessels ultimately empty. It is essentially an absorbative system. Most carcinomas, all the malignant lymphomas and some sarcomas involve the lymphatic system, and the very foundation of contemporary management of such cancers is to remove or otherwise destroy the regional lymphatic drainage of a malignant tumour, in addition to the treatment of a primary lesion. That the various methods attempted have met with some success there can be no doubt, but there are unsatisfactory aspects of the different procedures which need judgment in their use. For example, it is manifestly impossible to remove all the existent nodal lymphatic tissues in the axilla, yet radical mastectomy for carcinoma of the breast aims to do just this, as part of the operation. Removal of the rectal lymphatics can only be performed by removing the rectum and lower colon, with the consequent formation of an artificial anus, a standardized procedure for operable carcinoma of the rectum Irradiation of lymph nodes where for various reasons operation seems to be technically impossible, or fraught with risks to spread, is necessarily a blunderbuss affair, as all tissues in the fields of irradiation, sound or diseased, are severely injured The effectiveness cannot be guaranteed because the tumour cells may prove refractory, and, unlike the surgical procedure where the operation specimen can be examined histologically, it may never be known whether the procedure was deserved or not As may be guessed, the whole business of the management of the lymphatics in cancer is a fertile ground for argument between protagonists of the various procedures, for the good reason that in many fields the value of the different approaches is not conclusively proved

Lymphangiography is performed by injecting a radio-opaque oil into the lymphatics of an extremity and following its progress radiologically through the regional lymphatics and ultimately to remote lymphatics It is possible to distinguish involved nodes from uninvolved nodes where these are inaccessible to palpation (in the latter half of the twentieth century nothing has rivalled manual examination for assessing the state of palpable lymph nodes) The procedure may be unhelpful or even misleading, though, as with axillary lymph nodes, where many of them may be 1 mm in diameter and when eyth do contain a few malignant cells, as is not uncommonly found histologically, this is a situation clearly beyond the resolving power of contemporary radiological equipment On the other hand, it is possible that lymph nodes which are of any size can be accurately outlined and radio-therapeutic fields planned accordingly This seems to be a very worth-while technique, and over the next few years it is to be expected that the results will be forthcoming and its position in medicine and value in the management of malignant disease will be assessed

Malignant disease along with accident are the common causes of death in childhood, and a report from the Children's Tumour Registry at the University of Manchester is an analysis of a group of tumours called neuroblastoma comprising 54 cases, and another group of 14 cases with similar histology but not so designated on the grounds that they appeared to be primary in bone and that their clinical and biochemical behaviour was unlike secondary deposits of neuroblastoma in bone

Neuroblastoma is a tumour arising in the sympathetic nervous system, a fact often demonstrated anatomically or suggested by the histological appearances The special group of 14 cases the authors consider resemble a group delineated by the late James Ewing, after whom it is known eponymously as Ewing's tumour Histologically this group resembles the least differentiated but acceptable neuroblastomas The tables presented show an age of onset later than the first two years of life and show a worse prognosis than in the neuroblastoma group taken as a whole From their figures it is also apparent that the outlook for the group of neuroblastomas which occupy the same age groups as the Ewing's tumour is equally hopeless, but expectation of life in months is somewhat better. The debate on whether Ewing's tumour is an entity has been alive for more than two decades, and it appears that the present work has arrived at an impasse From the data presented it could be argued that Ewing's tumour and poorly differentiated neuroblastoma are variants of a common disease The problem involved does leave one to speculate on some of the limitations of the histological method and its place in the management of malignant disease The difficulty of assessment of the results of treatment and comparison between various methods in the first instance is having the same commodity to compare There is nothing in human tumours so far as standards of identity are concerned remotely comparable with the purity attainable by the chemist, and histological diagnosis is the most universally acceptable diagnostic criterion, since the material in which the diagnosis made is permanent and can always be reviewed

Since a histological opinion is ultimately a matter of subjective impression, clearly there must be some common ground or Babel would result and no useful communication between pathologists would be possible What is usually the situation is something like this—in the case of the rare, well-defined tumour there is universal agreement in diagnosis With regard to common malignant tumours, histological diagnosis would depend on how much of the specimen has been examined, for it is a frequent experience that the more tissue submitted to histological examination the wider the range of patterns will extend Patterns to the histologist are a reflexion of differentiation on the part of the tissue, progressive loss of the capacity to form the normal micro-anatomical appearances connoting anaplasia Ultimately with extreme anaplasia all tumours whatever their origins must look alike, and are only modified by local factors such as the presence, density and nature of any supporting stroma, the rates of cell division and death, and the local blood supply In this sort of situation the histologist only reporting on what he sees cannot really point to the anatomical site of origin of an undifferentiated tumour He could indicate perhaps certain lines of investigation which might lead to it, but by and large the problem of the undifferentiated tumour is a clinical and anatomical one Clearly, if an undifferentiated tumour arises in bronchus, cervix or bladder as it is likely to do, then it is respectively a carcinoma of the bronchus, cervix or bladder, irrespective of the fact that the three tissues are quite indistinguishable from each other histologically

The problem over Ewing's tumour is that the histological method has probably been pushed beyond its limits and that poorly differentiated neuroblastoma cannot really be differentiated from other similar anaplastic tumours The justification for splitting it off from the main group of diseases rests entirely on anatomical and clinical grounds It is reasonable to call the histological appearances undifferentiated tumour, thus leaving the question of its histogenesis open, but allowing the clinician to decide on its nosological status.

MEDIEVAL PREPARATIONS OF URINARY STEROID HORMONES

By Dr LU GWEI-DJEN and Dr JOSEPH NEEDHAM, F.R.S.
Gonville and Caius College, Cambridge

KNOWLEDGE of the physiology and biochemistry of the steroid sex hormones, both androgens and œstrogens, is a characteristic achievement of modern science stemming from nineteenth-century transplantation experiments and twentieth-century examination of the unsaponifiable lipins It would scarcely be expected, therefore, that in any phase of ancient or medieval science it should have been possible to make preparations which possessed activity of this kind

Recently, however, we have come across a corpus of material which indicates that just this was accomplished by the Chinese iatro-chemists between the tenth and the sixteenth centuries A.D. Guided by theories of traditional Chinese type, not of course the same as those of modern science, and using urine in large quantities (up to 300 gallons) as their starting-point, they succeeded in preparing mixtures of androgens and œstrogens in relatively purified form, and utilizing them in medicine for many hypogonadic conditions. The classical discovery of Aschheim and Zondek in 1927 that pregnancy urine contains large quantities of certain steroid sex hormones[1], and the subsequent recovery of these and others from other urinary sources, was thus strangely anticipated.

All the methods (we have translated six of them) start with large amounts of urine (as if on a modern pharmaceutical manufacturing scale), from adults or adolescents of each sex. The simplest, possibly the oldest, took the whole mass obtained by evaporating to dryness, including the steroid glucuronides and sulphates with much else, but most of the methods embodied various precipitations to obtain a colourless and odourless product. One used calcium sulphate, which would have assisted protein precipitation and therefore that of the conjugates also. Another made use of the saponins from the soap-bean tree, *Gleditschia sinensis*[2], the bean juice being added to the urine at the rate of one bowlful for every tub. The precipitate was afterwards extracted with boiling water, so that some steroids carried down on the protein were probably released as it denatured, while those combined with the saponins remained insoluble. Without *ad hoc* experiments, which it would indeed be interesting to carry out, one cannot say which steroid hormones could have been thus separated; but the quasi-empirical anticipation of the classical discovery of the digitonin precipitation of cholesterol by Windaus in 1909 is extraordinary[3]. Besides the vegetable protein added in the soap-bean juice, it is highly probable that other proteins were usually present, since in medieval times proteinuria would be expected among some of the numerous donors, and this would aid the precipitation of the steroid conjugates.

In nearly all the methods the process ends by a sublimation. At first this seemed difficult to understand, but in fact the urinary steroid sex-hormones do sublime unchanged in air between about 140° C and 280° C, there being considerable differences in sublimation temperature between them[4]. The description of the sublimation vessels in the texts is quite clear and unmistakable. Small earthenware pots were used with carefully luted covers, and great attention was paid to the degree and duration of heating. Chinese alchemists had been perfecting sublimation and distillation techniques since the second century B.C.; the iatro-chemists could therefore now prepare a rather purified mixture, as is indicated by the descriptions of the material as white, crystalline, glittering and lustrous or pearly like translucent jade. Finally, the sublimate was often emulsified with milk fat. Of course the end-products were complex mixtures of many different compounds, depending on the fractionation procedures used and on the original source material, but their pharmaceutical efficacy is vouched for by the descriptions of the conditions for which they were prescribed.

The six methods mentioned date from the eleventh to the sixteenth centuries A.D., and are preserved in Chapter 52 of the great Pharmacopœia of 1596 (*Pên Tshao Kang Mu*) by Li Shih-Chen from books no longer extant, or extremely rare. The oldest is the *Ching Yen Fang* (Tried and Tested Prescriptions) by Chang Shêng-Tao, dating from 1025, and quoted already in the *Chêng Lei Pên Tshao* of 1249. Then from the early years of the twelfth century A.D. we have two further descriptions in the *Shui Yun Lu* (Water and Clouds Record), written by a famous scholar, Yeh Mêng-Tê (1077–1148). Another book of the same period, the *So Sui Lu*, by an unknown author, theorizes about these preparations. The rest are in three books of the Ming period. If one asks how these medieval iatro-chemists could have been led to their urinary preparations, the answer surely is that classical Chinese medical and physiological theory envisaged a constant interaction among the organs of the body mediated through the circulating blood. Since the urine was considered as "of the same category as" (*thung lei*) the blood, then the virtues emanating from the organs might perhaps be found in it also.

The full material will appear in *Medical History*. For helpful discussions in its evaluation we thank Dr. Roger Short, Prof. H. Breuer and Dr. Hal Dixon.

OBITUARY

Dr. William C. Hayes

DR. WILLIAM CHRISTOPHER HAYES, curator since 1952 of the Egyptian Department of the U.S. Metropolitan Museum of Art, who died suddenly on July 10, was one of the outstanding Egyptologists of his generation, being equally celebrated as a historian, philologist and archæologist.

He was born at Hempstead, Long Island, on March 21, 1903, of an English father and of a mother who came of a prominent Philadelphia family. He was educated at St. George's School, Newport, where he won a medal for classics and graduated in 1924 at Princeton University. Here, two years later, he took his master's degree, having won a Carnegie scholarship for the study of medieval and Byzantine art, an interest which is reflected in his early paper on an engraved glass bowl in the Vatican Library. On being appointed to the staff of the Metropolitan Museum Egyptian Expedition in 1928, however, he henceforth devoted his talents to the study and elucidation of Ancient Egypt.

Hayes came comparatively late to his subject, and the only formal training in Ancient Egyptian that he received was with Sir Alan Gardiner at Oxford, where on occasions he stayed on his way home after the season's excavations. Nevertheless, he produced in 1935 his *Royal Sarcophagi of the XVIIIth Dynasty*, a remarkable and unique work in which his early discipline as an art-historian as well as his Egyptological learning was brought to bear on the study of a whole group of monuments, and succeeded among other things in solving some long-standing problems concerning the history of the Dynasty. This model publication, for which he received a Ph.D. from Princeton, was the first of a number of books and articles all characterized by the impact of a well-balanced and clear-sighted judgment and written by a master of English prose. His publication of a hieratic papyrus in the Brooklyn Museum, which he assembled from many hundreds of fragments, showed how an unpromising text could be transformed in his hands into a wealth of information on late Middle Kingdom social life and administration. His most recent works were four fascicles of the revised *Cambridge Ancient History*.

In Egypt he had largely been concerned with the reconstruction of the smashed statues of Queen Hatshepsut found by the Americans scattered in a quarry near her great temple at Deir el-Bahri and over a number of European museums He also, with Lansing, excavated the tomb of the parents of Sennemut, but when the Expedition closed its operations in Egypt in 1936, he returned to New York as an assistant curator in the Metropolitan Museum He had spent much of his spare time messing about in boats off the New England coast, and when the U S called up reserves in 1941 he joined the Navy, rising to the rank of lieutenant-commander and being decorated for gallantry in the Pacific theatre of the War He returned to the Museum in 1945 as associate curator. In 1959 he was appointed American representative on the International Committee for the Preservation of the Nubian Monuments He has left a widow and two sons.

A man of great integrity, quiet strength and a penetrating wit, Bill Hayes earned the respect and indeed the affection of all his colleagues on both sides of the Atlantic The loss to Egyptology by his unexpected death with much of his work still in draft form is a grievous one

C. Aldred

NEWS and VIEWS

The Royal Society: Officers for 1964

At the Anniversary Meeting held on November 30, Sir Howard Florey, provost of the Queen's College, Oxford, and formerly professor of pathology in the University of Oxford, was re-elected president of the Royal Society.

The other officers re-elected for the ensuing year were *Treasurer*, Lord Fleck, formerly chairman of Imperial Chemical Industries, Ltd , *Physical Secretary*, Sir William Hodge, Master of Pembroke College and Lowndean professor of astronomy and geometry in the University of Cambridge; *Foreign Secretary*, Sir Patrick Linstead, rector of the Imperial College of Science and Technology Prof A A Miles, director of the Lister Institute and professor of experimental pathology in the University of London, was elected biological secretary

The other members of Council elected (or re-elected, marked *) were Prof P M S Blackett, professor of physics in the Imperial College of Science and Technology, Prof A R Clapham, professor of botany in the University of Sheffield, Prof A H Cottrell, Goldsmiths' professor of metallurgy in the University of Cambridge, Prof C A. Coulson, Rouse Ball professor of mathematics in the University of Oxford, *Prof E F Gale, professor of chemical microbiology in the University of Cambridge, *Prof E L Hirst, Forbes professor of organic chemistry in the University of Edinburgh, Prof B Katz, professor of biophysics in University College (University of London), *Prof D Lewis, Quain professor of botany in University College (University of London), Sir Bernard Lovell, professor of radio astronomy in the University of Manchester and director of the Nuffield Radio Astronomy Laboratories, Jodrell Bank, *Dr P B Medawar, director of the National Institute for Medical Research, *Prof W T J. Morgan, deputy director of the Lister Institute and professor of biochemistry in the University of London, Prof A. B Pippard, John Humphrey Plummer professor of physics in the University of Cambridge, Prof J W S Pringle, Linacre professor of zoology in the University of Oxford; Sir Ewart Smith, formerly a deputy chairman of Imperial Chemical Industries, Ltd , Prof J H Taylor, professor of geology in King's College (University of London), *Dr H W Thompson, university reader in infra-red spectroscopy, Oxford

(Publication of the presidential address and award of medals at the anniversary meeting of the Royal Society has been deferred until the issue of December 28)

Chief of Electrical Instruments Section at the National Bureau of Standards: Mr F. L. Hermach

Mr F L Hermach has been appointed chief of the Electrical Instruments Section in the Electricity Division at the National Bureau of Standards, U S Department of Commerce Mr Hermach replaces Dr F M Defandorf, who died in August Born in Bridgeport, Connecticut, in 1917, Mr Hermach has been with the Bureau since 1939 He received a B E E in 1943 from George Washington University In 1954, he was the recipient of the Commerce Department's Silver Medal for Meritorious Service for his contribution to the standardization of electrical measurements in the development of a highly accurate transfer instrument for measurements In that same year, Mr Hermach received a Superior Performance Award from the National Bureau of Standards As chief of the Electrical Instruments Section, Mr Hermach will be concerned with the dissemination of values for a c and d c standards for use in measuring electric current, voltage, power, and energy from very low to very high values He will also be responsible for miscellaneous electrical measurements needed for engineering purposes.

Chemical Engineering at Monash University: Prof. O. E. Potter

Dr O E Potter, at present reader-in-charge of the Department of Chemical Engineering at the University of Melbourne, has been appointed to the foundation chair of chemical engineering at Monash University After graduating with honours in applied science from Queensland University, and completing a Master's degree, Dr Potter proceeded on a Queensland Foundation travelling scholarship to University College, London, where he read history and philosophy of science Later he became a lecturer in chemical engineering at the Manchester College of Science and Technology in the University of Manchester, where he also completed a Ph D on a number of fundamental aspects of liquid–liquid reactions In 1960, Dr Potter was appointed reader-in-charge of the Department of Chemical Engineering in the University of Melbourne and head of the Department in the Royal Melbourne Institute of Technology At that time the Institute had a very limited staff, while there was no permanent University staff Through Dr Potter's very considerable personal efforts, staff was obtained for both Departments, laboratories were vitalized and student numbers began to increase Postgraduate research was started, so that after only three years there are twelve full-time students for higher degrees Dr Potter has wide research interests in fluidization investigations, mass transfer phenomena and technical kinetics He has published a number of scientific papers in these fields and has contributed the section on technical kinetics in the *Chemical Engineering Practice* series

Physiology in the University of Malaya, Kuala Lumpur: Prof G. Barber-Riley

Dr. G Barber-Riley, lecturer in physiology in the University of Cape Town and formerly lecturer in physiology in the University of Liverpool, has been appointed the first professor of physiology in the University of Malaya, Kuala Lumpur Dr Barber-Riley was born in 1920 He was educated at Wallasey Grammar School. Between 1941 and 1946 he served with the R A F V R, holding the rank of warrant officer, with the duties of observer, and later navigator and wireless operator He made many sorties over Europe, including low-level flights in *Mosquitoes* After the War he first studied in the University of Manchester (1946–48) and then became a medical student in the University of Liverpool, graduating M B, Ch B in 1958 He had intercalated a year of study for the B.Sc honours degree in physiology, which he obtained in 1955. He was an assistant lecturer in the Department of Physiology of the University of Liverpool during 1958–60, when he obtained the degree of M D. He was then appointed to the post of lecturer in physiology in the University of Cape Town He has published a number of papers, alone or in collaboration with others, mainly on clinical and experimental aspects of liver function

University of Keele. Statistical Research Unit in Sociology

MR B DE VOS has been appointed the first director of the new Research Unit in Sociology of the University of Keele He will take up the appointment from January 1, 1964 Mr De Vos has been a director of the Gallup Poll for the past five years He will remain a director of that organization As director of the Unit, he will be responsible for developing new sociological studies based primarily on sample survey techniques and also for reinforcing the strong links already existing between the different departments and disciplines at Keele Since its foundation in 1949, one of Keele's special features has been the maintenance of close links between different disciplines and the avoidance of over-specialization within departments Up until now, there has not been a separate Department of Sociology, although considerable emphasis has been placed on the sociological aspects of studies in the Departments of Economics, Education, Geography and Politics The formation of the Research Unit has been made possible by a gift of £50,000 from the Nuffield Foundation The University is also responsible for running the *Sociological Review*

Transport Investigations at the Imperial College of Science and Technology

THE Nuffield Foundation has granted £45,500 to the Imperial College of Science and Technology to enable Prof C Buchanan to continue the investigations on which he has recently been engaged in the Ministry of Transport Mr David Crompton and Mrs Ann MacEwen, who worked with Prof Buchanan in the Ministry, have been appointed Research Fellows at the College The particular topics which it is proposed to study are American transportation survey methods, the use of cost-benefit analysis for urban roads and redevelopment projects, environmental standards in relation to traffic, and alternative movement systems for urban areas The appointment of Prof Buchanan to the newly established chair of transport tenable at the College was announced earlier in the year (*Nature*, **197**, 1153, 1963)

Transportation and Economic Growth

A BOOKLET being distributed by the Battelle Memorial Institute, entitled *Can New Transportation Concepts Contribute to Economic Growth ?*, directs attention to the lack of the integrated knowledge needed to answer some of the basic questions relating to the efficient and economic operation of transport facilities (Pp 8 Columbus, Ohio Battelle Memorial Institute, 1963) Solutions of such problems, it is argued, have frequently been designed to meet the immediate needs of specific and narrowly defined situations, and further research to gain knowledge of the interactions of various parts of the complex would contribute substantially to economic growth

International Bureau of Time Uniform Time and Constant Frequency for the Year 1964

FOLLOWING the decision of the International Committee of Time at its meeting in Berkeley during August 1961, and the General Assembly of the Union Radioscientifique Internationale at its meeting in London during September 1960, and the plenary assembly of the Comité Consultatif International des Radiocommunications at Geneva during January–February 1963, the International Bureau of Time consulted the observatories which have cæsium atomic resonators and compared their astronomical observations It has now calculated the nominal value of the frequency to transmit during the year 1964 as -150×10^{-10} with regard to the scale of time such that the frequency of cæsium has the value $f(\mathrm{Cs}) = 9\ 192\ 631\ 770$ c/s The value indicated will not change during the course of 1964 The International Committee of Time, the Union Radioscientifique Internationale and the Comité Consultatif International des Radiocommunications recommend that the value of the frequency indicated by the International Bureau of Time should be utilized by all organizations wishing to transmit uniform time and constant frequency.

Physical Review and *Physical Review Letters*

IN spite of the number of new periodicals that have been launched in recent years to deal with specialized branches of physics, editors still find it difficult to satisfy the demand for additional space for the publication of papers submitted to them *The Physical Review*, which has until now been issued at fortnightly intervals but which has been considerably expanded during the past few years, is to become a weekly as from January 1964 The fifty-two issues in the calendar year will each be dated on the Monday of the week of issue and will be divided into four volumes of thirteen issues each, with the thirteenth issue consisting of a comprehensive quarterly index The first twelve issues of a volume will be divided into two sections, *A* and *B*, of six issues each, appearing alternately Section *A* will be devoted to atoms, molecules and condensed matter, and Section *B* to the physics of nuclei and elementary particles The quarterly index will be a combined one relating to both Sections *A* and *B* Subscriptions must cover both sections The cost to members of the American Physical Society will be increased by five dollars In a parallel move, *Physical Review Letters* will also be issued weekly and will consist annually of two volumes of twenty issues each There will be no division of subject-matter and there will be no increase in size or subscription

Automata Theory and Information Retrieval

THE expressed purpose of the survey, *The Application of Automata Theory to Problems in Information Retrieval*, by R A Kirsch, is to suggest certain topics in automata theory that may be explored so as to achieve further understanding of the information retrieval problem (National Bureau of Standards NBS Report 7882 Pp ii+70 Washington, D C U S Department of Commerce National Bureau of Standards, 1963) The literature of automata theory is intimately connected with the study of machines, and in early literature the machines studied were intended to appear lifelike However, in the more recent literature the emphasis is on information processing, with many papers on the design of computor-life devices and switching circuits Papers dealing with the early approach and with the design of devices and switching circuits are excluded from the selected bibliography given at the end of the survey Attention is directed more to the abstract area of automata theory On the subject of finite automata, literature concerned with problems in representing languages, rather than with studies of relations between finite state languages and the memory requirements or structural constraints which they impose on the machines which generate or recognize them, are listed in the bibliography Certain references to recursive function theory are included. in addition to some on mechanical theorem proving, especially those which make use of syntactic techniques and a technique based on the expansion theorem of Herbrand The particular applications discussed in the survey are information retrieval systems for processing natural language, dealing first with automata theory as a source of mechanisms for the description of English text; and secondly, with automata theory for the description of other phenomena as languages, artificial languages in information retrieval systems, including a brief consideration of the algorithmic language ALGOL, inference in information retrieval systems, and theoretical feasibility and complexity questions The bibliography consists of 321 items

Research in Space Science

SELECTED papers from the Special Reports in Space Science issued by the Astrophysical Observatory of the Smithsonian Institution during the years 1958–61 are brought together in *Smithsonian Contributions to Astrophysics*, 6, *Research in Space Science* (Pp vii+242 Washington, D C Government Printing Office, 1963. 2 dollars) The Smithsonian Astrophysical Observatory has been among the leaders in several branches of space research—the optical tracking of satellites, the determination of orbits from observation, the use of these orbits for geophysical studies, the development of orbital theory, etc.—and the papers are, therefore, of considerable interest as a record of progress in these subjects Some of them are printed as they originally appeared (including one which was in error and is corrected 15 pages later); but others have been revised in varying degrees The authors include regular members of the Smithsonian Astrophysical Observatory, such as L G Jacchia and I G Izsak, and visiting consultants, such as M Nicolet and Sir Harold Jeffreys This publication is supplemented by *Smithsonian Contributions to Astrophysics*, 8, No 1, *Accurate Drag Determinations for Eight Artificial Satellites, Atmospheric Densities and Temperatures*, by L G Jacchia and J Slowey (Pp ii+99 Washington, D C Government Printing Office, 1963 65 cents) In this report the rate of decrease of orbital period for eight satellites during the years 1958–61 is evaluated from field-reduced observations with Baker–Nunn cameras, and the upper-atmosphere densities and temperatures are then determined The report is notable for its accuracy and wealth of detail, the variations in density and temperatures at heights of 300–700 km, both short-term and year-by-year, being fully displayed.

Chesapeake Bay Bridge–Tunnel

SOME facts about the nearly completed bridge and tunnel crossing from Wise Point, Va, to the Virginia shore 15 miles from downtown Norfolk are of interest to Britain and France in view of the controversy that has raged over the possibility of bridging the English Channel, as opposed to a tunnel link under the Straits of Dover This project overcomes the last and most formidable obstacle on the 998-mile Ocean Highway between New York and Florida It is acclaimed not only as one of the world's modern engineering wonders but also as " man's longest span across navigable ocean water" "The stream of seagoing traffic will inaugurate a spectacular 17 6-mile system of trestles, man-made islands and tunnels that draws the boundary between the Atlantic Ocean and Chesapeake Bay". More than two-thirds of this Highway is 30 ft above water, elevated on 2,600 concrete legs, each 54 in in diameter and embedded 100 ft into the sea-floor The structure is designed to withstand hurricane winds, a 10-ft rise in sea-level, and even 14 5-ft ocean swells The tunnel sections account for two miles of the total span, one being 5,450 ft long under the Chesapeake Channel, the other 5,738 ft under Thimble Shoal—both are main shipping channels Each tunnel, stated to be as wide and high as a three-storey building, was prefabricated, floated to site, then encased in concrete and sunk end-to-end in deep trenches excavated under the shipping lanes The vital statistics of this bridge–tunnel are that it took 1,000 men 3 5 years to construct, used 550,000 cubic yards of concrete, 55,000 tons of steel; 34,000 carloads of rock, and more than 5 million cubic yards of sand-fill Another interesting feature of the design is the use of 14,700 elastic bearing pads the size of "standard desk dictionaries" "Laminated of neoprene synthetic rubber around steel plates . . the pads separate elevated 75-foot, 65-ton road sections from their supports. Thus they prevent concrete grinding and cracking caused by movement from thermal expansion and contraction or wind and water current". An illustrated article entitled "Seagoing Roadway Rides on Rubber", by H E Davis, published in the *Du Pont Magazine* (57, No 4, 13, July–August, 1963) and from which the foregoing data are taken, gives many other technical details of this remarkable achievement

Antibodies

Antibodies is the title of a recent issue of the *British Medical Bulletin*, which contains a series of authoritative articles by recognized experts each dealing with a particular aspect of the study of these substances (19, No 3, September 1963. *Symposium on Antibodies* Pp 169–262+4 plates London The British Council, 1963 30*s*) Concise papers on the nature of antigen–antibody reaction, sensitivity of methods of detecting antibodies, the isolation of antibodies, their chemical structure, γ-globulin metabolism, factors affecting antibody response, origins of immunological competence, as well as the nature of antitoxins, reagins, and auto-antibodies are among topics included In the introduction, Prof A A Miles, the chairman of the planning committee of *Antibodies*, reminds us that the story of antibodies began in 1890 with the demonstration by von Behring and Kitasato of the specific antitoxic property of the serum of animals some weeks after the injection of tetanus toxin Almost three-quarters of a century has passed since then, and during that time not only has detailed knowledge of the subject increased enormously, but also we have a much deeper understanding of the process of antibody production. The editors are to be congratulated on having compressed so much into the space available and yet left us with a lucid and fascinating picture of present-day ideas on this important aspect of immunology

Archæology in Western New South Wales

A RECENT issue of the *Records of the Australian Museum* contains an important article on "The Archæology of Mootwingee, Western New South Wales", by F D McCarthy and N W G MacIntosh (Vol 25, No 13, December 3, 1962 Pp 249–298+plates 19–27 Sydney The Australian Museum, 1962) This describes the paintings and engravings which can be seen in two principal sites, called Main Gallery and Dingo Rock The existence of this art has been known for 100 years, and was probably discovered by a member of the Burke and Wills party in 1860 The art consists of representations of humans, weapons and animals, and is considered in some cases to show incidents in the life of the Aborigines. The Dingo Rock decorations are believed to be at least 300 years old, probably more, on the basis of the fracturing and weathering of the rock following its engraving. The report attempts to interpret some of the scenes and objects in the light of local information, while knowledge of the technique of the engravings has been lost, certain groups can to-day be explained as portrayals of Aboriginal myths In the same area, a series of painted rock shelters were recorded, and excavations made of certain of their floor deposits In no case can the stone implements recovered be related to the series of paintings, and it seems probable that occupation of these shelters ceased well before the decoration was made

Paul Instrument Fund Grants

THE Paul Instrument Fund Committee has made grants as follows £12,800 to A H W Beck, lecturer in engineering, University of Cambridge, for the construction of apparatus for the amplification and generation of extremely high frequency electromagnetic waves (below 1 mm), £2,630 to Dr B V Bowden, principal of the Manchester College of Science and Technology, for the continuation of work on the development of narrow pass band dye filters (for night sky astronomical photography), £1,000, as a supplementary grant, to Dr S Evans, senior assistant in polar research, University of Cambridge, for the development of an instrument for measuring the depth of continental ice sheets by a radar technique, £1,870 to Dr E T Hall, director of the research laboratory for archæology and the history of art, University of Oxford, for the development (*a*) of a fully transistorized differential flux-gate magnetometer, and (*b*) of a miniaturized flux-gate compass, £725, as a supplementary grant, to Dr D W Hill, senior lecturer in physics, Research Department of Anæsthetics, Royal College of Surgeons of England, for the construction of an infra-red gas or vapour analyser using interference filters, £5,250 to Dr J V P Long, assistant director of research in the Department of Mineralogy and Petrology, University of Cambridge, for the development of an ion-probe analyser for mass spectrometric measurements on selected micro-volumes of 1–20μ diameter in polished specimens of minerals and metals, £5,690 to Prof J Ring, Department of Applied Physics, University of Hull, for the construction of apparatus for research into the applications of Moiré fringes as analogue Fourier transformers, £2,300 to Dr T H Wilmshurst, Department of Electronics, University of Southampton, for the construction of an electron spin resonance spectrometer for examining short-lived paramagnetic species produced by a pulsed light source

The Paul Instrument Fund Committee, composed of representatives of the Royal Society, the Institute of Physics and the Physical Society and the Institution of Electrical Engineers, was set up in 1945 "to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much improved types of physical instruments and apparatus for investigations in pure or applied physical science"

The Indian Botanical Society: Awards

To commemorate the sixtieth birthday of Prof P Maheshwari, University of Delhi, the Indian Botanical Society presented him with an advance copy of the *Maheshwari Commemoration Volume* in recognition of his work of exceptional merit for the advancement of botanical research in India The *Volume* is a compilation of articles contributed by eminent botanists from all over the world and represents almost all disciplines of botany It is expected that it will be published in a month or so

The Society awarded the Birbal Sahni Medal for 1962 to Prof T S Sadasivan, Madras University, for organizing, promoting and fostering botanical studies in India Prof Sadasivan is the sixth recipient of this award

University News: London

The following titles have been conferred *Professor*, Dr J M Alexander (engineering plasticity), in respect of his post at the Imperial College of Science and Technology, Dr. T Barnard (micropalæontology), in respect of his post at University College, Dr F. R Bell (experimental veterinary medicine), in respect of his post at the Royal Veterinary College, Dr L P Mair (applied anthropology), in respect of her post at the London School of Economics, Dr M J Seaton (physics), in respect of his post at University College *Reader*, Dr D E Barton (statistics), in respect of his post at University College, Mr H. Billett (mechanical engineering), in respect of his post at University College, Dr W G Chaloner (botany), in respect of his post at University College, Dr R W Guillery (anatomy), in respect of his post at University College, Dr K J Ives (civil and municipal engineering), in respect of his post at University College, Dr V. H T James (chemical endocrinology), in respect of his post at St Mary's Hospital Medical School, Dr C R Boddington Joyce (psycho-pharmacology), in respect of his post at the London Hospital Medical College, Mr O C J Lippold (physiology), in respect of his post at University College, Dr D H Martin (physics), in respect of his post at Queen Mary College, Dr D V W. Parke (biochemistry), in respect of his post at St Mary's Hospital Medical School, Dr A F Seager (mineralogy), in respect of his post at Birkbeck College, Dr D A Walker (botany), in respect of his post at Queen Mary College The following appointments to readerships have been made: Dr E M. Deuchar (embryology), tenable at University College, Dr B R Rabin (biochemistry), tenable at University College, Dr C W. Rees (organic chemistry), tenable at King's College

Announcements

MISS RACHEL CARSON, author and ecologist, and Prof H Clifford Darby, professor of geography in University College, London, have been awarded the Cullum Geographical Medal and the Charles P Daly Medal, respectively, by the American Geographical Society for their respective contributions in the fields of conservation and geography. Miss Carson, who is well known for her books, *Silent Spring* and *The Sea Around Us*, has been affiliated with the Marine Biological Laboratory, Woods Hole, Mass, since 1929 Prof Darby is known most widely for his work in historical geography, particularly for his book, *The Domesday Geography of England*, of which four volumes have so far been published, earlier this year he was awarded the Patron's Medal of the Royal Geographical Society He was president of the British Institute of Geographers in 1961

AT the tenth general assembly of the International Council of Scientific Unions held recently in Vienna, Dr H W Thompson, of St John's College, Oxford, and university reader in infra-red spectroscopy, was elected president of the Council for the next two years Prof D Blaskovic, vice-chairman of the Czechoslovak Academy of Sciences and director of the Academy's Virological Institute, was elected secretary-general, and Ing Gen. G Laclavère, National Geographic Institute, France, was elected treasurer

THE *Memoirs and Proceedings*, 1962–63, of the Manchester Literary and Philosophical Society (105 Pp 128+xlix Manchester Manchester Literary and Philosophical Society, 1963 31*s* 6*d*) contain M W Thring's Joule Memorial Lecture, "Can Machines make Humans Happier ?", and papers by E Mendoza on the history of the kinetic theory of gases, by F C Toy on universities, research associations and industry, and by S Toulmin on the discovery of time The volume also includes the annual report of the Council, and lists of special lectures, members and members of Council

THE twelfth inter-university geological congress entitled "The Present is the Key to the Past" will be held in the University of Sheffield during December 15–18 Further information can be obtained from H G Davies, Department of Geology, University of Sheffield, Mappin Street, Sheffield, 1

A SYMPOSIUM on "The Use of Redundancy in System Design", arranged by the Systems Engineering Section of the Society of Instrument Technology, will be held at the Northampton College of Advanced Technology on February 14 Topics under discussion will include automatic landing of aircraft, nuclear power systems, techniques of redundancy in logical circuits, reversionary modes in complex systems Further information can be obtained from the Symposium Secretary, Society of Instrument Technology, 20 Peel Street, London, W 8

BRITISH AID TO DEVELOPING COUNTRIES

*Aid to Developing Countries** outlines developments in Britain's economic assistance to developing countries since the White Paper, *Assistance from the United Kingdom for Overseas Development*, was issued in March 1960 (see *Nature*, 186, 501; 1960), and describes briefly Britain's present-day effort. The total flow of resources from the industrialized nations of the Free World to the developing countries is at present running at about £3,000 million a year, one-third of which consists of private investment. Of the £2,000 million from public funds, more than a half comes from the United States; the British Government has provided £1,367 million since the end of the Second World War, and the present contribution is £148 million, compared with £151 million in 1960–61 and £160 million in 1961–62, the decrease being due to the inability of overseas Governments to take full advantage in that year of the funds placed at their disposal, particularly in the way of loans. British private investment, mostly in the more developed countries of the Commonwealth, is running at about £300 million a year, but is tending to level off or decline. The British Government is participating in an examination, in the Development Assistance Committee of the Organization for Economic Co-operation and Development, of the feasibility and desirability of multilateral investment assurance. Moreover, it is supporting the proposal of the International Bank for Reconstruction and Development to set up a centre for conciliation and arbitration on investment disputes as well as an attempt to draw up a convention for protecting foreign investors.

Of the present annual expenditure on overseas aid, about one-sixth is spent on technical assistance, and only part of this is a direct charge on Britain's balance of payments. Since December 1962 something like £15 million of additional aid has been offered from surplus productive capacity. Of bilateral aid totalling £138 million in 1962–63, £60·6 million was to Colonial territories and £62·3 million to independent Commonwealth countries, the proportion of grants to loans being 2 : 1 for the former and 1 : 2 for the latter. After summarizing in some detail the distribution of capital aid, the White Paper summarizes the effort in technical assistance, more particularly since the first progress report of the Department of Technical Co-operation was issued in April 1962, and the White Paper on overseas recruitment policy in May 1962. Expenditure on technical assistance is estimated at £30·3 million in 1963–64, or 25 per cent more than in 1961–62; about half this is for the Overseas Service Aid Scheme, in which 39 Governments now participate and some 15,400 officers are covered, 8,900 on permanent and pensionable terms. In 1962 the Department of Technical Co-operation made 1,042 appointments compared with 880 in 1961; another 187 appointments were made through the British Council, and 408 through the Crown Agents.

Voluntary service is of growing importance: 296 volunteers went out in 1962, 550 are going during 1963, and it is planned that 800 should go in 1964; school-leavers numbered 262 in 1962, 300 in 1963, and 300 are planned for 1964; for graduates these figures are 36, 250 and 500. Besides running the school-leavers scheme, Voluntary Service Overseas is sending more than half the volunteers under the graduate scheme. About £17 million is being spent directly from public funds as British aid in education and training, apart from contributions to international agencies assisting in this field. In 1961–62 659 fully qualified teachers left Britain for non-university posts in developing Commonwealth countries and 87 non-university teachers were recruited for developing foreign countries, while recruitment has since increased. On the advice of a Committee under Sir Charles Morris as chairman (see *Nature*, 198, 919; 1963), the Secretary for Technical Co-operation proposes during 1964 to make up to 25 special Commonwealth awards to eminent British academic persons willing to serve for two or more years in universities in developing Commonwealth countries, and the Inter-University Council continues to find candidates for more than 200 posts a year. The British Institute of Management has been given a grant of £5,000 for clearing-house activities in training for management, and schemes for East Africa and for Asia are being prepared.

Of more than 60,000 full-time overseas students at British universities, training colleges and other institutions, two-thirds are from the developing countries. These also represent a substantial contribution on Britain's part to the educational development of these countries, and some £3 million is expected to be spent in 1963–64 in this way by means of scholarships, fellowships and other awards for study in Britain. The British Council is also administering a Government grant of £3 million towards the cost of providing additional residential places for overseas students.

On research the White Paper gives little information. Part of the £2·15 million provided through the Department of Technical Co-operation in 1963–64 for research into the economic and social problems of developing countries is devoted to the support in Britain of research institutes dealing with tropical problems, such as the Tropical Products Institute, the Anti-Locust Research Centre and the Tropical Divisions of the Road Research Laboratory and the Building Research Centre. Significant financial support is given to the Tropical Metabolism Unit of the Medical Research Council in Jamaica, to the Tropical Fish Culture Research Institute in Malaya and to various Regional Research Centres in the tropics, while the specialist advisory staff of the Department of Technical Co-operation are constantly assisting overseas Governments in the investigation of particular problems. No real idea of the scale or extent of the contribution to research can, however, be gained from the White Paper, but there is some further reference to assistance in the medical field, in agriculture and in surveys.

In medicine, the Government has accepted most of the recommendations of the Working Party under the chairmanship of Sir Arthur Porritt on medical aid to developing countries (see *Nature*, 198, 719; 1963), including the creation of 25 postgraduate bursaries at British universities and the establishment of 12 senior and 6 junior lectureships at the London and Liverpool Schools of Hygiene and Tropical Medicine. In agriculture the Government has agreed to contribute £52,000 a year for three years towards the cost of the Graduate School of Tropical Agriculture in the University of the West Indies in Trinidad and will also provide up to 20 studentships a year for British agricultural graduates to take this course in preparation for overseas service. Grants are also being made to expand facilities at the Royal Dick Veterinary College in Edinburgh for training in tropical veterinary medicine and to the Commonwealth Forestry Institute at Oxford for a similar purpose. Through the Directorate of Overseas (Geodetic and Topographical) Surveys, the Department of Technical Co-operation is providing the basic topographical mapping for more than 30 countries, and since 1949 one million square miles have been mapped. The Directorate also undertakes the preparation of medium-scale maps required for individual development projects, and assistance is also provided in geology and related matters, including advice on the development of mineral resources and the recruitment and training of geologists for employment overseas.

---

* H.M. Treasury. *Aid to Developing Countries*. Pp. 51. (Cmnd. 2137.) (London: H.M.S.O., 1963.) 3s. net.

The White Paper concludes with a brief review of Britain's contribution to multilateral aid, including technical assistance, which is given mainly through the International Bank for Reconstruction and Development, the International Development Association and the International Finance Corporation. To the United Nations Expanded Programme of Technical Assistance and the Special Fund, Britain contributed in 1963 just more than £3·5 million, an increase of 25 per cent on 1962. In mid-1962 there were 431 British experts in the field under United Nations programmes—more than those of any other single nationality—and in 1962–63 we provided study facilities for 751 fellowships financed by the United Nations. Besides a current contribution of £350,000 to the United Nations International Children's Emergency Fund, which has now taken on functions in health, nutrition, education and family service, Britain contributes to the annual programme of aid to the developing members of the Organization for Economic Co-operation and Development, Britain's proportion of the 1963 allocation of £657,000 being 16·3 per cent, through the general budget of the Organization.

THE BRITISH BROADCASTING CORPORATION

THE annual report for 1962–63 of the British Broadcasting Corporation* is concerned largely with the plans for the Corporation's second television programme, which it is hoped to open in the London area in April 1964 with some 25 h of broadcasting a week. This should be extended to the Midlands about a year later and, by the end of 1966, about two-thirds of the population should be covered. Equipment has been ordered, plans for the siting of new transmitters have been discussed with the Post Office and with the Independent Television Authority, and recruitment for the new service has been commenced. The staff employed on March 31, 1963, numbered 17,930 full-time and 1,010 part-time, compared with 17,125 and 887, respectively, on March 31, 1962: the higher rate of recruitment and higher proportion of engineers to technical assistants noted last year is likely to continue during 1963–64. A number of the 170 engineers and 450 technical assistants and operators required for the new television programme have already been recruited.

Introduction of colour television is at present planned for 1965, and, in view of the desirability of the whole of Europe, if at all possible, working on the same system, the Corporation arranged a series of colour demonstrations in London in July 1963 to which delegations from the European broadcasting organizations, including the U.S.S.R. and Eastern Europe, were invited. It is hoped that as a result of these and other demonstrations the European Broadcasting Union will be able to forward an agreed recommendation to the International Consultative Radio Committee in time for a final decision on a European standard to be reached in February or March 1964. All the Corporation's very-high-frequency transmitters will be equipped to transmit colour. There have also been discussions with other European broadcasting organizations in stereophony, but, while further experiments have been made, any decision on a regular service of stereophony in the United Kingdom is likely to be some years distant.

The Corporation's Television has been reorganized to meet the needs of a two-channel situation by creating two new posts of Chief Controller, under the overall control of the Controller of Programmes. The Post Office has set up a joint working group with both the Corporation and the Independent Television Authority to consider engineering matters concerned with the problems of the move to ultra-high-frequencies, and the starting of a second programme on 625 lines. While the Corporation regrets the Government's postponement of a decision to introduce local sound broadcasting, for which there was strong support in local government and university circles, it welcomes the new opportunities opened up for educational programmes of all kinds. An Adult Education Liaison Committee has been set up and a television series of adult education programmes was approved to start in the autumn of 1963. The Corporation is prepared to run a special educational programme to supplement the more general programmes, if needed and if the necessary finance is forthcoming, but it is strongly opposed to the idea of a separate educational authority to run such a programme.

Concern as to the financing of these developments continues. The report points out that unless the Government meets the situation created by its retention for a further six months of part of the proceeds of the £4 licence, a £6 licence will become necessary by April 1, 1965. In the meantime, some of the plans for expansion for which Government approval was given in June 1962 must be deferred. Arrangements are being pressed ahead for providing separate television coverage for Wales, and the best means of filling gaps in the existing coverage in Scotland are being considered. Some disappointment is expressed at the failure to make full use of the extensive very-high-frequency sound coverage: sales of very-high-frequency sets are declining, and the radio industry's plans for dual-standard television sets do not include provision for very-high-frequency sound.

On overseas broadcasting, the report observes that the year saw the thirtieth anniversary of the Corporation's External Services, and while competition is increasing the reputation of the Corporation remains high. Since 1955, the number of radio sets in the world has risen from 237 million to about 400 million, and, as last year, the Corporation ranks fifth in output; the U.S.S.R., the Satellite countries, the Voice of America and China, have increased their lead and in the same order. Audience surveys have revealed that the Corporation's programmes have particular appeal to younger people: half the listeners in the U.S.S.R., where ages have been established, are under 30, and two-thirds of those in France are under 20. Apart from the research and development in connexion with stereophonic broadcasting, the introduction of the 625-line standard and ultra-high-frequency, a continuous programme of work is in progress in connexion with long-distance propagation, which bears on the problems arising when transmitters in different parts of Britain and in the neighbouring countries of Europe operate in the same or adjacent frequency channels.

* Annual Report and Accounts of the British Broadcasting Corporation 1962–63. Pp. 188+16 photographs. (Cmnd. 2160.) (London: H.M.S.O., 1963.) 11s. 6d. net.

Further information on future developments is given in No 17 of *The B B C Record* (February 1963), which emphasizes the value of the two television services Moreover, it outlines the first year's proposals for adult education in television, and in the Sixth Bishop Bell Memorial Lecture, "Future Prospects in Broadcasting", delivered by H Carleton Greene, the director-general of the Corporation, on April 30, and now published as a pamphlet, Mr Greene stresses the complementary functions of the Corporation and the importance of concerning itself with the whole of the national life, with mass interests and with minority interests He suggests that if broadcasting planners do their jobs properly they can create and stimulate cultural and educational demands as well as meet them He directs attention to the use of television programmes in teaching and to the introduction of experimental programmes for use in technical colleges and colleges of further education Furthermore, he urges that it would not be right to make an educational channel a charge on licence revenue it should receive a separate grant-in-aid, as do the External Services.

SOILS AND LAND USE IN NORTH WALES

A SURVEY of the soils of North Wales was started by the late Prof G. W Robinson and his colleagues, who published several reports and maps in the *Welsh Journal of Agriculture*. The work has been completed recently with a memoir, and accompanying maps, which covers an area of 240 sq miles, stretching from Pentraeth, in Eastern Anglesey, and Llandudno in the north to Waenfawr and Bettws-y-Coed in the south* The Conway valley and most of the high land of Snowdonia are included

The climate is maritime and its most important influence in soil development is the rainfall, which increases steeply from some 30 in on the coast to 120 in on the mountains in the south. The parent materials of the soils include acid and basic igneous rocks, schist and shale and their derived drifts, non-calcareous clay and limestone, peat and various mixed drifts from igneous and sedimentary rocks The soil mapping and classification follow the custom of the Soil Survey and profile description includes information on site, drainage, parent material, horizons, colour, texture and structure Soils of five major soil groups have been recognized, namely, brown earths, calcareous, gley, podzolized and organic soils, but there is also a considerable area of immature soils occurring on youthful sands and alluvium Each is described and sub-divided into sub-groups and soil series, and again grouped into lowland, marginal and mountain soil zones

The larger part of the memoir is naturally taken up with detailed descriptions of the soil series and with appendixes on particular profiles and analytical data, but there is a chapter on land use, compiled with the assistance of G Edwards, H E Roberts and W A Lindsay-Smith This opens with a historical review of the area from the time of the disappearance of the valley glaciers, with inferences to be drawn from studies on pollen grains and dating by radioactive carbon, on changes in climate, flora and human settlement Recent agricultural statistics show the variation in size of holdings and the changes in crops and livestock between 1935 and 1955 An interesting aspect is the continuous rise in sheep production, but there has also been a pattern of technical improvement and change in farm economy to meet the seasonal fluctuations in demand This is discussed in relation to the five regions of the area There are about 12,000 acres of woodland, about half planted by the Forestry Commission—largely conifer high forest Many factors, of course, determine tree growth, but it seems clear that good oak and elm are to be found on freely drained slopes of soils derived from mixed drift although falling short of conifers in yield production

Numerous figures and tables are of great assistance in assimilating the information presented, and several excellent photographs illustrate the outstanding features of the area in question

COMPARATIVE BIOCHEMISTRY OF THE LEGUMINOSAE

A SYMPOSIUM on "The Comparative Biochemistry of the Leguminosae", organized by the Plant Phenolics Group, was held at the John Innes Institute, Bayfordbury, Hertford, during September 10–11 The aim of the meeting was to bring together workers in diverse scientific fields but sharing a common interest in this group of plants The Leguminosae, which contains some 550 genera and 12,000 species, is, in economic importance, second only to the Gramineae, and members of the family contain a remarkably large number of interesting and unusual chemical constituents In his opening paper, N W Simmonds (John Innes Institute) reviewed the systematics of the family and summarized the many uses legumes are put to as foods, forages, timbers, gums, resins and tannins Dr R Cooper (Rothamsted Experimental Station), in dealing with root nodulation, pointed out that 90 per cent of the fixed nitrogen in the world had come from leguminous root nodules His review of the conditions required for successful nodulation by *Rhizobium* showed that many factors, including the occurrence of the correct host-symbiont specificities and the presence of the right kind of polysaccharide in the host roots, were involved

Chemistry may well be, in the future, of considerable value to the systematists dealing with legumes Its present contribution is slight, mainly because very few taxa have been thoroughly surveyed chemically Dr R E Alston and his colleagues in the University of Texas are therefore concentrating their efforts on a single genus, *Baptisia* Dr Alston illustrated his talk on this genus with pictures of the phenolic spots obtained on two dimensional chromatograms of leaf and flower extracts The patterns so obtained can be used not only to distinguish most of the eighteen or so species but also many of the interspecific hybrids Compounds which, at the moment, show more promise as taxonomic markers than the phenols are the free amino-acids Besides having the common protein amino-acids, legume seeds contain a range of unusual ninhydrin positive substances, such as canavanine, homoarginine, γ-hydroxyhomoarginine and lathyrine Dr A E Bell (King's College, London), in the next paper, showed that most species of *Lathyrus* could be divided into four groups, depending on their characteristic amino-acid patterns, species of *Vicia* could be divided in a similar manner

Few systematic surveys of alkaloids have been carried out in the legumes, so that no taxonomic inferences can yet be drawn from their distribution. However, three series of characteristic bases (the quinolizidines, the pyrollizidines and the *Erythrina* indoles) are present and, according to Dr. M. F. Grundon (University of Belfast), who provided the next paper, they could all arise from the same two precursors, Δ^1-piperideine and α-ketoglutaric acid, by similar biosynthetic pathways. In the last paper on nitrogenous constituents, Dr. D. Boulter (University of Liverpool) described recent progress on the separation of legume proteins. By using acrylamide-gel electrophoresis, he had been able to separate the albumin fraction of the field pea into more than twenty distinct components.

The second day of the meeting was devoted to phenolic constituents. One group of phenols, the isoflavonoids, occurs far more abundantly in the Leguminosae than in any other family, so that it was fitting that the first paper dealt with chemical studies on some recently discovered members of this group. Prof. W. D. Ollis (University of Sheffield) provided a fascinating account of the use of nuclear magnetic resonance spectroscopy for elucidating the structures of the complex phenols present in *Derris robusta*, *Piscidia erythrina* and species of *Dalbergia*. Dr. H. E. Nursten (University of Leeds) then described the hydrolysable and condensed tannins present in such plants as *Acacia melanoxylon* and *Robinia pseudacacia*. The legumes are an extremely rich source of flavonoids with unusual substitution patterns, and Dr. J. B. Harborne (John Innes Institute), in the next paper, summarized the various structural types present. He then referred to variability in glycosidic pattern, making the point that this sometimes showed correlation with systematics, as illustrated by surveys of the anthocyanins and flavonols of *Lathyrus*, *Pisum* and *Vicia*. Chromatographic patterns of phenolics in flower petals are also of interest at the variety level, Miss J. J. Corner and Dr. D. G. Rowlands (Unilever, Bedford) have found that broad bean varieties can be divided into two groups on the basis of their flavonol content. Beans are rich sources of oligosaccharides of the raffinose series, and Miss M. Walters (Royal Holloway College, London), in the last paper, described work on the biosynthesis of raffinose from uridine diphosphogalactose and sucrose in *Vicia faba*.

The meeting ended with a summary of the chemical aspects by Dr. E. C. Bate-Smith (Low Temperature Station, Cambridge) and of the taxonomic aspects by Dr. B. L. Turner (University of Texas). There was much lively discussion of these and other papers presented at the symposium. This was the first meeting of the Plant Phenolics Group to be held since the group decided to extend its scope to cover other plant constituents besides phenols, and its success underlined the fact that there is a very real need in Britain for an organization broadly devoted to phytochemistry.

J. B. HARBORNE

THE MOON'S PHOTOMETRIC FUNCTION

By DR. ROBERT L. WILDEY

Division of Geological Sciences, California Institute of Technology and Mount Wilson and
Palomar Observatories, Carnegie Institution of Washington and
California Institute of Technology

In the general case, for a flat diffuse-reflecting surface of a given normal albedo (ratio of true brightness to that expected from a non-absorbing Lambert scattering surface under the condition that the direction of illumination and observation are both perpendicular to the surface), the specification of surface brightness, B_λ, in units of the power of the illuminator is obtained with the knowledge of the three remaining degrees of freedom in the problem. These are the azimuthal angle between the illuminator and the observer, the angle of incidence, and the angle of observation, shown in Fig. 1 as μ, i and e respectively. In the case of the Moon an equally valid set of parameters would be the phase angle, α, the angle of elevation of the Sun, $A_\odot$, and the elevation angle of the Earth, $A_\oplus$, which are also shown in Fig. 1.

It follows that all lunar photometric data, when plotted in the four-dimensional space (B_λ, α, $A_\odot$, $A_\oplus$), should, within the observational error, define a 'surface'. Any tendency to abnormally large scatter about a 'surface' in such a plot could be due only to a non-unique scattering law (photometric function) for the lunar surface, or one which was 'polarized'. The latter possibility would derive from an anisotropic surface, that is, the scattering law would not be invariant to a rotational transformation of co-ordinates about the μ axis, and one additional degree of freedom would be introduced.

That the Moon's photometric function is fairly unique is suggested by previous photographic photometry, however, that ray material is a somewhat better backscatterer than most of the rest of the Moon is well known.

This article presents an additional simple observational test, in the case of the inner slopes of crater rims, of the double assumption that (1) the general photometric function of the lunar surface applies to the inner walls of crater rims, (2) the functional form of the photometric function which has been fitted to previous photographic data is correct.

In a review paper, Minnaert[1] has discussed comprehensively the history of photometric observations of the Moon. Except for photoelectric investigations of the integrated light (whole Moon), by Rougier[2] and Bullrich[3], the most widely accepted observations have been by pure photographic photometry, the susceptibility to systematic error of which leaves their reputation open to question, regardless of the skill of the observers involved.

It has been universally concluded that the strongest source of variation of the brightness of a given lunar feature is the variation in phase angle, which conclusion is not seriously questionable. It has also been concluded, however, that the form of the residual dependence on $A_\odot$ and $A_\oplus$ is in the form of a dependence on $h = f(\alpha, A_\odot, A_\oplus)$, and in particular that h is an angle defined locally on the lunar surface as the projection of angle e on the plane containing the vectors pointing toward the Sun and the Earth. h is shown in Fig. 1. This assumption follows from the conclusion by Minnaert[1] and Fessenkov[4] that, making allowances for differences in normal albedo, isophotes tend to coincide with lunar meridians. For a smooth spherical Moon, when the selenographic latitudes of the sub-solar and sub-Earth points are both zero, h equals the selenographic longitude of the particular point on the lunar surface. Hence the name 'brightness longitude' for h, even though h will vary with local strike and dip, regardless of the constancy of selenographic co-ordinates.

Eimer[5] has determined the Moon's photometric function, assuming it to depend only on a and h, from the photographic data of Fedoretz[6]. The result is a function, which, for a given phase angle other than zero, is a monotonic function of h over the range given

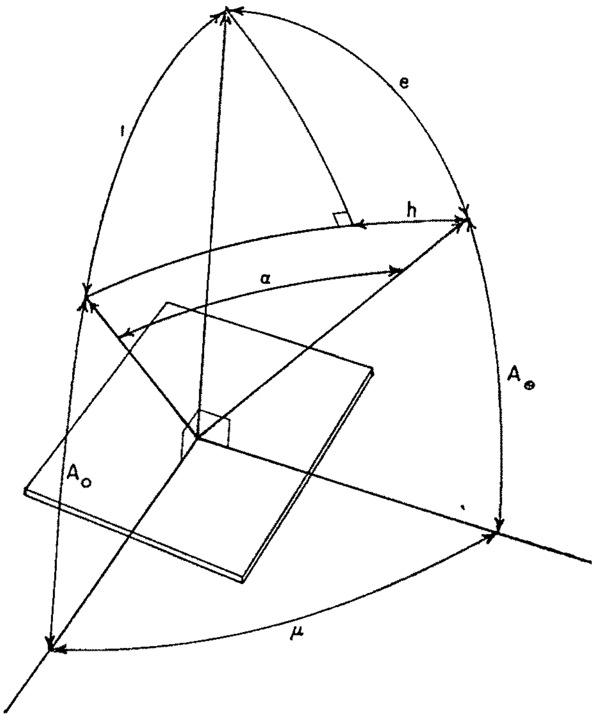

Fig 1 Diagram of angles orienting an element of lunar surface and the directions to the Sun and Earth. i is the angle of incidence, $A_\odot$, the elevation angle of the Sun, e, the angle of observation, $A_\oplus$, the elevation angle of the Earth, α, the phase angle, and μ, the azimuth difference between the Sun and Earth

When such a photometric function is applied to the illuminated portion of the inner slope of a crater rim which is casting a slight shadow on the crater floor, an interesting simple result is predicted If the vector pointed toward the Earth makes a small angle, σ, with the vector which points directly away from the centre of the Moon (normal to the hypothetical lunar surface of a perfectly spherical Moon), then the brightest point on the inner slope of the crater rim should lie nearly opposite the point on the rim which casts maximum shadow On the other hand, if σ is large, and unless α is very small, the point casting maximum shadow and the point of maximum brightness are connected by a lesser chord than a diameter As σ approaches $\pi/2$ the angular distance around the crater rim through which the point of maximum brightness travels, from the point directly opposite maximum shadow, is given by $\cos^{-1}$ ($\cot\kappa$ $\cot\alpha$), where κ is like σ except defined for the Sun, that is, the angle of incidence with respect to the local gravitational vertical rather than the normal to the local terrain Notice that this maximum angular travel is always an obtuse angle for phase angles less than $\pi/2$

We thus predict that shadowed craters at high latitudes should have their point of maximum brightness more nearly adjacent to the shadow, whereas craters near the equator should have shadow and maximum brightness on opposite sides There is a simple corollary which may be applied to a random collection of reasonably good photographs on which the resolution is good enough to make out some detail on the crater rims and for which the range of brightness thereon falls in the monotonic portion of the H and D curve It is that, assuming all craters to be round, for shadowed craters which appear round and for those which appear oval in which the shadow is symmetric about the minor axis of the oval, the rim point showing maximum brightness should be opposite the rim point casting maximum shadow, however, the greater the departure from both these conditions, the closer together on the rim the points casting maximum shadow and showing maximum brilliance tend to lie

This criterion has been applied to a group of photographs of the Moon including some printed from plates by Pease, some from the Moore–Chappel series, and some recent photographs taken by Herbig under extraordinary seeing conditions with the 120-in Lick reflector The results are shown in Fig 2 The outlines of many craters have been traced The line passing through each trace has been drawn through. (1) the point of maximum brightness, (2) the centre of gravity of the shadow image

Few extreme cases are shown, but nearly all those which should give slight departure from perfect bisection do, in weak support of an (α, h) dependent photometric function If one were trying to substantiate an (α, i) dependent photometric function one would look for a line which definitely cuts across the minor axis of the crater trace, but nevertheless appears nearly to bisect the crater. Crater 3 tends to show this slightly Crater 21 shows it a bit better and crater 30 is a good example of such an exception. The present simple method should not be regarded as having established the photometric function of the exceptions noted, but it has quickly revealed them as apt candidates for special, more quantitative investigation

One might, out of belief that all lunar slopes are gentle, conclude that shadowed craters are necessarily so near the terminator that the photometric function in their vicinity must have the limiting form, f (α) cos i, which Minnaert[1] has shown to be a corollary of the second law of thermodynamics and the observation that lunar luminance near the bright limb is nearly constant However, it has been shown[7,8] that the slopes in question are by no means gentle enough for this criticism to be levied

In conclusion, it seems reasonable to say that in the majority of cases where differences in the predictions of an (α, h) and (α, i) dependent photometric function are small, the observations favour an (α, h) dependent function However, two exceptions are rather strong in their deviations. It is thus suggested that either (1) most inner crater rims have an (α, h) dependent photometric function, while a few cases have (α, i) dependence, or (2) all crater

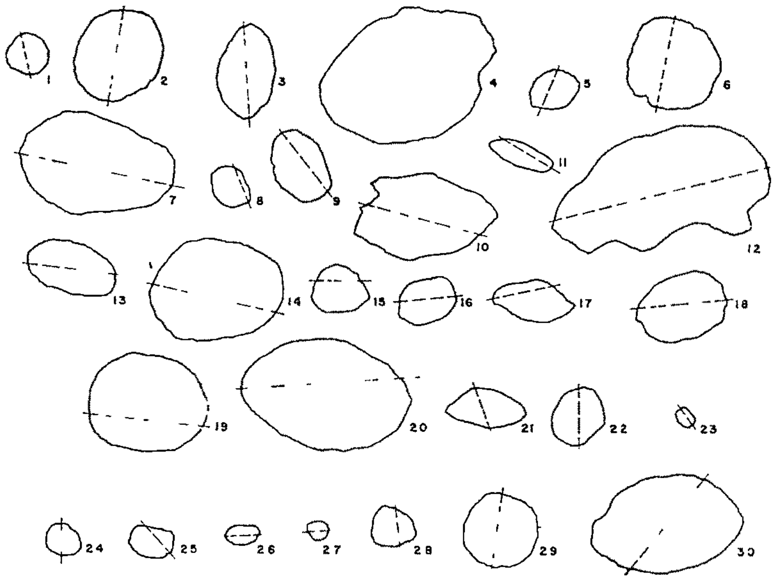

Fig 2 Traces of the projected outlines of craters Dashed lines pass through, (1) the centre of gravity of the inner shadow, (2) the point on the crater rim's inner slope which is brightest

rims have a non-degenerate (α, i, e) dependent photometric function which we do not yet know, or (3) perhaps only one or two cases showing fairly strong deviation from that predicted by an (α, h) dependence are significant and the more minor departures represent the 'noise-level' of the present method The third possibility would be compatible with the second possibility or vice versa of the first

USE OF GAS CHROMATOGRAPHY FOR THE DETECTION OF LIFE ON MARS

By VANCE I OYAMA

Life Detection Systems Branch, Exobiology Division, Ames Research Center,
National Aeronautics and Space Administration, Moffett Field, California

THE technique of gas chromatography as applied to the identification of pyrolysis products of biological material has been advanced earlier as a means of life detection on Mars[1,2] Preliminary investigations as submitted here confirm in part the feasibility of this concept

The premise on which this concept is based originated from the fact that terrestrial life is an aggregate of carbonaceous macromolecular structures as well as a lesser mass of monomeric organic substances, the latter arise as intermediates in the syntheses of the macromolecules or by-products of metabolic processes The proteins, polysaccharides, and nucleic acids which represent macromolecular structure are composed of basic building blocks such as the amino-acids, monosaccharides, lipids, purine and pyrimidine bases These constituent substances are distributed universally among living materials, and the essential components of the protoplasm of life require that critical proportions of these basic building blocks be maintained either by assimilation from the environment or manufactured by the organism

The simple technique of thermal degradation has been applied to the analyses of chemical structure (The literature is replete with references too numerous to iterate) However, in a complex organic aggregate such as life, the pyrolysates from thermal degradation present a relatively difficult task of determining the original contributing structures Nevertheless, it is possible to present a chromatographic picture (such as has been described in paper chromatography in the two-dimensional display of peptides for the elucidation of protein structure) which could similarly describe the presence of life

Freshly isolated, but unidentified, micro-organisms were grown in trypticase soy broth under aerobic conditions at 30° C These were gathered during log phase of growth, washed with distilled water several times, and lyophilized to dryness

A single strain of micro-organism was used for determining the optimum temperature of pyrolysis which would reveal the major amount of volatile components of thermal breakdown as determined by a hydrogen flame detection device from gas chromatography column separations Since organic substances were of particular interest, this type of detector, incorporated in the Perkin–Elmer model 800, was used for this purpose 0 12 in × 12 ft column of 15 per cent '*SE* 30' on 60/80 mesh chromasorb *W* was maintained isothermally at 200° C The flow of gas was 80 ml /min

The pyrolysis chamber was a stainless-steel loop attached on to a linear 6-way valve, paired with another linear valve, which permitted, initially, evacuation of the sample loop, filling of the pyrolysis chamber with inert helium atmosphere, pyrolysis under closed system, and sweeping of the pyrolysis chamber into the flowing gas system directed into the columns The valving and tubing between the pyrolysis chamber and column were maintained at 125° C during the course of analysis Mass of the components appearing at the detector was measured by an Infotronics digital 'readout' system A weighed sample of material (10–200 µg) was funnelled into the sample loop and a heat pretreated fibre-glass cordage was inserted into the sample loop to prevent particulate matter from entering the critical valving area A pair of heated nickel plates, the temperature of which was regulated by a temperature controller and held together by spring action, was slipped over the loop making direct thermal conductive contact with the stainless steel sample loop

Pre-selected periods of time for various temperatures were utilized to determine the efficacy of residence time and temperature to give the greatest number of products Fig 1 shows that the total integrated products sensed at the detector are a function of these two parameters

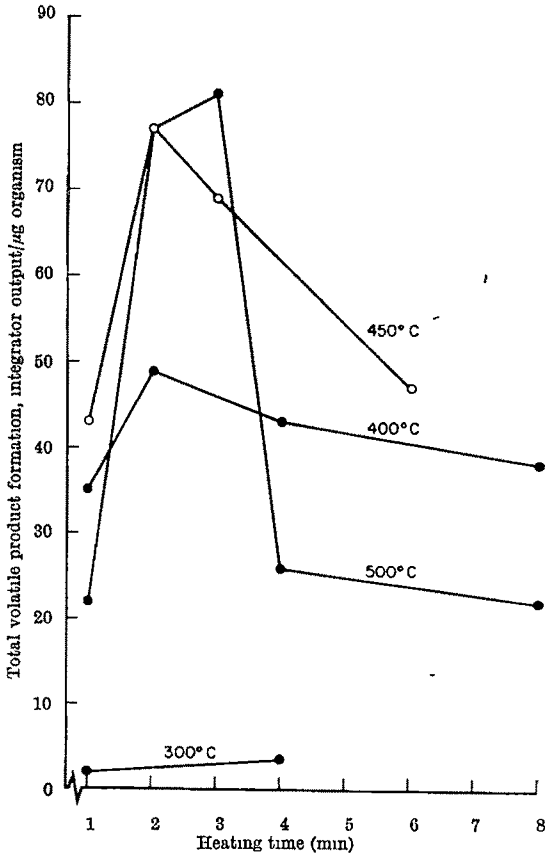

Fig 1 Comparative mass of volatile constituents formed at 4 temperatures for various times

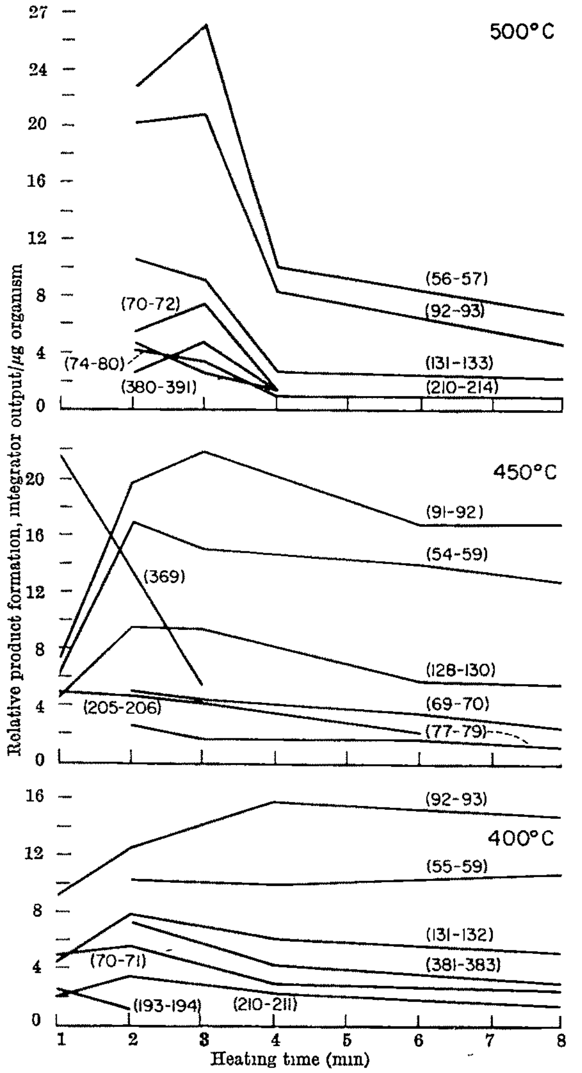

Fig 2 Products formation from dried micro-organisms as a function of temperature and residence time In brackets, retention time of integrated product (sec), range, 3 samples

No significant products are produced at temperatures of 300° C Exposure for 4–8 min will tend to decrease the total mass of substances Optimum temperature and residence time were 450° C or 500° C for 2 min It is not indicated, but to be noted, that the temperature within the stainless steel tubing took approximately 45 sec to attain 450° C

Fig 2 shows that the volatile substances produced by thermal degradation tend in turn to be degraded further Components of thermal degradation as determined by retention times show peak production at various times, for example, a component of retention time 56–57 sec (uppermost curve) is produced maximally at 3 min residence time for the specified temperature of 500° C The amount of product so produced will decrease as time of residence is increased It is to be assumed that synthesis of a thermal product is concurrently in progress with its degradation. The accumulated products of thermal decomposition represent only the thermal product which is measurable at the instant that the vapours are swept into the column The figure also shows that certain products are decomposed rapidly in time, while others reach a maximum at 4 min and appear to be stable at these temperatures Others, on the other hand, reach a maximum yield and degrade relatively slowly The figure shows the importance of reproducing the exact conditions of pyrolysis so that repeatability in terms of relative peak heights may be obtained

In order to ascertain as many of the products of thermal decomposition as is possible with a single system, a 0 010-in capillary column 300 ft long, coated with diethylene glycol succinate polyester, was temperature programmed for the analyses of some micro-organisms isolated from soils Typical results are indicated in Fig 3*A* It can be seen that under these reproducible conditions during linear temperature programming, the chromatographic peaks descriptive of the retention products occur with a periodicity common to all the organisms There are differences in peak-height relative to adjacent peaks, but the chromatograms indicate that thermal decomposition products of micro-organisms can be displayed in a fashion to show equivalence The relative peak-heights in each separate chromatogram show differences and may indicate differences in the relative amounts of precursor organic substance

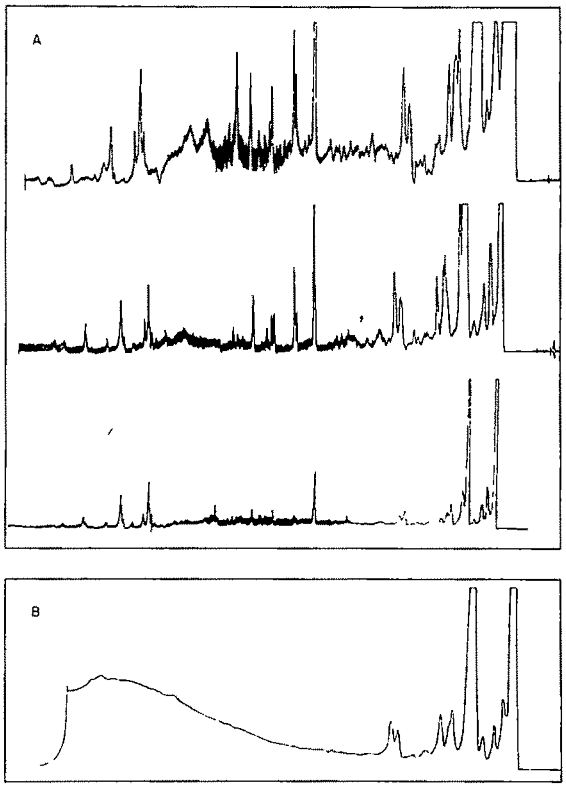

Fig 3 Comparative chromatograms of (*A*) three isolated soil micro-organisms, (*B*) of crystalline bovine albumin

Fig 3*B* shows the pyrolysate chromatogram of crystalline bovine albumin under similar conditions It is to be noted that similar patterns corresponding to early appearing chromatographic retention times of the micro-organisms are reproduced It is not altogether surprising, considering the original premise, to find similar patterns from proteins whether they be of plant or animal origin.

Further work is in progress to determine what these pyrolysate products are, the determination of what precursor organic substances are involved, as well as comparative chromatograms of micro-organisms as an approach to taxonomic differentiation

I thank Mr George Hotz for his contribution toward the design of the linear valving, as well as the pyrolysis heater systems, and Mr Frank Morrelli for his contribution of microbial inoculation sources

POLYPHASE FOLDING IN THE CALEDONIDES SOUTH OF THE SCOTTISH HIGHLANDS

By D. G. HELM, B. ROBERTS and Dr. A. SIMPSON

Department of Geology, Birkbeck College, University of London

THE high degree of structural complexity displayed by the Highland schists has long been known. Since the brilliant observations by C. T. Clough[1] in Cowal and the classic investigations by Sir Edward Bailey in the south-west and central Highlands, it has been apparent that the Caledonian architecture of this terrain has resulted from the impress of several, successive phases of orogenic movement.

During the past decade, detailed work by many workers[2-6] in various parts of the Moine and Dalradian Series has served to emphasize the polyphase nature of their Caledonian tectonics. Early acute or isoclinal flexures, often recumbent, have been re-folded on all scales by later generations of folds, usually with a more open profile, resulting from subsequent orogenic pulses. Each fold-system is generally accompanied by the development of a syngenetic, axial-plane foliation. In the earliest acute to isoclinal folds the latter has the character of a slaty cleavage or schistosity in pelite. On this primary foliation are successively impressed the strain-slip cleavages which accompany the later generations of flexures. This polyphase sequence of folds and cleavages is not confined to the more highly metamorphosed strata but is equally well developed in the mildly altered Dalradian sediments of the Highland border and Loch Awe region.

In contrast to the lengthy tectonic chronology of repeated folding displayed in the Scottish Highlands, the considerable volume of literature dealing with the remainder of the Caledonides to the south has suggested a much simpler orogenic programme. In such regions of deformed Lower Palæozoic strata as the Southern Uplands, Lake District, Wales and south-east Ireland, only a single phase of severe Caledonian folding, accompanied by an axial-plane cleavage, has been described. This fold-system, and the related cleavage, is steeply inclined with a predominant Caledonoid trend. The metamorphic alteration which accompanies the deformation of these fossiliferous strata is, of course, slight.

More or less centrally placed in the Irish Sea region, and surrounded by the above spreads of Lower Palæozoic strata, lies the Isle of Man possessing as its geological foundation the thick Cambrian pile of the Manx Slate Series. Within these strata Simpson[7] has recently demonstrated the existence of Caledonian polyphase tectonics which attain a scale and complexity comparable with parts of the Scottish Highlands. Three distinct phases of tectonic movement (F_1, F_2, F_3) each formed large-scale folds, a suite of congruous minor flexures and an axial-plane cleavage (S_1, S_2, S_3). The major and minor structures formed during the later phases deform those which originated earlier.

The F_1 folds are acute in profile and the accompanying S_1 is a flow or slaty cleavage in pelite. The early axial planes and S_1 are steeply inclined with a Caledonoid trend and for the most part the flexures plunge to the north-eastern and south-western quarters. The later F_2 and F_3 folds possess a more open, right-angled style and the accompanying S_2 and S_3 are strain-slip cleavages which were successively impressed on the complex pile. The F_2 flexures usually display Caledonoid plunges, their axial planes and S_2 are characteristically flat-lying or gently inclined. The axial planes of the F_3 folds and S_3 dip steeply to the north-eastern quarter, these latest plications always plunge steeply. Large-scale Caledonoid flexures of F_1 and F_2 age embrace the whole Island.

Following the recognition by Simpson of Caledonian polyphase folding and cleavage in the Isle of Man, research by us in the Lake District and North Wales has shown that comparable deformation is also developed in Lower Palæozoic strata of the mainland.

North Wales. Throughout North Wales the predominant fold-system resulting from the Caledonian orogeny possesses steep axial planes and is accompanied by a syngenetic axial-plane cleavage. In his tectonic summary of North Wales, Shackleton[8] has emphasized that, while displaying some variation in orientation, these structures are generally steeply inclined towards the north or west. This southerly-to-easterly vergence of the cleavage and the parent folds reflects the direction of translation of the higher layers in the sedimentary pile relative to those below during the formation of the fold-system. The intensity of these structures is greatest in the north-west towards Anglesey, towards Shropshire in the south-east the degree of deformation decreases.

During a volcanological examination of the Caradocian ignimbrite sequence in the Llwyd Mawr plateau, south-east Caernarvonshire, it became apparent to Roberts that the associated sediments occasionally show the impress of more than one phase of Caledonian deformation. In this area, as elsewhere in North Wales, the dominant, earliest (F_1) folds are steeply inclined to the north-western quarter and the accompanying axial-plane cleavage (S_1) usually has the character of a flow cleavage in pelite.

Sporadically, however, two subsequent generations of more open flexures (F_2 and F_3) deform the earlier S_1 and are accompanied by axial-plane strain-slip cleavages (S_2 and S_3). The F_2 folds display a low Caledonoid plunge and their axial planes, together with the related S_2, possess a gentle inclination, usually to the south-east. The axial planes of the later F_3 folds, and the accompanying S_3, dip steeply to the east-north-east and the flexures possess a steep to vertical plunge trending at 300°–320°.

The F_2 and F_3 folds are only mildly and sporadically developed in the Llwyd Mawr area. They are mesoscopic structures usually only a few inches across, though larger F_2 flexures with amplitudes up to 3 ft. have been observed on the western slopes of Mynydd Tal-y-mignedd. The later structures tend to be confined to pelite. For example, they have been observed in Cambrian (Ffestiniog) slates, in the Maesgwm Slates (Llanvirn) and in the Pennant Slates of Cwm Pennant (? Arenig).

Observations made by Roberts and Simpson at many other widespread localities in North Wales have shown that, while the steep F_1 folding and cleavage (S_1) remain pre-eminently responsible for the deformation of the Lower Palæozoic strata, the later F_2 and F_3 structures are sporadically developed in numerous places within Caernarvonshire and Denbighshire.

Consideration of the available evidence suggests that the sporadic F_2 folding in North Wales forms only a minor element of the Caledonian architecture and does not assume major proportions. The existence of large-scale F_2 folds would be reflected in the existence of broad Caledonoid belts, measured in miles across, within which S_1 would display a rotation through the vertical to a south-easterly inclination. Such belts would represent the short limbs of major F_2 fold-pairs Throughout North Wales, as Shackleton[6] has emphasized, S_1 retains a predominant steep northerly to westerly dip and reversals of the type described do not appear to be extensively developed

A possible exception is in north Denbighshire, where Boswell[9] has recorded the occurrence of a 'cleavage-fan' in S_1 extending eastwards from the Conway valley to the Clwydian Range Along a line lying 6–13 miles from the coast S_1 passes rapidly through the vertical and assumes a southerly dip which is retained for several miles farther north It seems possible to us that this 'fanning' may be due to large-scale F_2 flexuring, the question requires further investigation

As has been pointed out by Shackleton[6], one of the most obvious tectonic features in North Wales is the arcuation through 90°, convex to the north-west, in the trend of S_1 and the parent fold-system This deflexion embraces the whole of North Wales It takes place round a north-west–south-east axial trace running from the Menai Strait to Long Mountain in Shropshire The only interruption in the continuity of this open hinge is a sinistral offset of several miles apparently due to transcurrent movement along the Bala fault which is clearly portrayed on Shackleton's cleavage map[6] In the west (south Caernarvonshire) and south-west (Harlech region) the F_1 structures are aligned due north or a little east of north, to the north-east and east in Denbighshire the trend has swung round to the east or a little south of east

The arcuation is sharpest on the north side of the Berwyns and is clearly outlined on the 'ten-mile' geological map by the deflexion of the various Lower Palæozoic formations and major F_1 fold axial traces For example, on entering the deflexion, the core of the Llandderfel syncline (northward continuation of the Central Wales syncline) curves rapidly through 90° from its north-north-east trend and, continuing as the Llangollen syncline, preserves a trend a little south of east until it plunges below the Lower Carboniferous escarpment Five miles to the south-east, the complementary Berwyn anticline undergoes a comparable right-angled deflexion Farther north[6] the regional arcuation of the F_1 structures between south Caernarvonshire and Denbighshire is more gradual

The regional deflexion of the Caledonian structural pattern in North Wales has previously been interpreted as an arcuation of the orogenic belt presumably formed at the same time as the dominant (F_1) fold-system

Four miles south-west of Corwen, around Llandrillo, the deflexion of bedding and S_1 through 90° occurs rapidly and can be followed out within a few miles We have recently examined this tract, in the hinge of the arcuation, and have observed the presence of a strong S_3 in the slates which intersects and lineates both bedding and S_1 This strain-slip cleavage dips steeply to the north-eastern quarter and its north-westerly trend is parallel to the axial trace of the regional arcuation in the earlier structural elements The F_3 lineation and occasional small-scale, congruous F_3 crumples have a steep north-westerly plunge These F_3 structures tend to die out to the east and south-west away from the hinge of the arcuation and are clearly related to it in origin Farther north where the regional deflexion is more open, comparable F_3 structures are sporadically developed in Caernarvonshire and Denbighshire, but are especially noticeable around Conway, which also lies close to the crest of the deflexion

We conclude that the regional arcuation of the Caledonides in North Wales was not developed synchronously with the severe F_1 movement-phase but outlines a large-scale flexure of F_3 age This *North Wales antiform* has a steep-to-vertical axial plane and its north-westerly plunge is reflected by the convexity of the arcuation it has produced in the earlier structural elements Its style and orientation are identical to the related minor F_3 folds on its flanks and hinge S_3 has an axial-planar relationship to the parent flexure

The style and disposition of the North Wales antiform are similar to the several large-scale F_3 flexures recently described by Simpson[7] in the Isle of Man In particular, the resemblance to the Sulby antiform, the largest of the Manx structures, is especially striking The latter embraces the northern part of the Isle of Man and causes an identical arcuation to the east or east-south-east in the Caledonoid trend of the pre-existing linear and planar structures as its Welsh counterpart The upwarp of the core of the Caledonoid F_1 Isle of Man syncline by the Sulby antiform has caused a conspicuous plunge culmination in the early structures

The flexing of the F_1 Llandderfel–Llangollen syncline by the North Wales antiform has resulted in an identical reversal in the plunge of the early system Immediately west of the F_3 hinge the Llandderfel syncline has an overall plunge to the south-west On the opposite flank of the antiform the Llangollen syncline retains an easterly plunge until it disappears below the overlying and unconformable Carboniferous Limestone

The Taconic (end-Ordovician) folding of the Lower Palæozoic sediments in Shropshire dies out rapidly to the north-west and, as Shackleton[8] had emphasized, the pronounced deformation by folding and cleavage in North Wales must be assigned to the late Silurian–early Devonian interval

The observations made by us have shown that the orogenic chronology displayed by the Caledonides in North Wales is more complex than previously envisaged Not merely one but three phases of folding, each accompanied by cleavage-generation, can be distinguished This polyphase tectonic history can be summarized as follows

(1) *First movement-phase* (F_1) The F_1 fold-system, accompanied by the axial-plane S_1, was formed The large-scale structures produced have been admirably described by Shackleton[6] The F_1 structures pervade the Lower Palæozoic pile from the Cambrian at the base to the highest Ludlow (Dinas Bran) beds preserved in the core of the Llangollen syncline This was the most severe episode of Caledonian deformation in North Wales, though its imprint gradually declines towards Shropshire

We believe that the F_1 system originally possessed a Caledonoid (north-east–south-west) trend and a south-easterly vergence reflecting the direction of relative translation of the higher layers in the pile during folding

(2) *Second movement-phase* (F_2) The effect of this phase was relatively mild with the sporadic generation of mesoscopic folds accompanied by the gently inclined, axial-plane S_2 Major F_2 folding appears to be absent, though the 'cleavage-fan' in S_1 of north Denbighshire may represent F_2 flexuring on a larger scale

(3) *Third movement-phase* (F_3) Compression was applied to the folded pile along a Caledonoid line The large-scale North Wales antiform was produced as a cross-fold together with the sporadic generation of congruous minor F_3 folds and the steep axial-plane S_3 From their pre-existing Caledonoid (north-east–south-west) trend, the earlier structural elements (predominantly F_1) were flexed by the antiform into the conspicuous arcuation which is so obvious over the whole of North Wales The North Wales antiform is by far the largest F_3 flexure recognized by us so far in the Irish Sea region

Lake District A structural investigation being carried out by Simpson in the main tract of the Skiddaw Slate Series has shown the polyphase nature of the Caledonian deformation to which these Arenig sediments have been subjected The sequence of structures impressed is identical to that already described[7] in the Isle of Man The same three episodes (F_1, F_2, F_3) can easily be distinguished and the successive generations of mesoscopic structures are similar in style and orientation to their Manx contemporaries

The earliest F_1 folds are acute and display a Caledonoid trend, their axial planes, and the accompanying S_1, are steeply inclined Two subsequent pulses of movement produced the more open, right-angled F_2 and F_3 fold-systems with their related axial-plane strain-slip cleavages The F_2 structures retain their characteristic flat-lying to gently inclined disposition and Caledonoid axial plunges The F_3 flexures form a suite of cross-folds, their axial planes, and accompanying S_3, dip steeply to the north-eastern quarter

This sequence of repeated folding and cleavage-formation is clearly evident throughout the broad expanse of the Skiddaw Slates, though the phenomenon has received no mention in the previous literature For example, the superimposition of F_1, F_2, and F_3 structures can be clearly seen in the crags above Whinlatter Pass and on the flanks of Skiddaw itself

In the south-western corner of the Lake District the Skiddaw Slates crop out from below the overlying Borrowdale Volcanic Series to form a large inlier centred on the mountain of Black Combe In the course of a detailed stratigraphical and structural study of these strata, Helm has also recognized a comparable tripartite (F_1, F_2, F_3) programme of Caledonian deformation In addition he has shown that the Caledonian architecture of Black Combe differs in certain respects from that displayed in the main Skiddaw outcrop twenty miles farther north

The trend of the steep F_1 folds, and related S_1, is north-south and their original attitude was vertical Moreover, the F_2 flexures are usually more acute, their limbs enclosing an angle of 40°–60° The strong axial-plane S_2 dips consistently at 20°–40° north-west in contrast to the rather variable azimuth of this gentle structure farther north As a result of the pre-existing northerly grain of the F_1 system, the F_2 folds and second linear structures plunge at 30°–40° to the north-western quarter Minor F_3 folds, and accompanying S_3, deform the structures of the earlier movement-phases and retain the usual steep north-easterly disposition

Conclusion. It will be clear from the foregoing account of our observations in the Isle of Man, North Wales and the Lake District that the Caledonian tectonic chronology of these areas is more complex than previous workers have envisaged The detailed results of our work on the mainland will be published later The purpose of the present contribution is to emphasize that polyphase Caledonian folding with its accompanying sequence of superimposed cleavages is by no means confined to the metamorphic terrain of the Scottish Highlands forming the northern part of the Caledonides It seems inevitable to us that subsequent research will reveal a comparable sequence of folding and cleavage in other parts of the Irish Sea region

It may be emphasized that in each of the three areas we have examined the sequence of movement-phases, together with the style and orientation of the resultant structures, is similar Acute, steep folding (F_1) with a Caledonoid trend (locally veering to the north in Black Combe) forms a tectonic basis which is successively deformed by more open flexures round gently inclined, Caledonoid axial planes (F_2) and by steep cross-flexuring (F_3) with a north-westerly trend

EFFECT OF SMALL PROTRUSIONS ON MASS TRANSPORT TO A ROTATING-DISK ELECTRODE

By G. T. ROGERS and K. J TAYLOR

Isotope Research Division, Wantage Research Laboratory, U.K Atomic Energy Authority

THE rotating-disk electrode is increasingly being used to examine electrode reactions at known rates of transport of reactants to the electrode surface. An essential result of Levich's[1] theoretical treatment of transport to the electrode is that, for a reaction where the rate is purely transport-controlled, reaction conditions are uniform over the area of the disk Several workers, when using the electrode to study metal deposition[2,3] and dissolution[4–6] reactions, have found spiral patterns on their disks The presence of these patterns shows that, in practice, conditions may not be uniform over the disk The causes of spirals and their effects on the rate of transport of reactants to the electrode surface are therefore of interest This article describes an investigation of these aspects of spiral patterns in a study of metal deposition on disks used at Reynolds numbers of about 10^4 The results indicate that the spirals are traces of the wakes behind small protrusions, such as burrs or gas bubbles, on the disk There is no evidence of boundary layer separation or vortex formation in the wakes The formation of vortices would result in rates of transport greater than those calculated from the Levich theory Experiments on the transport-controlled reduction of coumarin during nickel electrodeposition have shown that the overall rate of transport to a disk with many spirals did not differ significantly from the rate to a disk which showed no spirals

Spirals produced by hydrogen evolution A rotating disk electrode has been used to study the effects of coumarin on the electrodeposition of nickel[2]. Deposits plated from a Watts-type nickel plating solution, which contains no coumarin, had a uniform matt appearance Deposits plated under identical conditions, but from Watts's solution containing coumarin showed spiral patterns on the electrode Fig 1 shows a typical pattern These patterns were made up from fully bright, darker areas, and hazy areas of deposit superimposed on a slight pattern in relief There was a minute hole in the deposit at the origin of each spiral and a microscopic defect in the original disk surface at each origin Coulomb balances for the cathodic reactions showed that coumarin markedly increased the amount of hydrogen evolved With coumarin present bubbles of hydrogen could be seen to be flung off the disk during deposition No bubbles could be seen during deposition without coumarin Coumarin thus appears to favour the evolution of hydrogen from defects in the surface As the spirals are formed under conditions where the rate of coumarin reduction is transport-controlled they reflect local changes in the transport rate to the electrode The appearance of the spirals suggested that they might be traces of the wakes of hydrogen bubbles growing at these points, the bubbles acting as protrusions attached to the disk To test this the patterns produced by known protrusions have been investigated.

Spirals produced by burrs Nickel sheet was found to contain less defects than the nickel rod used to prepare electrode disks for earlier work Using disks of about 2-cm diameter made from this sheet, deposits showing only

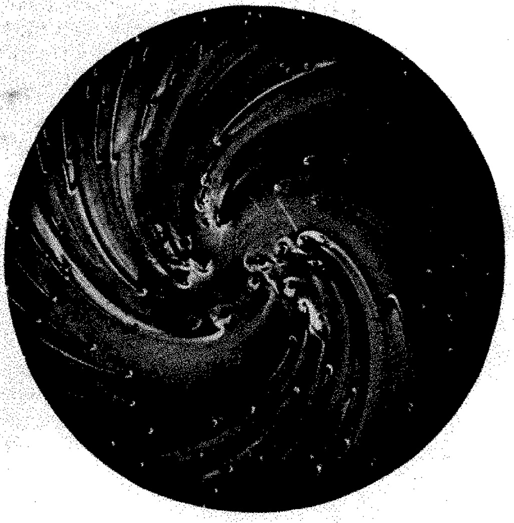

Fig. 1. Photograph of a typical pattern of spirals nickel plated from a Watts solution containing coumarin. Dark areas correspond to fully bright plate (× c. 3·3)

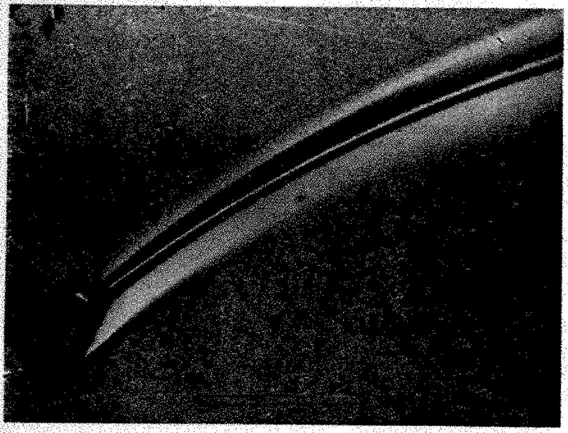

Fig. 2. Photograph of burr and its spiral

1 or 2 spirals could be obtained. Protrusions such as a 400-μ diameter insulating bead stuck on the disk or a flush hole of about 350-μ diameter with a bubble of hydrogen maintained in it gave spirals generally similar to, but much less well defined than, those obtained on smooth disks. Smaller protrusions gave better-defined spirals. The most satisfactory protrusions for further study were the burrs raised by pressing a sharp scriber point against the disk. Disks with burrs were plated using Watts's solution containing coumarin. A disk with 56 burrs was prepared and plated. There was a spiral associated with each burr and a few spirals similar to those in Fig. 1 resulting from hydrogen bubbles. Fig. 2 shows a typical burr and its spiral. No indication of vortex formation or turbulence was found in any of the spirals examined. The heights of burrs were estimated by focusing a microscope on the peaks of burrs and on the deposit near their bases using a microscope with a calibrated fine focus.

Suppose that a protrusion of height h produces a spiral which is the trace of the wake produced by a protrusion in the fluid at height h above the disk. This height can be deduced from the curvature of the spiral. Cochran[7] has described the flow near the disk using co-ordinates r, θ in the plane of the disk and $\zeta = \left(\frac{\omega}{\nu}\right)^{\frac{1}{2}} z$ normal to the disk. ω is the angular velocity of the disk and ν the kinematic viscosity of the fluid. The radial, angular and normal components of velocity u, v, w are given by:

$$u = r\,\omega\,F \quad v = r\,\omega\,G \quad w = (\nu\omega)^{\frac{1}{2}}H$$

where F, G, H are functions of ζ tabulated by Cochran. If u', v', w' are the equivalent components relative to the disk:

$$u' = u,\ v' = r\omega(1-G),\ w' = w$$

for values of $\zeta < 1{\cdot}0$ and $r > 0{\cdot}2$ cm w' is small compared with u' and v' so that the path of the fluid in the plane

$$\zeta = \left(\frac{\omega}{\nu}\right)^{\frac{1}{2}} h$$

can be considered as projected on to the disk. The path is given by $r = r_0 \exp \frac{(F)}{(1-G)} \cdot \theta$ the ratio $\frac{F}{(1-G)}$ being determined by ζ. Paths for different values of ζ were drawn on tracing paper and fitted to the spirals on an enlarged photograph of the disk. The mean height of 8 burrs which had clearly defined spirals, measured microscopically, was $10 \pm 1\mu$. Their spirals corresponded with $\zeta \leq 0{\cdot}1$. One larger burr was $21 \pm 1\mu$ high and had a spiral with ζ slightly less than 0·2. The disk was rotated at 980 r.p.m. and $\nu = 1{\cdot}1 \times 10^{-2}$ strokes, so that $\zeta = 0{\cdot}1$ and 0·2 correspond to heights of 10 and 20μ respectively.

The resultant velocity relative to the disk of fluid in a plane ζ at distance r from its centre is:

$$V(\zeta) = r\omega[F^2 + (1-G)^2]^{\frac{1}{2}}$$

If the height of a protrusion is taken also as a characteristic length for it a Reynolds number for flow near a protrusion is:

$$R = \left(\frac{\omega}{\nu}\right)^{\frac{1}{2}} \zeta r[F^2 + (1-G)^2]^{\frac{1}{2}}$$

For a 10-μ high protrusion on a disk rotating at 980 r.p.m. $\zeta \doteqdot 0{\cdot}1$. Then $R = 6$ for a protrusion 0·8 cm from the centre.

The incorporation of carbon from coumarin in deposits which showed bubble spirals and on disks with burrs has been investigated autoradiographically on deposits from solutions containing coumarin labelled with carbon-14. Fig. 3 is an autoradiograph of the pattern shown in Fig. 1. The lighter areas correspond with lower incorporation of carbon. A comparison of Figs. 1 and 3 shows that incorporation is lower within the spirals. Spirals produced by burrs showed a similar lower incorporation but without the very small areas of higher incorporation at their origins.

Conclusions. The spirals indicate that burrs and gas bubbles produce a disturbance of the flow near them which is stable and has stream lines which are very close to those of the theoretical laminar flow near the disk. There

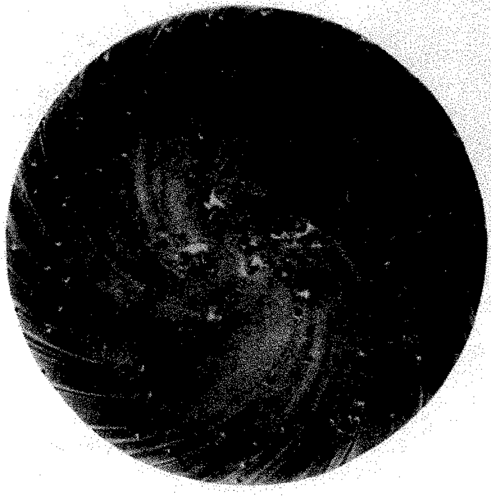

Fig. 3. Autoradiograph of the disk shown in Fig. 1. The coumarin used was labelled with carbon-14. Radioactive areas appear dark (× c. 3·3)

is no sign of vortex formation in the spirals and the Reynolds number evaluated here is an order of magnitude less than that for transition from laminar flow to a vortex street round a circular cylinder[8] or past a protrusion[9]. It seems most likely that the incorporation, in a deposit, of carbon from coumarin will increase as the rate of coumarin transport to the electrode increases. Hence the autoradiographic results indicate a lower rate within spirals than on the uniform surface. This is to be expected if the flow around protrusions was laminar and is the reverse of that to be expected if a vortex with its axis parallel to the disk were present. The flow around the protrusions, therefore, appears to be completely laminar with conditions far from those which would produce vortices. Under these conditions, the difference between the total rate of transport to a disk with spirals and a uniform disk should not be greater than and is probably less than the difference between the uniform areas on the two disks. Any relief in the spirals will slightly increase the available area of the electrode and hence the total rate of transport. This will be counteracted by the lower rate within spirals. The magnitude of the error in a measurement of the rate of a transport controlled reaction due to the presence of spirals is shown by comparing the rates of coumarin reduction at the disk with 56 burrs and one without burrs under conditions where the rate is known to be transport-controlled[2]. A difference of more than 5–10 per cent in rate would have been significant. There was no significant difference in the two rates, which were in agreement with rates calculated from the Levich theory.

ELECTRICAL PROPERTIES OF PYRITE-TYPE AND RELATED COMPOUNDS WITH ZERO SPIN MOMENT

By DR. F. HULLIGER
Cyanamid European Research Institute, Cologny, Geneva

A LARGE number of transition element compounds of composition TX_2 crystallize in the pyrite, the marcasite or the arsenopyrite structure. In these structures the anions are tetrahedrally surrounded by one anion and three cations, whereas the cations are located in half the octahedral holes formed by the anion sublattice. If, therefore, X and Y denote di- and tri-valent anions, respectively, then non-metallic polycompounds are possible with ionic formulæ $T^{2+}(X_2)^{2-}$, $T^{3+}(XY)^{3-}$ or $T^{4+}(Y_2)^{4-}$. The occurrence of non-metallic properties requires that the chemical bonds be saturated and that all d electrons not involved in σ bonds be localized. These extra electrons not only influence the electrical properties but also the crystal structure. In the pyrite and cobaltite structure the octahedral holes occupied by cations are essentially regular, whereas the marcasite and the related arsenopyrite lattice readily allow for strong distortions and the formation of additional cation–cation bonds. As a consequence, cations with high-symmetry d configurations, such as $d\varepsilon^3 d\gamma^2$, $d\varepsilon^6$, $d\varepsilon^6 d^1_{\text{metallic}}$ and $d\varepsilon^6 d\gamma^2$, are encountered in the pyrite and in a few cases, for example FeS_2, $FeSe_2$, in an ideal marcasite structure. Cations with asymmetrically filled $d\varepsilon$ sub-shells occur only in the strongly distorted marcasite (Loellingite type) and arsenopyrite lattice. No compounds such as MnP_2 or CrAsS with cation configurations $d\varepsilon^3$ are known[1]. The cation configuration most favourable for the occurrence of the pyrite structure is $d\varepsilon^6$. Moreover, this non-magnetic configuration also favours semiconductivity, but does not guarantee it, as will be seen here. The prototype of the $d\varepsilon^6$ pyrites is FeS_2, and its semiconducting properties are well known. Since replacement of the 3d by either a 4d or a 5d cation normally enhances the non-metallic character[2,3] we expected the isomorphous ruthenium and osmium dichalcogenides to be semiconductors as well. This expectation was substantiated by measurements of the electrical resistivity. In agreement with the postulated $d\varepsilon^6$ cation configuration, all compounds proved to be diamagnetic. My data are collected in Table 1.

Semiconductivity in $T^{3+}(XY)^{3-}$ compounds of the cobaltite type has recently been discussed[4], so that we need not consider it here.

To get the configuration $d\varepsilon^6$ in a phosphorous-group compound TY_2, we have to choose the cation T from the nickel group. Indeed, $PdAs_2$, $PdSb_2$, PtP_2, $PtAs_2$, $PtSb_2$ and α-$PtBi_2$ are known to crystallize in the pyrite structure. I have found the following additional mixed pyrite phases:

PdAsSb a = 6·265 Å
PtPAs a = 5·842 Å
PtSbBi a = 6·570 Å

According to the rules[2,3] holding for transition element compounds, we expect non-metallic properties above all in the compound with the heaviest cation and the lightest anion, that is, in PtP_2. As seen from my resistivity measurements, all the compounds down to $PtSb_2$ turned out to be non-metallic (see Table 2).

In PtSbBi the energy gap might just have vanished. This compound reveals a metallic or semimetallic behaviour (the increase of resistivity of our sample between 20° and 400° C was 20 per cent). While the pyrite modification of $PtBi_2$ is metallic but not superconducting[6], the hexagonal[7] high-temperature modification β-$PtBi_2$ is superconducting below 0·15° K (ref. 8).

In the nickel and palladium analogues we expect the transition to metallic properties to occur already for a lighter anion. Because of the difficulty in preparing stoichiometric samples the data for the marcasite-type

Table 1. Preliminary data for the energy gap ΔE, the thermoelectric power α and the magnetic susceptibility χ of ruthenium and osmium dichalcogenides. The energy gap was derived either from diffuse reflectance measurements (*opt.*) or from the temperature dependence of the electrical resistivity (*el.*), assuming $\rho \sim \exp(\Delta E/2kT)$

	ΔE (eV)	$\alpha_{300°\text{K}}$ (μV/°C)	$10^6\chi_m$(C.G.S./mol) Room temp.	Liquid N_2 temp.

$OsTe_2$	>0·2 (*el.*)	100 (*n*)	−44	

Table 2. Survey on the electrical properties of TY_2 compounds. The values for the energy gap ΔE were derived from resistivity measurements. Since the samples were not especially purified, all figures should be regarded as approximate only. α and β refer to different samples

	Structure type	ΔE (eV)	$\alpha_{300^\circ K}$ (μV/°C)	$10^6\chi_m$(C.G.S./mol) Room temp.	Liquid N_2 temp.
NiP_2	NiP_2	0·5	100 (n)		
$NiAs_2$	C18	~0·05 (ref. 1)			
$NiSb_2$	C18	Metallic (ref. 1)		~ −30 (ref. 5)	~ −30 (ref. 5)
PdP_2	NiP_2	0·6–0·7	100 (n)	α −6 β +5	
PdPAs	NiP_2	0·45	240 (n)		
$PdAs_2$	C2	Metallic	(p)	−45	−50
PdAsSb	C2	Metallic	(p)	−44	−50
$PdSb_2$	C2	Metallic	(p)	α −16 β −27	−15 −27
α-$PdBi_2$	Monoclinic	Metallic			
β-$PdBi_2$	$C11_b$	Metallic			
PtP_2	C2	⩾0·6	100 (p)	−27	(+32)
PtPAs	C2	⩾0·4	~10 (n,p)	−62	−59
$PtAs_2$	C2	0·5	200 (n)	−48	−45
$PtSb_2$	C2	⩾0·05	80 (p)	−56	−52
PtSbBi	C2	Metallic	1 (p)		
α-$PtBi_2$	C2	Metallic			
β-$PtBi_2$	Hexagonal	Metallic			

compounds $NiAs_2$ and $NiSb_2$ are perhaps not as yet conclusive, but PdP_2 is definitely semiconducting while $PdAs_2$ is metallic. Moreover, I have synthesized PdPAs and found that it still is non-metallic. It is isomorphous to PdP_2 and its lattice constants are: a = 6·88 Å, b = 6·03 Å, c = 6·41 Å, β = 126·1 deg. As seen from Table 2, the transition semiconductor → metal thus coincides with the change of crystal structure: The non-metallic palladium compounds crystallize in the monoclinic NiP_2 type of structure[9] the atomic positions of which have not yet been determined. However, because of their non-metallic behaviour NiP_2, PdP_2 and PdPAs must be polycompounds, that is, the co-ordination of their anions and cations must be essentially the same as in pyrite and marcasite.

It is remarkable that though palladium can adopt the configuration $d\varepsilon^6$ all pyrite-type palladium compounds are metallic and $PdSb_2$ is even superconducting below 1·25° K (ref. 10). $PdBi_2$ shows two modifications: monoclinic α-$PdBi_2$, which is superconducting below 1·75° K (ref. 11), and tetragonal β-$PdBi_2$ with a transition temperature of 4·25° K (ref. 11). The high-temperature modification β-$PdBi_2$ crystallizes in a strongly elongated $MoSi_2$ type of structure which still reflects the tendency of the anion to form a polycompound.

It would thus appear that in the metallic palladium and platinum compounds the $d\gamma$-levels dip into the $d\varepsilon$ band or into the valence band, thus giving rise to a high density of states favourable for the occurrence of superconductivity. For studying the factors which influence the conduction character, the pyrite-type compounds appear of special interest because the palladium compounds have almost the same lattice spacings as the platinum analogues: superconducting $PdSb_2$: $a = 6·452$ Å (ref. 12); semiconducting $PtSb_2$: $a = 6·441$ Å (ref. 12). Unfortunately, I was unable to prepare mixed crystals (Pd, Pt) Sb_2 either by melting or by sintering at 500° C. This behaviour seems to be significant because $PdSb_2$ readily forms mixed crystals with the superconductor $AuSb_2$ (a = 6·657 Å (ref. 12)) whereas the semiconducting $PtSb_2$ again does not.

I thank Prof. G. Busch, Swiss Federal Institute of Technology, Zürich, for kind permission to use his Gouy balance, and Dr. P. Giesecke, Cyanamid Stamford Laboratories, for some diffuse-reflectance curves, as well as Dr. E. Mooser and Dr. W. B. Pearson for valuable comments and discussions.

FORCED CONVECTIVE MASS TRANSFER IN ABSORPTION AND DESORPTION

By P. NORDON

C.S.I.R.O. Division of Textile Physics, Wool Research Laboratories, Ryde, Sydney

WHEN a stream of moist air is forced through a uniform bed of hygroscopic fibres such as wool, water is transferred from the air to the fibres or vice versa depending on the relative humidity of the air and the concentration of water already present in the fibres (regain). Simultaneous heat transfer occurs causing temperature changes in the air and the fibre bed.

It was shown by Cassie[1] that such a process is characterized by the propagation through the bed of two temperature fronts, one fast and one slow. Due to his assumptions of infinitely fast heat and mass transfer rates, Cassie's theory predicted that the shapes of these fronts (with respect to time) were the same in the fibre bed as at the boundary. Later work by MacMahon and Downes[2] elaborated the theory to take into account a finite rate of mass transfer the validity of which had been established[3,4] since the publication of Cassie's original work. In solving the differential equations pertaining to the problem, MacMahon and Downes assumed solutions in the form of fronts travelling through the bed at constant velocity. These assumptions necessarily limited the range of the solutions to cases where stable fronts are formed and to times when the steady state has been established.

Recent work[5] on heat transfer in beds of non-hygroscopic fibres has led to a re-examination of the more general problem of combined heat and mass transfer. For purposes of analysis a theoretical model was formulated also based on a finite rate of mass transfer but differing slightly from that introduced by MacMahon and Downes. Provisions were made in the model to allow for the non-linear isotherm of the wool–water system and for the heat of sorption as a function of regain. Introduction of these factors led to non-linear differential equations which were solved numerically by the method of finite differences with the aid of a computor (*Silliac* digital computor, Basser Computing Laboratory, University of Sydney). Only the main concentration profiles were calculated and their associated temperature changes (second fronts). A number of conclusions were deduced from this model which will be reported elsewhere together with the details of the calculations.

An interesting feature of the calculations is that some insight is gained into the vastly different behaviour of beds of hygroscopic fibres in absorption and desorption. The case examined is that of a wool bed of bulk density 0·1 g cm^{-3} and initially at 20° C through which air is forced, also at 20° C, at the rate of 15 cm^3 sec^{-1}/cm^2 bed cross-section. For absorption, the bed is initially dry and the air saturated at the initial temperature, while for desorption the wool is at saturation regain (33 per cent) and the air dry. Otherwise all conditions are identical, sorption hysteresis being neglected.

As shown in Fig. 1, there is a pronounced difference between the overall sorption and desorption curves calculated with the aid of the model. The rate of desorption is constant over most of the process and finally tapers off. Absorption is initially slightly faster than desorption; however, the rate decreases continually and soon becomes slower than desorption. Experiments with real wool beds yield similar results although the difference between the two cases is not as pronounced as in Fig. 1.

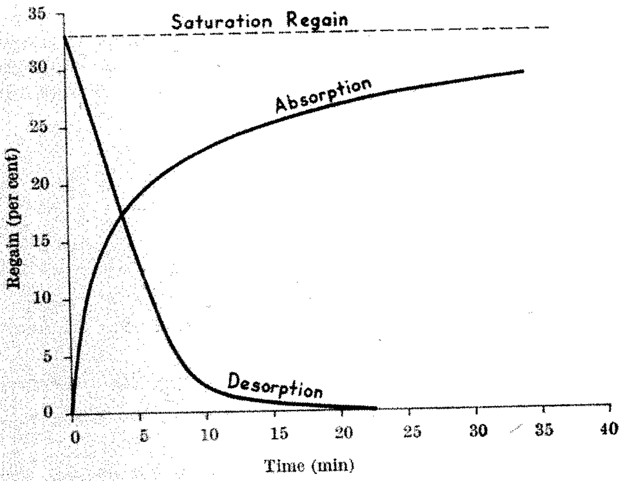

Fig. 1. Overall regain change for a wool bed, 1·5 cm deep during absorption and desorption

A more fundamental difference is revealed when the predicted temperature-time relationships for various bed positions are examined. It becomes apparent that a stable, progressive temperature front is formed in the case of desorption (Fig. 3) but not in the case of absorption (Fig. 2). The general shapes of the curves shown in Figs. 2 and 3 have been verified experimentally.

The explanation for these differences is interesting. For a given small amount of water transferred in the bed, the heat liberated (for absorption) or absorbed (for desorption) is the same and hence the rise or fall in temperature of both wool and air is the same for each case. If it is assumed that the rate of transfer is a function of the difference between the water vapour pressure in the air and the equilibrium vapour pressure of the water in the wool, then the change of temperature which occurs will cause a reduction in the rate of transfer, acting in both cases to reduce the rate. However, due to the exponential relation between the saturation vapour pressure of water and temperature, equal and opposite changes in temperature will not have the same effect in lowering or raising the equilibrium vapour pressure of water in the wool, the effect of an increase in temperature being always greater than that for a decrease. Hence absorption is slowed relatively more than desorption. The effect is cumulative, giving a slower overall absorption rate except at the beginning of the process.

The consequence of this behaviour on the bed as a whole is as follows:

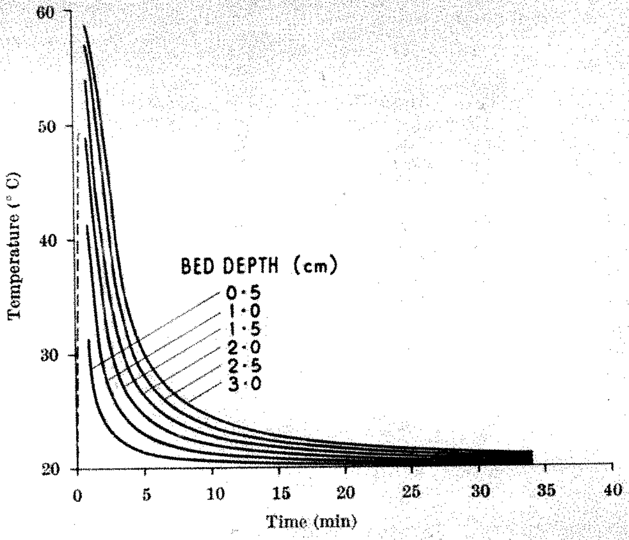

Fig. 2. Temperature at various depths in wool bed during absorption. – – –, approximate course, first front; ——, second front

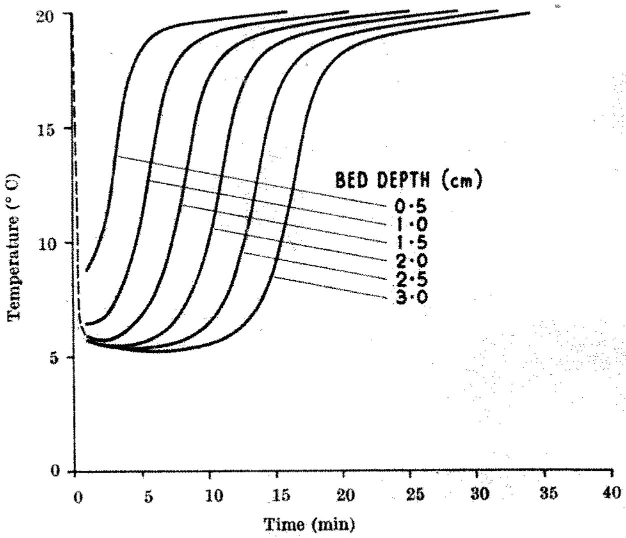

Fig. 3. Temperature at various depths in wool bed during desorption. – – –, approximate course, first front; —— second front

In desorption, so long as the concentration front is contained within the bed, air will emerge from it at an essentially constant temperature, slightly lower than the temperature of adiabatic saturation. Hence during this period the overall rate of desorption remains constant. The emergence of the front from the down-stream side of the bed is an indication that saturation is no longer achieved and the overall rate of desorption becomes smaller. The absorption curve is more complex and a full explanation will not be attempted here. To obtain a constant overall rate, all the moist air entering the bed has to be dried and this requires a much longer bed than that (3 cm) for which the calculation was made. If, therefore, a constant rate is observed at the beginning of absorption, it will last for a much smaller period than the constant rate of desorption for the same bed.

PHARMACOLOGICAL ACTION OF AJMALINE, THE POSSIBLE MECHANISM OF ITS ANTIARRHYTHMIC ACTION, AND ITS THERAPEUTIC POSSIBILITIES

By PROF. M. L. CHATTERJEE and M. S. DE
Department of Pharmacology, School of Tropical Medicine, Calcutta

AJMALINE is a major indoline alkaloid of *Rauwolfia serpentina* Benth. There are some conflicting reports on its pharmacological action, but gaps still exist in the knowledge, especially concerning its action on peripheral tissues, for example, plain, cardiac and skeletal muscles, and also about its behaviour towards neurotransmitter agents like acetylcholine.

Drugs which inhibit the action of acetylcholine on isolated muscles—smooth, skeletal and cardiac—have, according to Dawes[1], quinidine-like effects on heart. Vane[2] showed that paludrine, which has antiarrhythmic action, satisfies the findings of Dawes[1], and possesses, in addition, properties for potentiating the action of acetylcholine on some isolated tissues in small doses, while it itself shows cholinergic action in higher doses. Burn[3] indicated the role of such drugs on cholinergic receptors.

Antiarrhythmic property was discovered in ajmaline during routine screening by Arora and Madan[4] and this was corroborated by Schmitt and Schmitt later[5]; but the mechanism of its production is not yet known.

There is no information in the literature concerning the effect of ajmaline on the action of the neurotransmitter agents such as acetylcholine, adrenaline, noradrenaline, etc., to enable one to examine the foregoing hypothesis of Dawes[1] or Burn[3]. With the object of examining their views, effects of ajmaline on the action of acetylcholine, adrenaline and noradrenaline have been examined and the results are presented here. A comparison has also been made between these results with ajmaline and that of paludrine, as observed by Vane[2] and Burn and Vane[6], on the action of acetylcholine on isolated muscles.

The results presented here were obtained from the examination on isolated tissue preparations. Isolated guinea pig ileum was prepared and the dose of ajmaline which causes 50 per cent inhibition (ED_{50}) of the contraction due to acetylcholine in this tissue was estimated as suggested by Burn[7]. Seminal vesicles of guinea pigs were isolated after the method of Stone and Loew[8]. Other isolated preparations such as rectus abdominis muscle of frog (*Rana trigrana*), the heart of frog (for perfusion with frog Ringer solution through the sinus venosus) and the auricles of heart of guinea pig were prepared according to the method of Burn[7]. The effect of ajmaline in modifying the normal actions of acetylcholine, adrenaline, noradrenaline, etc., on these tissues was noted.

Ajmaline was dissolved in ethanol to make a 1 per cent solution, which was then suitably diluted with normal saline before use. Ethanol similarly diluted was always tested for control and its effect taken into account to get the true effect of the alkaloid. The neurotransmitter agents tested against were acetylcholine chloride (Hoff-

Table 1. ACTION OF AJMALINE ON SKELETAL, CARDIAC AND SMOOTH MUSCLES

Tissue examined	Conc. of ajmaline (g/ml.)	Effect of ajmaline alone	Effect of ajmaline on the action of acetylcholine (Ach)
Skeletal muscle of frog	10^{-6}	Nil (11/11)	Enhancement of contraction by Ach. Average 24·6 ± 6·38 per cent (6/6)
